This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

THE MARINE ENGINEER;

A MONTHLY JOURNAL OF

MARINE ENGINEERING, SHIPBUILDING,
STEAM NAVIGATION & ELECTRICAL ENGINEERING.

EDITED BY WILLIAM GEORGE NEAL,
Assoc. I.N.A.

Vol. XXI.—From April, 1899, to March, 1900.

London:
OFFICE FOR ADVERTISEMENTS AND PUBLICATION, 3, AMEN CORNER,
PATERNOSTER ROW, E.C.

1900.

INDEX.

EDITORIAL NOTES.

Amalgamation of all Naval Officers on board a Battleship, 1
Abnormal Stresses set up in the Plating, 49
Accident Insurance Business, 483
Actual Performance of Vessels under varying Conditions, 2
Adaptability of the Turbine System to Vessels of large size, 382
Americans and Submarine Torpedo-boats, 381
American Workmen and Labour-saving Tools, 241
American Yards seriously competing with British, 382
Anti-frictional value of Roller-bearings, 182
Apportionment of Damage between two Vessels in Collision, 182
Armour v. Guns, 382
Atlantic Cargo Steamers. Large, 181
Battleship, Launch of a, 241
Belfast and Messrs. Harland and Wolff, 242, 337
Berthon, Rev. Edward Lyon, 381
Boilers, Strength of, 2
Building of Ice-breakers, 485
"Bullfinch" Disaster, 183, 337
Calculation of Mid-ship and other Cross-section Areas, 49
Cargo-boat Machinery, Twenty Years of Progress in, 529
Circulation of Water in Boilers, 98
Collapsible Boat, the Berthon, 381
Comparison between the Performances of two Steamships 98
Compensation Act, Some Recent Decisions, 483
Competition of Colonial or Foreign Coalfields, 145
Connecting Rods in High-speed Engines, 337
Cylindrical v. Water-tube Boilers, 50, 530
Danish Ships, Some Steam Trials of, 2
Deadweight saved in an Atlantic Liner, 290
Dearth of Information as to Failures and Breakdowns, 425
Deck-plating, Shearing Stresses on the, 49
Development of Steam Turbines, 529
Disadvantages meted out to the Engineering Branch of the Royal Navy, 97
Disastrous Explosion on Board the T.B. Destroyer "Bullfinch," 183, 337
Distribution of Pressure over the Bottom of a Ship in Dry Dock and over the Dock Blocks, 181
Economy of Coals of the Schichau Engines, 99
Employees Short-sightedness, 242
Employers' Liability Insurance, 483
Engineer Corps of the United States Navy, 1
"Ermack," Ice-breaking Steamer, 485
Essentials for Large Cargo Steamers for the Atlantic, 181
Experimental Upper Turrets on U.S. Battleships, 338
Experiments on the Heat-absorption Power of Water, 98
Failures and Breakdowns, Experience as to, 425, 529
Far-reaching effects upon Marine Engineering Construction, 290
Forced Draught, a new method of, 181
Foreign Coalfields, 484
Fractures to Propeller Shafts, 181
Frictional Resistance of the Ordinary Collar-and-Ring Thrust-block, 182
"Fulda" Accident, The, 181
Graduates of Cambridge University and Engineering, 426
Hamburg-American Company's Yacht for First-class Passengers, 337
Harbour Commissioners of Belfast and Messrs. Harland and Wolff, 242, 337
Haythorn Water-tube Boiler on Passenger Steamers, 145
Heat-absorption Power of Water, Experiments on the, 98
High Rates of Speed, 241, 382
"Holland" Submarine Torpedo-boat, The, 381
Horse-power absorbed by Skin Friction and Wave Making, 50
Ice-breakers for Russia, 485
Important Decisions under the Compensation Act, 483
Increase of Size and Speed in War Vessels, 289
Insurance Rates in the Shipbuilding Trade, 483
Interesting Details of the "Turbinia," 382
International Maritime Conference, 182
Inventions and Improvements introduced in the U.S. between 1807 and 1850, 49
"Kearsage" and "Kentucky," U.S. Battleships, 338
Labour-saving Tools, Improvements in, 241
Large Atlantic Cargo Steamers, 181
Latest Products of the American Constructors' Skill, 338
Launch of a Battleship, 241
Limits of Over-sea Speed, 289
Local Industry in Ireland, 242, 337
"Lorna Doone" fitted with Water-tube Boilers, 145
Manacles Rocks, Stranding of the "Paris" on the. 97
Marine Engineering and Shipbuilding. Improvements in, 289
Maritime Conference, International, 182
Mechanical Inventions of Mr. Berthon, 381
Method of Performing Ship Calculations, 49
Motive Power. High-speed Steam Turbines, 529
Mounting of Naval Guns for Land Service, 530
Mumford Water-tube Boiler, 145
Naval Engineers and the War, 425
Newport News Shipbuilding Yard, 241
Novelty in the Construction of the "Kearsage" and "Kentucky," 338
Official Test of the "Holland" Submarine Torpedo-boat, 381
Output of Coal in the United States, 484
"Paris," Stranding of the. 97
Parsons Turbine Engine, 241, 382, 529
Performances of two Steamships. Comparison between the, 98
Perils of the Engine-room, The, 183, 337
Personnel of the United States Navy, 1
Possibilities of Forced Draught, 181
Possibilities of Ocean Navigation, 290
Practical Experience of the Strength of Boilers, 2
Pressure on Dry Dock Blocks, 181
Principles and the Work involved in the Launch of a Large Battleship, 241
Probabilities of Increased Steam Pressure, 290
Promotion of Engineer Officers in the Royal Navy, 97
Propelling Apparatus in a Destroyer, 289
Propulsion of Triple-screws, 426
Recognition for the Services of the Engineering Branch of the Royal Navy, 425
Recognition of Naval Engineers as a Royal Military Corps, 97
Relative Value of South African Coal, 145
Reminiscences of Early Steam Engines and Steam Navigation in the U.S., 49
Requirements of Engineering Employers, 426
Responsibility of Shipowners, 182
Scarcity and High Price of Coal, 484
Sea-going Engineers reticent of their Experiences, 425, 529
Serious Disaster to an Atlantic Liner, 97
Shipbuilding in the North of England and Scotland, 242
Skin Friction and Wave Making, Horse Power absorbed by, 50
Some Steam Trials of Danish Ships, 2
South African Coalfields. 145
Splendid Services rendered by Naval Engineers, 425
Steam Navigation at High Speeds, 289
Steering and Control of Torpedoes, 146
Strength of Boilers, 2
Strength of Connecting Rods, 337
Stresses in a Ship's Structure, 49
Submarine Torpedo-boats, 381
Surface Resistance of Vessels, 290
System of Forced Draught, 181
Thrust-block Friction, On, 182
Time and Money wasted by Shipbuilding Employees, 242
Torpedo-boat Destroyers, 99
Torpedo-boat Destroyers for Sea Service, 50
Torpedo-boats and High Speeds. 289
Torpedoes controlled by Invisible Rays, 146
Transmitting Motive Power by means of Light, 146
Trials of Vessels under different Conditions, 2
Triple-screw Propulsion, 426
Tubes of Water-tube Boilers, 530
"Turbinia," Speed of the, 290, 529
Turbo-motor Rotary Engine, 290
Twenty Years of Progress in Cargo-boat Machinery, 529
Type of Rod used in the "Bullfinch," 337
Types of Water-tube Boilers, 145
United States Navy and Engineers, 1
University Training and Engineering, 426
War Vessels, Increase of Speed in, 289
Water-tube Boilers and Turbine Engines, 241, 382
Water-tube Boilers in Passenger Steamers, 145
Wave Resistance, Increased, 290
Weight, Length and Speed of Vessels, 289
White, Sir William, on Steam Navigation at High Speeds, 289
Workmen's Compensation Act in Relation to the Shipping Trade, 483
Yacht for First-class Passengers, A new, 337
Yerrow Water-tube Boiler, 145

ILLUSTRATED ARTICLES.

Adjustable Lathe Mandrel, The X.L., 69
Ailsa Shipbuilding Co.'s New Graving Dock, 211
Air Compressors for Belt Driving, 110
Air-compressing Engine, 362
Air-pump, Drake's, 440
American Liner "Paris," 109
"Arcturus," Four Views on Board the R.M.S., 77 (double-page plate supplement)
"Argonaut," Trials and Experiments made in H.M.S., 53
Austrian Torpedo-boats, The, 26 (with double-page plate illustration)
Automatic Fairy Boiler Feeder, 221
Automatic Plug-making Machine, 435
Automatic Throttle Valve, Patent. 497
Babcock & Wilcox Marine Boiler, The, 387
Balanced Piston-Valve and its Application to Four-Crank Engines, A New, 530
Balancing of Engines, The, 17
Bearings for Propeller Shafting, 400
Bearing, The Mossberg Patent Thrust, 291, 492
Berth for Two Persons, First-class, on board R.M.S. "Arcturus," 77 (plate supplement)
Bickford Burner Co.'s Liquid Fuel Crucible Furnace, 131
Blackman Ventilating Co., The, 255
Boiler Arrangements of Certain Recent Cruisers, On the, 183
Boiler-room in the U.S. Cruiser "Chicago," 387
Boiler-shop, Messrs. Easton, Anderson and Goolden, Ltd., 307
Boiler, Water-tube, 503
Bulkhead Door for Ships' Holds, Watertight 252
Bull's Metal Propellers, 346
Burner for Industrial Purposes, 85
Cable Machinery for H.M.S. Cable Ship "Monarch," 362
Cable Steamer "Von Podbielski," Twin-Screw, 480
Casualties to Steam Pipes, 7
"Chicago," U.S. Cruiser, 387
Clyde Passenger Paddle Steamer "Waverley," The, 310
Clyde Piston Ring, The, 74
"Cobra," First-class Torpedo-boat, 26 (with double-page plate illustration)
Compensating Split Packing, 116
Compressed-air Machinery, 110
Copper Jointings. Seamless, 403
Cork Insulation, Nonpareil, 438
Cornish's Marine Sounding Machine, 499
Cowper-Coles Magnetic Scale Collector, 254

Cowper-Coles Sound Locator and Projector, 347
Crawford's Patent Watertight Bulkhead Door for Ships' Holds, 252
Crosby Indicators, 150
Crucible Furnace, Liquid Fuel, 131
Cunliffe & Croom's Duplex Vertical Milling Machine, 158 (with page plate supplement)
Cylindrical Marine Water-tube Boiler, Drake's, 443
Daimler Oil Motor, 119
"Danske-Tre," Self-trimming Lighter, 220
Deck Planer, Electric, 339
Diagrams from Triple-expansion Engines, Some interesting, 168
Door Hook and Eye, An Improved, 538
Drake's Air Pump, 140
Drake's Bearings for Propeller Shafting, 400
Drake's Cylindrical Marine Water-tube Boiler, 443
Drilling, Boring, Tapping and Milling Machine, Radiating, 257
Drilling Machines, Electric, 338
Drop Rudder, Patent, 882
Dry Dock at Limehouse, The New Union, 263
Duncan's Patent Automatic Throttle Valve, 497
Duplex Vertical Milling Machine, 158 (with page plate supplement)
Durston, Sir John, On Trials and Experiments made in H.M.S. "Argonaut," 53
Dynamo Testing Shop, Messrs. Johnson & Phillips, 350
East Asiatic Co.'s S.S. "Korea," 505
Easton, Anderson & Goolden, Ltd., 307
Edson Recording Gauge, The, 532
Electric Deck Planer, 339
Electric Drilling Machines, 338
Electric Fan, 364
Electricity in Shipbuilding Yards, Some notes on the application of, 338
Electric Launches, "Vril," 266
Electro-Magnetic Separator, Patent, 384
Emigrants' Berth on Board R.M.S. "Arcturus," 77 (double-page plate supplement)
Engines of S.S. "Manchester Corporation," 158 (with page plate supplement)
Engines, The Balancing of, 17
Engine, The "Petter" Petroleum, 299
Estler Bros., Improved Ships' Lamps, 397
Expansion Gland for Steam Pipes, 304
Experiments having Reference to the Durability of Water-tube Boilers, Some, 201
Experiments on the Heat-absorption Power of Water, 99
Fans for Ventilating, 255
First-class Battleship "Vengeance," 152
First-class Saloon on Board R.M.S. "Arcturus," 77 (double-page plate supplement)
Fletcher, Son & Fearnall, Limited, Union Docks, Limehouse, 263
Forced Draught, Gosling's, 146
Fox Tube or Pipe Cutting Machine, The, 888
Friedmann's Patent Re-starting Injectors, 69
Friedmann's Sight-feed Lubricators, 66
Gauge, Recording, 532
Gauge, Viles' Patent Water, 60
Gland for Steam Pipes, Expansion, 304
Gosling's Forced Draught, 146
Graving Dock, Ailsa Shipbuilding Co.'s New, 211
Heat-absorption Power of Water, Experiments on the, 99
Heating Devices, Simple, 296
"Hezzanith" Parallel Rule, The, 64
Holden & Brookes' "Sirius" Pulsating Pump, 209
Homacoustic System of Voice Tubes, 268
Hook and Eye, An Improved Door, 538
Hose Union, "Storz" Patent, 213
Hulburd's Seamless Copper Jointings, 403
"Ikadsuchi," Torpedo-boat Destroyer, 3
Indicator for Steam Engines, A Continuous Mean-Pressure, 426, 510
Indicators, Crosby, 150
Injectors, Friedmann's Re-starting, 69
Installations, Compressed Air, 110
Institution of Engineers and Shipbuilders in Scotland, Paper read before the, 530
Institution of Mechanical Engineers, Papers read before the, 243, 426
Institution of Naval Architects, Papers read before the, 7, 53, 183, 201
Japanese Torpedo-boat Destroyer "Ikadsuchi," 3
Japanese Torpedo-boat Destroyer "Murakumo," The, 53
Johnson & Phillips, 350
Kerosene Combination Hot-blast Hand-brazer, 296
"Korea," The S.S., 505
Lamps, Improved Ships', 397
"Lancaster" Patent Piston-Valve Packing, 538
Lathe Mandrel, The X.L. Adjustable, 69
Launches, "Vril" Electric, 266
Launch for the War Office Submarine Mine Service, 166
Lighters for Self-Trimming, New Steel, 220
Liquid Fuel Crucible Furnace, 131
Lubricators, Sight-feed, 66
Machinery of H.M.SS. "Proserpine" and "Psyche," 243
Machine Shop, Messrs. Easton, Anderson & Goolden, Ltd., 307
Machine Shop, Messrs. Johnson & Phillips, 350
Magnetic Scale Collector, Cowper-Coles, 254
"Manchester Corporation," Engines of S.S., 158 (with page plate supplement)
Mandrel, The X.L. Adjustable Lathe, 69
Marine Boiler, the Babcock & Wilcox, 387
Marine Oil Motor, Priestman's, 119
Marine Sounding Machine, A New, 499
Marshall, F. T., On the Boiler Arrangements of certain recent Cruisers, 183
Mayston, Mr. Robert, R.N., On the Machinery of H.M.SS. "Proserpine" and "Psyche," 243
Mean-Pressure Indicator for Steam Engines, A continuous, 426, 510
Milling Machine, Duplex Vertical, 153 (with page plate supplement)
Milton, Mr. J. T., On Steam Pipes, 7
Moeller & Condrup's New Burners, 85
Mossberg Patent Thrust Bearing, The, 291, 492
Multiple-Expansion Engines, Receiver Drop in, 485
"Murakumo," The Japanese Torpedo-boat Destroyer, 53
Neville Bros. Drilling, Boring, Tapping and Milling Machine, 257
Nonpareil Cork Insulation, 488
North British Steam Packet Co.'s P.S. "Waverley," The, 310
North-East Coast Institution of Engineers and Shipbuilders, Paper read before the, 485
Nottingham Universal Automatic Fairy Boiler Feeder, The, 221
O'Brien, Mr. William, on a New Balanced Piston-Valve and its Application to Four-crank Engines, 530
Oil Engines, 102
Oil Launch, 865
Oil Motor Boats, 119
On the Boiler Arrangements of certain Recent Cruisers, 183
"Oriental" Dry Dock and Works, Shanghai, 310
Packing, Compensating Split, 116
Papers read before the Institution of Naval Architects, 7, 53, 183, 201
"Paris," The stranded, 109
"Petter" Petroleum Engine, The, 299
Phillips's Water tube Boiler, 503
Pipe-cutting Machine, The Fox Tube or, 383
Pipes, Steam, 7
Piston Ring, The Clyde, 74
Piston-Valve and its Application to Four-crank Engines, A New Balanced, 530
Piston-Valve Packing, An Improved, 538
Platts & Lowther's Patent Compensating Split Packing, 116
Plug-making Machine, Automatic, 435
Priestman's Marine Oil Motor, 119
Propellers, Bull's Metal, 346
Propeller Shafting, Bearings for, 400
"Proserpine" and "Psyche," Machinery of H.M.SS., 243
Pulsating Pump, The "Sirius," 209
Radiating, Drilling, Boring, Tapping and Milling Machine, 257
Receiver Drop in Multiple-Expansion Engines, 485
Recording Gauge, The Edson, 532
Re-starting Injectors, Friedmann's, 69
Reversible Propeller, Patent, 102
Ripper, Prof. William, On a Continuous Mean Pressure Indicator for Steam Engines, 426, 510
Roller Thrust Block, Mossberg's Patent, 291, 492
Rudder, Patent Drop, 382
Rule, The "Hezzanith" Parallel, 64
Russian Dredger, "Titus Edrigevitch," 84
Scale Collector, Magnetic, 254
Seamless Copper Jointings, 403
Separator, Patent Electro-Magnetic, 384
Shanghai Engineering, Shipbuilding and Dock Co.'s "Oriental" Dry Dock and Works, Shanghai, The, 310
"Sheldrake," H.M.S., Fitted with four Babcock & Wilcox Boilers, 387
Shipbuilding and Docking Facilities of Troon, 211
Shipbuilding Yards, Some Notes on the Application of Electricity in, 338
Ship Lighting Set, Messrs. Johnson & Phillips, 350
Ships' Lamps, Improved, 397
Sight-feed Lubricators, Friedmann's, 66
Simple Heating Devices, 296
Simpson, Strickland & Co., 542
"Sirius" Pulsating Pump, The, 209
Smith & Wilford's Automatic Fairy Boiler Feeder, 221
Smoke Room, A corner of the, on board R.M.S. "Arcturus," 77 (with plate supplement)
Some Experiments having Reference to the Durability of Water-tube Boilers, 201
Some Interesting Diagrams from Triple-Expansion Engines, 168
Sounding Machine, A New Marine, 499
Sound Locator and Projector, Cowper-Coles, 347
Special Machine Tool for Shipbuilding Requirements, 153 (with page plate supplement)
Steam Engines, A Continuous Mean-Pressure Indicator for, 426, 510
Steam Pipes, 7
Steam Pipes, Expansion Gland for, 304
Steam Trap, The Thermoscopic Loop, 401
Steel Lighters for Self-trimming, New, 220
Stone & Co.'s Automatic Plug-making Machine, 435
"Storz" Patent Hose Union, The, 213
Taylor's Patent Door Hook and Eye, 538
Teak Launch, Copper Sheathed, with five B.H.P. Balanced Engines, 163
Thermoscopic Loop Steam Trap, The, 401
Thornycroft, John I. & Co., 51
Throttle Valve, Patent Automatic, 497
Thrust Bearing, The Mossberg Patent, 291, 492
"Titus Edrigevitch," The Dredger, 84
Tolch & Co., of Fulham, 102
Torpedo-boat Building on the Thames, 51
Torpedo-boat Destroyers, 3, 53
Trials and Experiments made in H.M.S. "Argonaut," 53
Triple-Expansion Engines of S.S. "Manchester Corporation," 158 (with page plate supplement)
Triple-Expansion Engines, Some interesting Diagrams from, 168
Triple-Expansion Launch Engines, 542
Tube or Pipe-cutting Machine, The Fox, 383
Tubes, Homacoustic System of Voice, 268
Twin-Screw Cable Steamer "Von Podbielski," 480
Union Docks, Limehouse, 263
"Vengeance," H.M.S., 152
Vertical Petroleum Engine, 299
Vile's Patent Water Gauge, 60
Voice-Tubes, System of, 268
"Von Podbielski," Twin-Screw Cable Steamer, 480
"Vril" Electric Launches, 266
Water Gauge, 60
Watertight Bulkhead Door for Ships' Holds, Crawford's Patent, 252
Water-tube Boiler, Cylindrical Marine, 443
Water-tube Boiler, Phillips's, 503
"Waverley," The Clyde Passenger Paddle Steamer, 310
Weighton, Prof. R.L., On Receiver Drop in Multiple-Expansion Engines, 485
X.L. Adjustable Lathe Mandrel, The, 69
Yarrow, A. F., On the Durability of Water-tube Boilers, 201
Yarrow-Schlick-Tweedy System of Balancing of Engines, 17

GENERAL INDEX.

Additions to the Fleet, 509
Adjustable Lathe Mandrel, The X.L., 69
Ailsa Shipbuilding Co.'s New Graving Dock, 211
Air-compressing Engine, 362
Air Compressors for Belt Driving, 110
Air Pump, Drake's, 440
American and Swedish Navy Estimates, The, 23
American Liner "Paris," 109
"Amphitrite," The Trials of the, 73
Appointments, Naval Engineer, 31, 78, 123, 160, 224, 272, 316, 356, 405, 467, 513, 549
"Arcturus," Four Views on Board the R.M.S., 77
"Argonaut," Trials and Experiments made in H.M.S., 53, 66

Printed for the Proprietors by PERRY, GARDNER & Co, Foresters' Hall Place, Clerkenwell Road, London, in the County of Middlesex, and Published at the Offices, 3, Amen Corner, Paternoster Row, in the Parish of Christ Church, in the City of London.—March 1st, 1900.

The Marine Engineer.

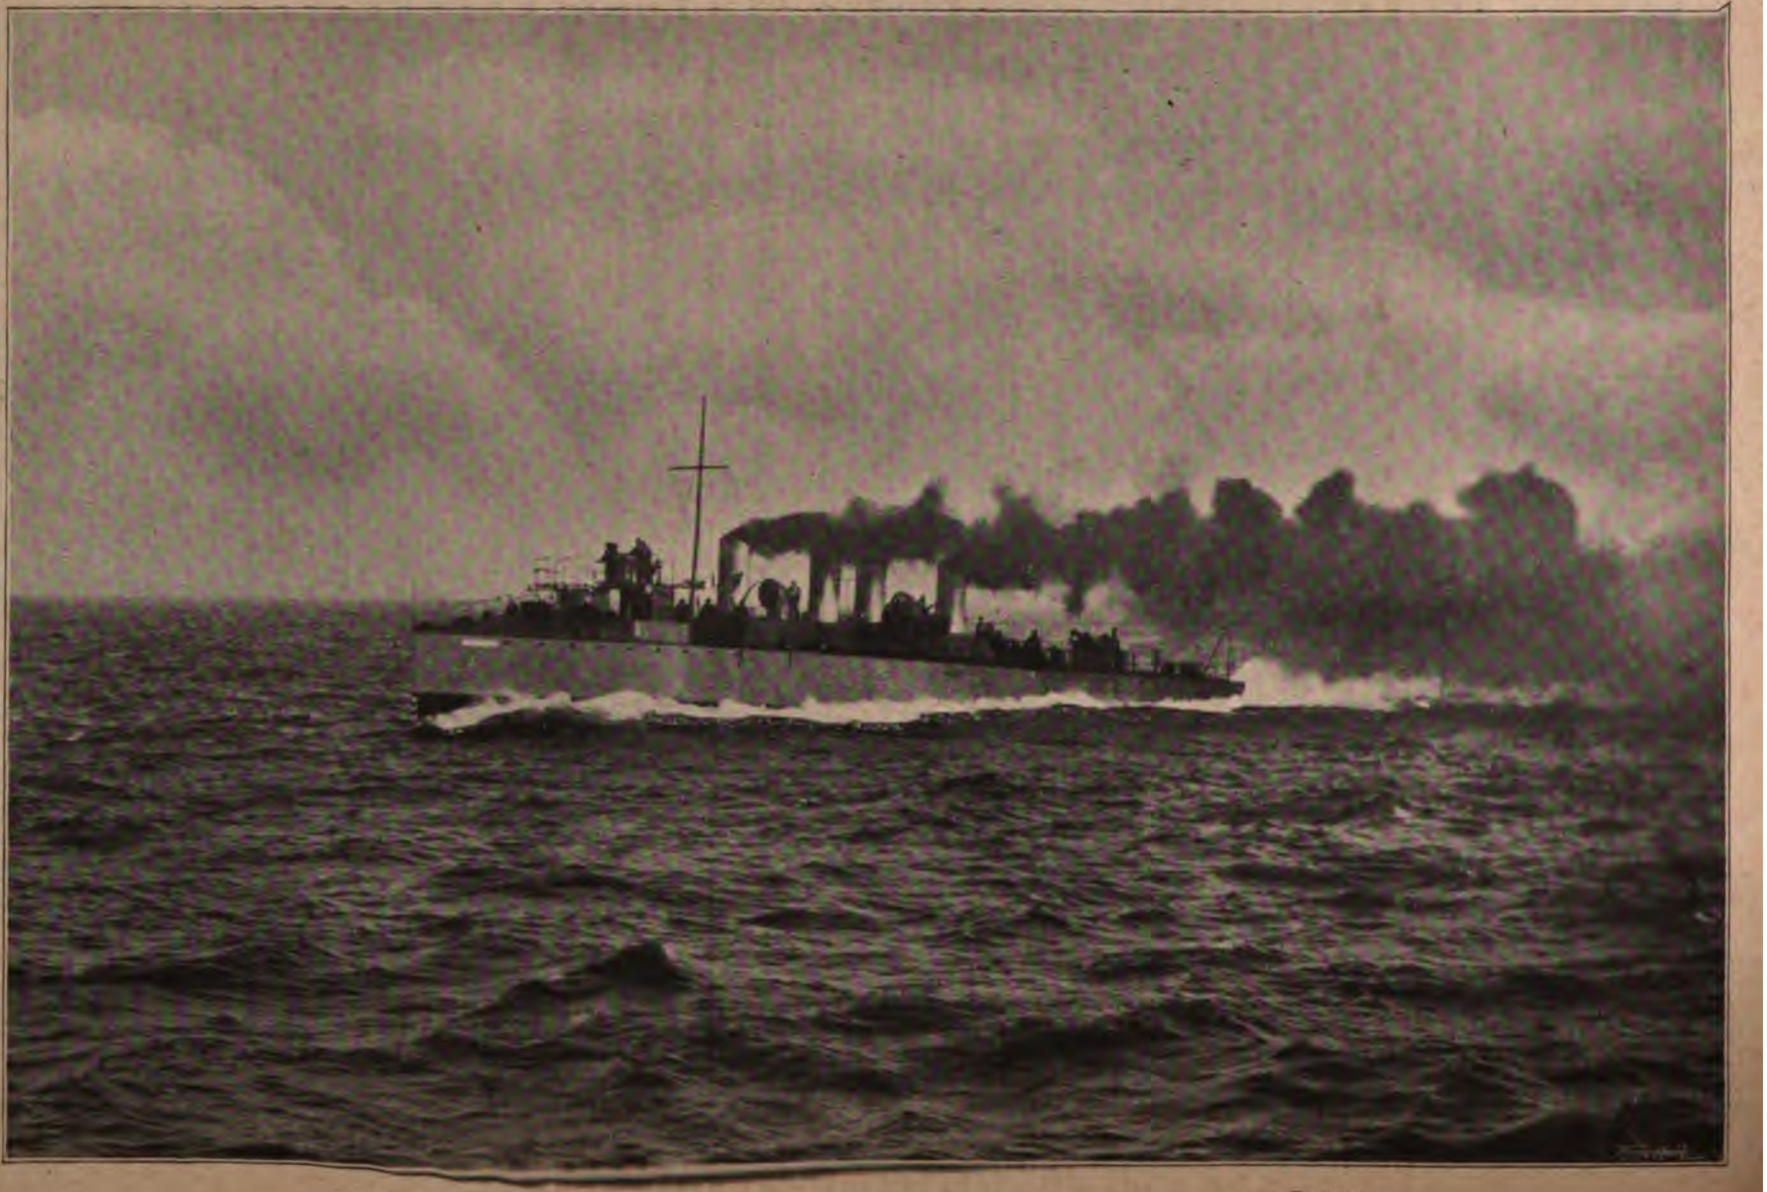
LONDON, APRIL 1, 1899.

THE United States have at last made a decided move to place the Engineer Corps of the Navy upon a proper footing as regards the service officers in the form of a Bill prepared by the Naval Committee and presented to the House of Representatives. This Bill goes to the whole root of the matter, as to relative equality, by an actual amalgamation of what they call officers of the line, or as we should term them executive officers, and the engineer corps of the Navy. In the *North American Review* of December, 1898, the Hon. Francis Wilson, late member of the Naval Committee; the Hon. Theodore Roosevelt, late assistant secretary of the Navy; Commodore John W. Philip, U.S.N.; Commodore George W. Melville, engineer-in-chief U.S.N.; and the Hon George Edmund Ross, chairman of the sub-committee on *personnel* of the Navy, give their personal views of the proposed Bill, and in all cases in favour of it. The amalgamation of all naval officers on board a battleship is a startling solution of the problem, as it implies that all naval officers must be trained to take efficient charge in the engine-room, whilst all engineer officers are to be equally competent at need to take command on the bridge, and have equal executive control over the discipline of the men under them as the other executive officers.

The arguments advanced for this solution are very strong and well worth attention. The Hon. Roosevelt states that "every officer on a modern war vessel in reality has to be an engineer whether he wants to or not. Everything on such a vessel goes by machinery, and every officer, whether dealing with the turrets or the engine-room, has to do engineers' work. There is no longer any reason for having a separate body of engineers responsible for only a part of the machinery. What we want is one homogeneous body, all of whose members are trained for the efficient performance of the duties of the modern line officer. In making this change we are not making a revolution; we are merely recognizing and giving shape to an evolution which has come slowly, but surely and naturally; and we propose to reorganize the Navy along the lines indicated by the course of the evolution itself." The work of the Department in detailing officers for duty will be vastly simpler under the new scheme than it has been in the past, because every officer of the new line will be capable of performing any of the duties which involve the management of large bodies of men or the control of machinery. The *personnel* thus becomes much more elastic, and an end is put to an enormous amount of petty bickering inevitable under the present system. It is believed in the U.S. that this new amalgamation of services will give a navy whose *personnel* has an efficiency far ahead of that of any other country. The Bill also provides for compulsory retirement at a certain age or seniority, so that officers may be advanced to responsible commands within the age of best efficiency. Also warrant rank is to be given to the best mechanicians as an encouragement to the rank and file of the engineer's force. Commodore Melville points out the evolution that has been going on for years in the character and material of the Navy wrought by a single agency, steam, whilst the *personnel* in its fundamental distinctions and classifications has only been half-heartedly following such evolution. On the fighting ship, the fighting man must stand supreme; but he must know how to handle his tools and must change as his ship changes, so that, precisely as he once knew about sails, now he must know about engines. In former days the sea soldier who had once commanded his troops afloat, soon had to become also a sailor man, so now the service officer and the engineer must become one. In short it is absolutely essential that the best naval officer of the future shall be proficient in engineering. Where engineer officers now control from 25 per cent. to 50 per cent. of the crew it is absurd not to rank them equally with other officers as executive and fighting officers. In the sixteenth century, war vessels carried 50 per cent. of their force as soldiers pure and simple. Masters and their mates long existed as a distinct department for the navigation of the vessel. Force of circumstances has gradually caused the absorption of all distinct departments of navigation, gunnery and fighting in the executive of the fleet, marines being now but a fragmentary relic of what was once the original fighting force on board ship; now the evolution is extending to the absorption by the general executive officers of the necessary knowledge in mechanics and engineering. In the U.S. this amalgamation will be fairly easily carried out, as the naval cadets at present, whether for the Line or for the Engineering Corps, follow the same training for three years of their curriculum; and line officers have, in passing for promotion, to undergo an elementary examination in engineering. This thorough and manly mode in the U.S. of recognizing the evolution of the needs of the modern iron-clad Navy is well worth the consideration of our Admiralty and Government. The importance and value to a modern fighting vessel of the engineers, officers, and men can no longer be ignored, and it may be easier and more agreeable to the *amour propre* of the older executive service to themselves become engineers, and thus to absorb what they can no longer ignore, rather than to apparently concede executive power and rank to those they have so long considered non-combatants, and therefore subordinates. In one way or another the amalgamation of the different branches of the service must be effected soon in the British Navy, either by the levelling up of the lower to the higher, or by the absorption of the smaller by the greater. In either case it will not be long before an engineer stands on the bridge and has the full executive control of that position.

Some steam trials of Danish ships communicated by Captain A. Rasmussen, of the Engineering Department of the Royal Danish Navy, to the Institution of Naval Architects, contains some valuable information as to the actual performance under varying conditions, and best conditions of efficiency under some of these conditions, of a torpedo-boat 145 ft. 6 in. in length and of 140 tons' displacement. The particulars investigated may be divided into six heads, viz. :—1st, determination of the maximum speed, the full-power speed for a continued three-hours' run, and the sea speed at normal draught and at a standard depth of water for a trial of at least 12 hours' duration; 2nd, speed trials for the determination of the curves of H.P. and revolutions at normal draught and at different depths of water; 3rd, speed trials for the determination of the above-named curves at the standard depth of water and at different displacements; 4th, coal-consumption trials for the determination of the most economical use of the propelling machinery with different numbers of boilers and engines in use; 5th, trials for determining the time necessary for raising steam and getting under way; 6th, determination of the power of the propeller to decrease and increase the speed of the vessel. It is obvious that when all these facts have been ascertained about any vessel, and we understand 80 double runs on the measured mile were made to determine the curves and 1,800 indicator diagrams taken on the trial, there is not much else worth knowing about such vessel. The records of such exhaustive trials for leading types in our own navy would place in the hands of our commanders such knowledge, under the advice of the engineer-in-chief, as would enable such commander to get the most out of his vessel under any circumstances. In the case in point, given by Captain Rasmussen, the torpedo-boat *Söbjörnen*, whilst giving a maximum speed in two consecutive runs over the measured mile of 23·6 knots, fell to 23·3 knots on a three-hours' full-power trial, and to 18·9 as a sea-speed of at least 12 hours' duration, with necessary fire-cleaning. Under test No. 2 the effects of varying depths of water produced strange effects upon the speed of the boat. At half-power the loss of speed in shallow water is very great, dropping from 18·6 knots in 20 fathoms to 13·1 knots with the same power in 2½ fathoms. At full speed, however, the reverse is the case, full speed of 23·6 knots in 20 fathoms rising to 24·1 knots in 2½ fathoms, and falling to its worst of 22·8 knots in eight fathoms. This would be important to a commander endeavouring to escape an enemy. At top speed seek the shallowest water, and beware of eight fathoms with a draught such as that of this torpedo-boat. Under trial three it was found that the deeper the immersion the greater the H.P., which can be developed with constant cut-off; but the corresponding H.P.'s are higher, the greater the displacement, and with constant H.P. the speed is less as the displacement increases, which is what might be expected. Under test four, for coal-consumption, this may be divided into the constant consumption due to radiation from engines, pipes, boilers, &c., loss by ashes, and by some auxiliary engines, and the effective consumption for speed. The constant consumption is approximately proportional to grate-area, and the effective consumption directly proportional to I.H.P. up to the limit at which forcing the boilers commences. Beyond this point the *ratio* of consumption increases more rapidly than the H.P. Under test five it was remarked the time necessary for getting under way with water-tube boilers much depends on the time necessary for warming the engines; hence steam-jackets are necessary in large engines. In the case in point engines were started from cold water in 24 minutes and full speed attained in 33 minutes. Under test six as to the effect of the propeller to increase or decrease the speed of the vessel, the important result learned was that as regards time required to attain any given speed, the higher the speed to be attained the quicker the time in attaining it, and similarly on reversal; the higher the speed at the moment of reversal with the same speed of revolution the quicker the time in which the vessel was brought to rest, though naturally a longer distance is traversed in the shorter time for reversal at a high speed than at a lower one. The whole series of tests are most interesting.

Mr. Stromeyer, Chief Engineer of the Manchester Steam Users' Association, contributes also to the Institution of Naval Architects a most useful paper on practical experience of the strength of boilers which we regret that want of space prevents us doing full justice to. Mr. Stromeyer very pertinently puts it that, though general practice and particularly marine practice under the rules of the Board of Trade and of Lloyd's Register invariably produce safe boilers, the accepted rules and formulæ actually prevent us know-



The Japanese Torpedo-Boat Destroyer "Ikadsuchi," built by Messrs. Yarrow & Co., Ltd., London.

ing how much material we may waste in over-safety with the accompanying commercial disadvantage of over-weight. From the exceptional personal experience of the author in all varieties of failures of boilers he has come to the conclusion that experience as to the practical strength of boilers, flat plates or furnaces is still wanting, as no one would wilfully design or watch a weak boiler to find out by disaster how weak it was. Owing to the prevalence of lap-rivetted joints in flues no such furnace is truly cylindrical and unavoidable oval shapes and stresses are set up due to heat and longitudinal deformation. Nevertheless the author considered accepted formulæ for the resisting strength of furnace flues to be much underestimated and that collapse seldom ensues from direct crushing but from other subsidiary causes often overlooked—as the weakness of the flue from accepted formulæ is often much exaggerated. Details of many cases of collapse are dealt with, and the many important tests tabulated at the end of this paper form a most valuable paper of reference to those desiring practical checks upon accepted formulæ in the construction of boilers.

THE JAPANESE TORPEDO-BOAT DESTROYER.

MESSRS. YARROW are completing their order of six 31-knot destroyers for Japan. On December 11th a preliminary trial over the Maplin measured mile was run by the first of them, the *Ikadsuchi*, which we illustrate on page 3. She is a twin-screw boat of 220 ft. long, 20 ft. 6 in. beam, and propelled by two sets of four-crank triple-expansion engines balanced on the Yarrow, Schlick & Tweedy principle. The cylinders are 20½ in., 31½ in., and two low-pressure cylinders of 34 in. diameter, the stroke being 18 in. diameter. The steam is supplied by four Yarrow boilers. On trial the contract load of 35 tons was carried, and the contract speed of 31 knots was more than reached during four runs. The engines are designed to give 6,000 H.P., but it is estimated that 7,000 I.H.P. could be reached. The steam pressure was 185 lbs.; revolutions, 410 per min.; and the draught of the destroyer, 8 ft. 6 in. The armament consists of one 12-pounder quick-firing gun, mounted aft, and five six-pounder guns, and there are two torpedo-guns on deck for 18 in. torpedoes. The coal capacity is 90 tons, which would carry the boat across the Atlantic.

THE PREVENTION OF COLLISIONS AT SEA.

IT is perhaps no exaggeration to say that, of late years, there has been more destruction of life and property at sea, by collisions, than by any other cause. Since the advent of big steamers and high speeds, the risk of collision has been enormously increased, and we have pleasure in giving some particulars of an invention to prevent or minimise this source of disaster, namely, Anthony's Sound Locater.

This ingenious appliance is designed on scientific principles, and by its use on board ship the position of any steamer or lighthouse in the vicinity can be accurately indicated by the sound of the fog signal. An important feature of the invention is a large circular-mouthed sound collector, attached to which is a resonator against which the sound beats, and a cowl-shaped receiver, down which the sound travels from the resonator to the ear tubes.

Owing to the fact that the "receiver" end of the instrument is narrower than the "collector" end, the sound increases in volume as it passes through There is a dial placed on a suitable pedestal, and when the sound collector is revolved, the exact position at which the operator has found the object of his search is registered thereon.

The instrument has undergone many severe tests in the hands of experts, and the tests on every occasion have given satisfactory results. The fact that a large number of orders for the appliance have already been received, and that enquiries are still coming to hand from all parts, is a sufficient proof that the shipowners of the country have not been slow to discern its merits. The appliance has been patented by the inventor, Mr. James Anthony, Hamburg Chambers, Newcastle, and we believe a syndicate has been formed to undertake its manufacture and sale.

INSTITUTION OF NAVAL ARCHITECTS.

THE spring meeting of the Institution of Naval Architects took place on March 22nd, 23rd, and 24th in the hall of the Society of Arts, John Street, Adelphi, under the presidency of the Right Hon. the Earl of Hopetoun, G.C.M.G. Among those present were Sir William White, Sir John Durston, Sir Raylton Dixon, Sir E. J. Reed, Sir John Hay, Sir Benjamin Browne, Vice-Admiral Sir N. Bowden-Smith, Mr. J. Williamson, Director of Dockyards, Professor Elgar, Professor Biles, Messrs. J. I. Thornycroft, James Dunn, Andrew Laing, A. Betts Brown, James Thomson, J. Riley, Macfarlane Gray, B. Martell, J. T. Milton, J. Hamilton, J. M. Gray, F. K. Barnes, F. P. Purves, A. E. Seaton, J. H. Ellis, John Corry, Admiral Morant.

The President opened the proceedings by calling upon the secretary, Mr. George Holmes, to read the annual report of the Council. The Secretary then read as follows:—

"The Council are glad to report that, in the year which has just elapsed, the Institution has continued to prosper. The total receipts, as given in the accompanying statement, are somewhat less than in the preceding year. This is due to the fact that no summer meeting was held in 1898, and consequently less was received under the heading of entrance fees than in some recent years. The receipts from the permanent sources of income continue to be satisfactory. On the other side of the account, in consequence of temporary extra expenditure involved by the Congress, such, for instance, as the publication of an extra volume of the transactions, the disbursements last year were above the average.

"During the year, sixty-four new members were elected, while the losses due to deaths and withdrawals amounted to forty, leaving a net gain of twenty-four.

"The Council beg to inform the members that the President of the Institution, the Earl of Hopetoun, has lately been appointed by the Queen to fill the high office of Lord Chamberlain. They now announce with great pleasure that Lord Hopetoun's acceptance of this office will not entail the loss of his invaluable services to the Institution.

"The Council have much satisfaction in stating that they have received and accepted cordial invitations from the Mayor and Corporation of Newcastle-on-Tyne and the President and

Council of the North-East Coast Institution of Engineers and Shipbuilders to hold a meeting of our Institution at Newcastle-on-Tyne during the coming summer. Particulars of this meeting will be announced in due course.

"Under the regulations of the Committee of Lloyd's Register relating to the constitution of their sub-committee for surveyors, it became necessary last January to elect four representatives of this Institution on that committee. The Council accordingly elected Mr. James Dunn, Mr. Francis Elgar, LL.D., F.R.S., Mr. John Sampson, and Mr. Albert E. Seaton. These gentlemen have kindly consented to place their services at the disposal of the Institution.

"The Council have had great pleasure in awarding a gold medal to Professor Captain Kriloff, for his very able papers on 'The General Theory of the Oscillations of a Ship on Waves,' and 'On Stresses Experienced by a Ship in a Seaway'; and also to Professor Hele-Shaw for his two exceptionally valuable papers, describing his remarkable 'Investigation of the Nature of Surface Resistance of Water and of Stream-Line Motion under certain Experimental Conditions.' The Council feel that they are greatly indebted to Professor Hele-Shaw, who is not connected with the Institution, for freely placing the results of his prolonged investigation at the disposal of the members, and for publishing the results through the medium of our transactions.

"The Council have had for some time under consideration the rules for the election of members and associates. They have come to the conclusion that it is to the interests of the Institution that those rules should now be made somewhat more stringent, and that provision should be made for a class of associate members, intermediate between full members and associates. The proposed new rules, copies of which have been sent to all members and associates, will be submitted for adoption at the present meetings.

"Last summer the Council received a letter from the President of the Société des Ingénieurs Civils de France, inviting the presence of delegates of the Institution at the celebration of the fiftieth anniversary of the founding of the Société. The Council gratefully accepted the invitation, and their delegate was received with the kindness and hospitality which the French institution have always shown in their relations with our body.

"The Council deeply regret to announce the death of one of the vice-presidents of the institution, the late Mr. W. H. Tindall, Chairman of Lloyd's Register, and also of Sir William Gray and Mr. William Laird, members of Council. Since the last meeting the Institution has also lost one of its most distinguished foreign members, Herr Alfred Dietrich, constructor-in-chief of the Imperial German Navy, whose services to the Institution on the occasion of our visit to Berlin are fresh in the memories of all who took part in the German meetings. Herr Dietrich was a Gold Medallist of the Institution. The Institution has also to deplore the loss of Sir William Anderson, K.C.B., member, and of Sir John Fowler, K.C.M.G., associate, both eminent civil engineers; and of Messrs. W. B. Baskcomb, J. Brodie, W. McLaren, and J. Westwood, jun., members, and Lucas Thomasson, associate."

The President then delivered his opening address:—

"From the report which has just been read you will have gathered that the year 1898 has been less eventful than some of those which have preceded it. Nevertheless, much useful work has been done, and for the first time in the history of the Institution we have published two volumes of the transactions in one year.

"I deeply deplore the fact that the hand of death has lately been so busy in our ranks. Since last I had the pleasure of addressing you we have lost a vice-president and two members of Council, as well as a member and an associate of the Institution, who were amongst the most prominent engineers in the country, and also another member who had attained to the highest degree of eminence in his profession in his native land—Germany. Our late vice-president was chairman of Lloyd's Register—a most important position, which Mr. Tindall filled in an admirable manner. Of the two members of Council whom we have lost the name of one, Mr. William Laird, of Birkenhead, is known so well that I need hardly enlarge on his career at any great length. Mr. Laird was the head of a famous firm which was identified with the first introduction of iron shipbuilding. His father, the late Mr. John Laird, was one of our earliest vice-presidents; his brother, the late Mr Henry Laird, was a most valued member of Council; and I can say of Mr. William Laird that he has worthily maintained the traditions of his family. I am glad to say that the family of the Lairds is not deserting the Institution, as I notice that you have just elected as an associate member a son of Mr. Henry Laird, who is at present not of the full age required for membership. I am sure that we all sympathise with him in his recent heavy bereavement, and hope that he will one day attain to the same eminence in the Institution as have the other members of his family.

"Sir William Gray was an eminent shipbuilder at West Hartlepool, who by his enterprise and ability, attained very great success.

"Of the merits and achievements of Sir John Fowler, formerly president of the Institution of Civil Engineers, and of Sir William Anderson, formerly President of the Institution of Mechanical Engineers, I will not speak here, because their fame is of the highest, and I could not, in a few words, do justice to them.

"In Mr. Dietrich, Constructor-in-chief of the Imperial German Navy, we have lost not only a member of the highest capacity, but also one of our best friends and well-wishers. As your President during the delightful meeting we held in Germany, I know, perhaps better than most, how hard he worked to organise all the arrangements for our reception at Berlin. You, yourselves, are the best judges of the success which he achieved. I can only add with the sincerest regret that the Institution is distinctly the poorer for the loss of all these illustrious men.

"The Institution has lately lost another sincere friend, who though not one of our honorary members, always, when occasion arose, did his utmost to encourage us and to show us kindness and hospitality. I allude to M. Félix Faure, till lately the distinguished President of the French Republic. It was recently my sad duty to send a respectful letter of sympathy on your behalf to the French Ambassador condoling with His Excellency and his Government on the painfully sudden death of the Chief of their State. The late President, as I need hardly remind you, received the Institution with every honour when we visited Paris in 1895, and only last summer he sent to the Council a very kind message stating that he had not forgotten the pleasure which our visit had caused him, and that we had his best wishes for our future prosperity.

"Although the late Prince Alfred of Saxe-Coburg was not one of our members, we cannot forget that his father, H.R.H. the Duke of Saxe-Coburg, has for a long time been one of our vice-presidents, and that he lent us the most valuable support at the time of our International Congress. I am certain that I express the feelings of the whole Institution when I say that we deeply deplore the loss which has overtaken His Royal Highness and his house in the death of his only son.

"I will now turn to matters of a less painful nature. You have all heard from the Report of Council of the very friendly invitation which we have just received from the Mayor and Corporation of Newcastle-on-Tyne and the President and Council of the North-East Coast Institution of Engineers and Shipbuilders. You are no strangers to Tyne-side hospitality, for, twelve years ago, you paid a memorable visit to the city of Newcastle. In accepting the invitation which has been so warmly given, the Council feel certain that they will meet with your strong support in making the meeting a great success. Considering all that there is to see in the city and district, our visit cannot fail to be both interesting and instructive.

"The shipbuilding world during the past year has been in a state of intense activity, and this remark applies no less to the Royal Navy than to the Mercantile Marine. I feel, and I have much pleasure in doing so, that I may congratulate all who are engaged in the industry upon a state of unexampled prosperity.

"In my opening address last year I ventured to prophesy that everything pointed to there being shortly a great and continued revival in business, which would in some degree repair the losses suffered, both by employers and employed, through the deplorable labour dispute of 1897. This anticipation has been very fully realised. Both as regards work done and orders in hand, the year which has elapsed since our last meeting has been one of remarkable expansion in the shipbuilding industry, and this expansion bears striking testimony to the elasticity of our industries connected with marine construction. A very few figures will justify my contention.

"The output of tonnage of the United Kingdom in 1898 surpassed all previous records. The mercantile tonnage launched amounted to 1,367,000 tons—a total which exceeded that of 1897 by no less than 44 per cent. In addition to the above, warships with a total displacement of 196,000 tons were launched, and of this amount it may be interesting to note that more than three-fifths were built in private yards. These figures, taken together, exceed those of 1897 by 100 per cent.

"If we turn to orders in hand, the condition of things is equally satisfactory. The returns which I quoted last spring showed that the work then in hand amounted to no less than 1,023,000 tons—a condition of things, at the time, without precedent in the shipbuilding industry of the country, but which is at the present juncture entirely surpassed. The new mercantile shipping actually in progress, according to the latest statistics, reaches the huge total of 1,400,000 tons, showing an increase of nearly 40 per cent. over the corresponding figures of a year ago. In addition to this, there is now a vast number of warships under construction, amounting to a displacement of 410,000 tons, of which considerably more than half is being built in private yards. It is, moreover, generally understood that orders for new tonnage are still sufficiently numerous to give every prospect of full employment to our building yards for some time to come.

"Little commercial experience is needed to infer from figures like these that prices in all trades connected with shipbuilding must have been and are eminently satisfactory, at any rate from our point of view. The enormous pressure of work must have tended to stop that severity of competition which produces low, and perhaps unremunerative, rates. It is this abnormal demand for shipbuilding material which accounts for those instances in which American tenders for steel plates intended for vessels to be built in this country have been accepted, concerning which transactions alarmist articles in our newspapers are occasionally published.

"Striking testimony is borne by the figures which I have already given to the resources of our marine engine-builders, for, almost without exception, the vessels which were constructed last year, and those which are still being constructed in this country, are propelled by steam power. Less than one-third per cent. of the mercantile output of 1898 was made up of sailing tonnage, and the work now in hand consists even more completely of steamers.

"Gentlemen, we all know that this Institution is somewhat international in its character, and I may now congratulate our foreign members upon the fact that the revival in shipbuilding is by no means confined to one country. All our neighbours are feeling the benefit of it.

"The vanishing of the sailing vessel from the shipbuilding yards of the United Kingdom leads me to remark again upon the directly opposite tendency which is observable in France. In that country, fostered by certain provisions of the Bounty Laws, the construction of large steel sailing vessels is making rapid progress, while no proportionate expansion has taken place in the building of steamers. During 1898, the sailing tonnage launched by French shipbuilders amounted to upwards of 30,000 tons, and formed 45 per cent. of the total mercantile output of the country. These figures included twelve sailing vessels of 2,000 tons and upwards. At the present moment not less than twenty-six large sailing vessels, with an aggregate of 63,000 tons, are in hand or on order. The ultimate result of building so many vessels of a kind which the ordinary requirements of commerce do not appear to demand in other countries, will be watched with interest.

"In Italy also a great development of shipbuilding is taking place. The industry in that country, as in France, is affected by Bounty Laws. But there the expansion is found exclusively in steam tonnage. Shipping to the extent of 90,000 tons is now in hand or on order in Italy. This is nearly three times as much as was the case when we met last spring.

"Last year the first place among foreign countries in total output was held by the United States, a result mainly due to the large production of vessels built for the Great Lakes. In Germany at the present time 168,000 tons are now in course of construction, including eight steamers of 10,000 tons and upwards, as compared with only four vessels of such a size in hand in this country.

"Before I leave the subject of the Mercantile Marine, I must congratulate Messrs. Harland & Wolff upon the successful launch of that magnificent ship the *Oceanic*, the largest vessel now in existence, and having a greater length than any which has ever been built. Last year, in this place, I pointed out that our German friends had constructed the largest ships in 1897. Our good friend, Mr. Laeisz, of Hamburg, commenting subsequently on what I had said, wittily remarked, 'It is true that Britannia has this year waived the rule, but next year she will, no doubt, continue to rule the waves.' That prophecy has turned out to be true, and to our friends Mr. Ismay and Mr. Pirrie and to their colleagues must be given the credit of having fulfilled it. The *Oceanic* has been described so fully in the newspapers that I will not now refer to her details; but I may be allowed to express the hope that, after she has completed her trials, we may hear something more about her at this Institution.

"The figures which I have given above amply prove that the leading commercial nations of the world are largely increasing their mercantile fleets, in order to cope with the ever-growing demands of an expanding commerce. The majority of these nations, our own country included, are also adding extensively to the war navies upon which their commerce must ultimately rely for protection.

"If we glance at the list of ships built, or which were building, during the past year, for the Royal Navy, we must certainly admit that our Admiralty is alive to the great responsibilities which rest upon it, and is fully determined to meet them. The cost of these increased armaments is undoubtedly heavy; but no prudent citizen will grudge an expenditure which, after all, only amounts to a very moderate insurance on that vast seaborne trade which is the very lifeblood of our existence.

"With the wider questions of Admiralty policy we have nothing to do at this Institution, but all matters which relate to the nature of the ships being built for the Navy are necessarily of great interest to us. During the past year progress has been made upon sixteen new first-class battleships and seventeen first-class cruisers, exclusive of two which, though sanctioned, have not yet been commenced. In addition to the above there are now completing, or building, four second-class and seven third-class cruisers, besides vessels of smaller denominations, such as sloops, gunboats, and torpedo-boat destroyers. The battleships belong to three different groups. There are six of the *Canopus* class, six *Formidables*, which are an improved type of the *Majestic* class, and, lastly, the four ships of the supplementary programme which was sanctioned at the end of last Session and partially put in hand at the commencement of the present year. The four latter ships are intermediate in size between the *Formidable* and *Canopus* classes. They will have practically the same armament as the *Formidables*, but thinner armour. The vertical side armour is to be seven inches thick over a considerable portion of the body of the ship, tapering to the bow. The barbettes will have 11 in. and the casemates 6 in. armour, all of the latest and best quality. The speed at natural draught will be nineteen knots, which is greater than that of any of our other battleships. The following are the principal dimensions:—Length between perpendiculars, 405 ft.; breadth, extreme, 75 ft. 6 in.; mean draught, 26 ft. 6 in.; displacement, 14,000 tons.; power, 18,000 I.H.P.

"Of these sixteen ships seven are being built in private yards. All of them embody the latest improvements in design, armour, armament, and machinery. They are being built in homogeneous groups, each group capable of acting as an independent fleet, thus carrying out a policy which the Admiralty have adopted for some time past, and upon which they are entitled to the highest praise.

"The first-class cruisers actually in hand, or completed during the year, are also divided into three types. We have, first, seven out of the eight protected vessels of the *Andromeda* and *Diadem* classes of 11,000 tons displacement; then six armoured cruisers of the *Cressy* type of 12,000 tons, to which I alluded in my address last year; and four new ships of the *Drake* class, which are described as being armoured *Powerfuls*, 500 ft. long, 14,100 tons displacement, and having machinery capable of exerting 30,000 H.P. with estimated speed of 23 knots on trial. The main armament will be two 9·2 in. guns of improved type with armoured shields, and sixteen 6 in. quick-fire guns in casemates. The vertical side armour will be six inches thick over the main body of the ship, with armoured decks. The hulls will not be sheathed. The total bunker capacity will be 2,500 tons, and half this quantity will be carried on the speed trials.

"Nothing connected with the development of the Fleet is more remarkable than the extraordinary growth in the size of cruisers. The displacement of individual vessels has gone up by leaps and bounds from the time when the vessels of the *Edgar* class excited universal admiration. The largest cruisers of that date varied from 7,350 to 7,700 tons displacement, and 12,000 H.P., while each of the four cruisers above referred to has a displacement nearly double that of the *Edgar* and slightly exceeding that of the latest type of first-class battleships. The demand for increased speed, greater radius of action, and improved protection mainly accounts for this great growth in displacement.

"The two new cruisers, belonging to the special programme, which have not yet been commenced will be of more moderate dimensions. They will be 440 ft. long. of 9,800 tons displacement, 22,000 I.H.P., and their estimated speed at natural draught is 23 knots. Their armament will consist of fourteen 6-in. quick-fire guns, of which four will be in pairs in turrets and ten in casemates, the armour in each case being 4 in. thick. The vertical side armour over a considerable portion of the body of the ship will be of the same thickness, with thinner protection on the bows. There will be strong protective decks associated with the vertical armour, and the hulls will not be sheathed. The bunker capacity will be for 1,600 tons.

"The programme for the coming year embraces two first-class battleships, the design of which has not yet been settled, two armoured cruisers of 9,800 tons, three lesser cruisers, and sundry smaller vessels.

"I feel that I cannot dismiss this subject without saying a few words upon the vast amount of work and responsibility which the reconstruction of the Fleet, commenced on the passing of the Naval Defence Act in 1889, has entailed upon the Department of the Controller of the Navy. I don't suppose that the officials at the head of the Constructive and the Engineering Departments at the Admiralty have ever enjoyed sinecures; certainly they have not done so during the forty years which constitute the lifetime of this Institution; but, in the ten years which have elapsed since the framing of Lord George Hamilton's programme, it seems to me that work of a particularly onerous and responsible character has had to be performed. The outside public are, perhaps, apt to ignore all that is involved in carrying out a great programme of construction. They think that, when the money is voted and the building of the ships sanctioned, everything is done. They read with complacency that the country possesses so many ships — built, building, or projected—but they know little, or nothing, of the responsibilities and labours of those who have to settle what shall be the offensive and defensive powers, the speed, and the coal endurance of the ships, and of those who have to realise these qualities in the ultimate designs sent to the building yards. Equally little do they know of the splendid organisation and mechanical resources of the dockyards and of the great private building firms, an organisation which has recently resulted in a first-class battleship being launched within eight months of its commencement. Perhaps the cost of the work done may enable the public to appreciate to a certain extent the labours of those who serve them. For the ten years ending March 31st, 1898, the average annual expenditure on new ships, machinery, and gun-mountings has amounted to about four and a half millions sterling, which is, roughly, double the annual average outlay in the decade preceding the reconstruction of the Fleet. During the four years ending March 31st, 1898, the average expenditure has been £5,600,000 per annum, while in one year, 1896-97, as much as £7,327,000 was spent, and in the year upon which we are about to enter the cost of new work will nearly reach £9,000,000, a figure which is absolutely without precedent.

"When I consider the enormous importance to this country of its Navy and of its Mercantile Marine, and when I consider that both marines have been practically reconstructed within the last dozen years, and when I further reflect on the part which our members have played in effecting this reconstruction and in developing the inventions which have done so much towards perfecting the art of steam navigation, I cannot but think that this Institution of ours is playing a large part in the life of our country, and that no prouder position could fall to the lot of any man than to preside over its destinies. It is, therefore, peculiarly gratifying to me to feel that the duties which Her Majesty has been graciously pleased recently to confide to my care do not necessitate my severing my connection with you. I am grateful to the Council for the kindly reference which they have made regarding me personally in their Report, and I would assure you that I shall continue, to the best of my ability, to promote the interests and welfare of the Institution. I now beg to thank you for the patience with which you have heard me, and to move the adoption of the Report."

STEAM PIPES.*

By J. T. Milton, Esq., Member of Council, Chief Engineer Surveyor of Lloyd's Register of Shipping.

In 1895 the author had the honour of reading a paper on steam pipes before the members of this Institution, and it is thought that some further remarks upon the subject would not be out of place in view of its increasing importance. When it is remembered that there are in existence about 15,000 steam vessels of above 100 tons register, and that in any vessel the failure of a steam pipe may possibly lead to her total disablement, and that every day sees several additions to the number of vessels in which steam pipes of larger size and working at higher pressure are used, it will be realised that the subject is one which demands the attention and consideration of Marine Engineers.

When dealing with matters in general use, or coming under common observation, there is no doubt that a few failures teach their lessons more emphatically than a large number of successes, and, therefore, in this paper reference will be made to some of those cases of accidents to steam pipes which have been publicly inquired into under the provisions of the Boiler Explosions Acts of 1882 and 1890. A summary of all the cases which have been so inquired into is given in the Appendix to this paper, but it must not be thought that these are all the serious accidents to steam pipes which have happened, as many failures occur which are repaired without the facts becoming known to the officials whose business it is to hold these inquiries.

It will be seen from the Appendix that in none of the cases has failure occurred through original weakness of the pipes themselves, that is to say, through their being originally made too thin. In the majority of cases the troubles have arisen through the design of the pipes having been at fault. In fourteen out of the sixty-eight cases referred to, the accident occurred through there being no provision for draining the collection of condensed water from the pipes; while in no less than thirty-eight, or more than half of the total accidents, there was insufficient provision for expansion and contraction, and for the motion due to vibration, &c., and in many of these cases similar accidents had previously occurred without being inquired into. In a few cases the explosions occurred either through original defective workmanship or through defects which subsequently developed in the pipes.

It will be well to first consider the materials used for pipes before dealing with the question of design, as the latter has to be made to suit the materials employed.

The materials in general use for main steam pipes are copper, used either in the form of seamless or of brazed tubes; wrought iron, generally lap-welded; steel, also lap-welded, and sometimes fitted in addition with a rivetted butt strap covering the welded joint; cast-iron has been employed in a few cases, as also has seamless steel. Small steam pipes for auxiliary purposes are almost invariably made of copper. In a few cases, however, they have been made with seamless steel.

Of these materials copper is by far the most common. Formerly nearly all copper pipes were made from sheet copper, with brazed lap joints; straight pipes, except in the largest sizes, being made with one seam. Bends of small pipes are generally made from straight tubes; large bends, however, are made from two sheets, worked into shape by the coppersmith, and brazed along two seams. Recently improvements in manufacture have enabled seamless tubes to be made at reasonable prices, so that, up to about 6 or 7 in. diameter, most steam pipes are now made from seamless tubes, which are bent by the coppersmith into the shapes required. Generally the flanges are brazed on the pipes, but in a few cases special patent flanges are adopted, enabling brazing to be dispensed with.

That want of confidence is felt in copper pipes by the Admiralty and by some engineers is shown by their wrapping them with copper wire, or by steel wire rope, or by fitting wrought iron bands at short distances apart along their whole length.

Copper probably owes its present extended use mainly to custom, and its first selection was, no doubt, due to its non-liability to corrosion and to its great ductility. The latter, however, is a variable quantity, depending largely upon the treatment to which it has been subjected, and depending also upon its composition.

---

*[Read at the Fortieth Session of the Institution of Naval Architects March 23rd, 1899.]

When copper has been thoroughly annealed, it is very soft, and a very low stress, say, even less than two tons per square inch, will produce a slight permanent set. As the stress increases the deformation increases more rapidly, and at a tensile stress of from 13 to 14 tons per square inch, calculated from the original section, fracture will take place. In the case of good copper, which has been previously properly annealed, the elongation in 8 in. will be about 30 to 40 per cent. If the copper is stressed to any less amount than its ultimate strength, and the load released, it will be found that the stress has *hardened* the copper, and that the metal will then be practically elastic up to nearly its original load, less stress than this producing no further permanent elongation. If after this hardening the copper is again annealed, it will behave as it did in its original annealed state, a low stress again producing a permanent elongation.

The effect of hardening upon the extension, and the apparent ultimate strength of copper, is well illustrated by the accompanying autographic diagrams of tests made by Professor W. C. Unwin on specimens of copper, one being annealed and the other fairly hard. Fig. 1 represents the tests on the annealed, and Fig. 2 upon the other specimen. In these figures vertical distances represent the total load upon the specimens, and horizontal distances represent upon a scale of twice the full size the elongation in an original length of 8 in.

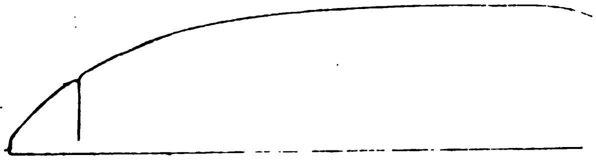


FIG. 1

The particulars of the actual tests are given in the table below.

The nearly vertical line at the commencement of each curve shows that the elasticity of the material was at first nearly or quite perfect, the falling away of the curve from the vertical portion shows the elongation which takes place after the elastic limit is passed. In the case of the hard copper, it appears that after the material has commenced to stretch, the application of the same load continues to elongate it. In the case of the soft specimen a low stress commences to stretch it, but until nearly half of the total elongation is reached, each successive increment of stretch requires a higher stress to produce it.

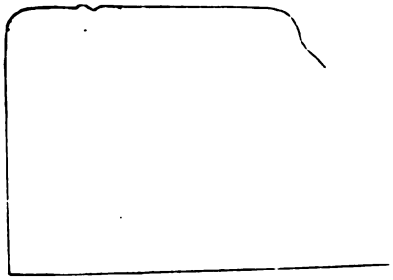

FIG. 2.

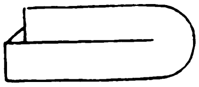
The break in the curve was produced by relieving the stress after an extension of one-third of an inch. On the load being re-applied, it will be seen that the elastic limit had been raised by the previous testing from 1·769 to 6·9 tons per square inch.

Dimensions.		Section.	Stress at Elastic Limit.	Maxm. Stress in Tons.	Elongation in 8 in.	Rem'rks
Width.	Thick.					
In.	In.	Sq. in.	Tons per sq. in.	Per sq. in.	Per cent.	
1·503	0·188	0·2826	1·769	13·03	48·13	Anneal'd
1·498	0·193	0·2891	15·56	16·13	17·88	Hard.

The lower ultimate strength shown by the annealed piece of copper is due to the stress being calculated from the original area, the great extension of the soft specimen causing more contraction of area than occurs with the harder specimen. If the stress actually borne by the two pieces is referred to the actual reduced section at the moment when each is withstanding the maximum load, it will be found that the results are approximately equal in these two cases. This shows the importance, when testing copper for the purpose of ascertaining its quality, of being careful that the specimen is properly annealed before the test.

Hardening of copper may be produced in other ways than by direct tension. Copper wire is hardened by continual bending and straightening; sheet copper is hardened by hammering or by cold rolling; pipes may be hardened by planishing or by being hammered or bent whilst they are "loaded," and copper tubes are always hardened when they are drawn on a drawbench either to a smaller diameter or to a thinner gauge. In whatever way copper is hardened its ductility is correspondingly lessened, and in all cases the hardening may be removed by "annealing," that is by raising it to a bright red heat, and either quenching it in water, or allowing it to cool gradually.

Commercial copper, as used for other than electrical purposes, is rarely pure, or even nearly pure. The effects of some of the common impurities, such as arsenic, nickel, and silver, are supposed not to be detrimental; while, on the other hand, antimony is objectionable, and bismuth, even in small traces, is exceedingly prejudicial. The usual workshop test for the quality of copper is to cut off a portion of the pipe or sheet and anneal it when it should stand bending quite close, thus, without a sign of cracking. The edges also should stand thinning to a knife-edge without crack when hammered to a scarf joint form with a lap of about three or four times the thickness of the copper.



Brazing solder is composed of copper and zinc, in about equal proportions; occasionally, however, ½ per cent. of tin is added to the mixture. The mixed metal is first cast in iron ingot moulds, then it is reheated to a certain temperature, considerably below red heat, at which it becomes brittle, and is pounded up with an iron pestle and mortar. The addition of the small quantity of tin is said to facilitate the pounding. It thus appears that at a temperature intermediate between that of the steam and a red heat, the solder becomes brittle, and unfit to sustain any stress.

It is usually considered that the brazing solder, like copper, is not liable to corrosion, and in the majority of cases in which brazed copper steam pipes have been cut up after many years of service, the brazing is found to be in as good condition as the copper. In a few cases, however, the brazing of copper steam pipes has been found to have deteriorated in use to an alarming extent. Attention was first drawn to this in the case of the fatal explosion of the steam pipe of the s.s. *Prodano*, referred to in the Appendix as No. 1,033. After the official inquiry into the matter, this case was investigated by Professor Arnold, of Sheffield, whose report was published in *Engineering*, Vol. LXV. p. 468, and *The Engineer*, Vol. LXXXV. p. 363. Professor Arnold showed that the brazing in this and in another case submitted to him at the same time had deteriorated by the whole of the zinc in some parts of the solder becoming oxydised, the copper remaining in the form of a spongy metallic mass, the pores of which were filled with the oxydised zinc. He attributed this result to electrolytic action set up by fatty acids produced in the boiler or in the steam pipe from the decomposition of organic oils, as he found and separated these organic acids from the deteriorated solder. Since attention was drawn to these cases, a few other steam pipes have been found to have been similarly depreciated in their brazing.

It is worthy of note that experience with Muntz metal exposed to the corrosive action of sea water shows that a somewhat similar deterioration of the zinc takes place. It is said that this is prevented if a small quantity of tin is added to the mixture; but in the cases of the brazing solder investigated by Professor Arnold, one specimen which originally contained ½ per cent. of tin was equally affected to that composed of copper and zinc only.

The properties of wrought iron, mild steel, and cast iron are too well known to require lengthened description. In making either wrought iron or mild steel welded steam pipes, the tubes are made from rolled strips or plates, the edges of which are bevelled by machine, and the weld is always lap, not butt. In all but the largest sizes the welding is done in rolls at one heat the whole length, but in the largest sizes of pipes it is done piece by piece in a similar way to the welding of boiler furnaces. In wrought iron a free welding quality is usually selected in preference to a very strong iron, soundness of weld being considered to be of the first importance. In mild steel the very mildest qualities are selected for the same reason. With either material the requirements of manufacture, except in the cases of the very largest pipes, are such that the thickness is in excess of the requirements of strength for such steam pressures as are now in use, so that when iron or steel pipes are used a very large margin of strength is always provided.

In the case of wrought iron pipes it is usual to trust to the welded joint, but in the case of mild steel, in some cases a rivetted butt strap has been fitted as an extra precaution over the welded joint. Experience, however, with steel lap-welded boiler and other tubes has shown that, with the mild qualities of material actually used, as reliable welds can be made with steel as with wrought iron. It need hardly be pointed out that butt straps add considerably to the weight and cost, and that every needless rivet hole is a possible source of leakage and trouble, so that if the welds are really efficient, and if they could be tested so as to practically eliminate the probability of defective workmanship, butt straps would soon be dispensed with.

To put such a high hydraulic test upon welded steel as would really stress the material to nearly its elastic strength is impossible, except with the largest pipes, owing to the thickness adopted being much greater than is needed from the requirements of strength alone, and the fact that such pressures would strain the flanges and flange fastenings, but tests of three or four times the working pressure can always be made. It has been suggested by some pipe makers that, to give confidence in the welds, each steel pipe should be made somewhat longer than is actually required, and that test pieces should be cut off from one or both the ends before flanging and opened out and tested in a testing machine across the weld. In addition, of course, a high hydraulic test would be made after the flanges are fitted.

Flanges for wrought iron or steel pipes may be welded to the pipes, but usually they are screwed on. In some cases they have been rivetted to the pipes. Successful plans are shown in Fig. 3, in which the flanges have been forged out of the solid, without weld, and screwed on the pipe with a diminishing thread. The thread extends through the whole thickness of flange, but in more recent practice the flange overlaps a part of the pipe without thread. In either case the flanges are caulked on both sides to ensure steam tightness.

When wrought iron or steel pipes are used, the designs are generally made so that individual pipes are straight or nearly so. It may be of interest, however, to know that if bent pipes are really required they can be made with a radius of three times the bore for pipes below 6 in. diameter, and four times the bore for pipes up to 12 in.

In the paper of 1895 it was stated that cast iron steam pipes had been used with success for many years, and a list was given of several vessels in which such pipes were fitted, and the periods during which they were in use were also recorded. In most of these vessels the cast iron pipes are still in service. The almost invariable use of cast iron for stop valve chests, &c., shows that as a material it can be relied upon for strength and durability, and the experiences with the vessels referred to show that pipe designs can be made permitting the use of rigid material.

When wrought iron or steel pipes have been used for modern vessels, experience has shown them to be admirably adapted for their purpose, and no trouble whatever has been experienced with regard to their corrosion.

Having now discussed the qualities of the different materials used for steam pipes, it will be well to refer to the conditions which the pipes have to fulfil in actual use.

The first condition to be noticed is that the pipes have to be

THE NEW
PUBLIC LIB
ASTOR, LENOX
TILDEN FOUNDA

Fig. 3

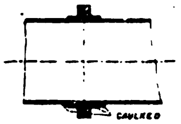


Fig. 4

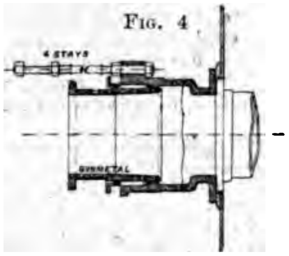

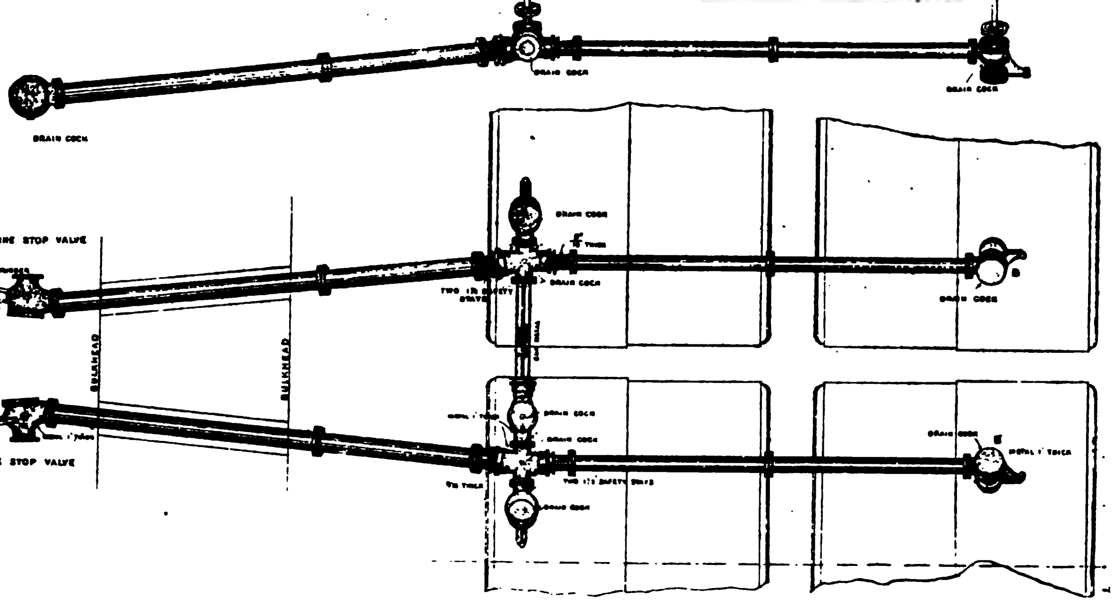

Fig. 6.

strong enough to withstand the pressure to which they are to be subjected. In the case of wrought iron or steel, as has already been stated, conditions of manufacture require such a thickness that the strength is more than ample. Copper pipes, however, may easily be made of less strength than sufficient. The usual practice of marine engineers is to take the Board of Trade Rule as a minimum. The rule is as follows:—

Thickness in inches

$$= \frac{P \times D}{6{,}000} + \frac{1}{16} \text{ in.}$$

for brazed pipes, and for seamless pipes not over 8 in. wide

$$= \frac{P \times D}{6{,}000} + \frac{1}{32} \text{ in.}$$

P being the working pressure in lbs. per square inch, and D the inside diameter in inches.

When making copper pipe, either from sheet or from straight lengths of tube, it is usual to make the bends from material one gauge thicker than would be used for straight lengths, and if the bends are very severe, to use two gauges thicker. This is necessary, as the material at the back of the bends is thinned in working. It must not be lost sight of that the extra thickness remains over the greater portion of the pipe, which is therefore rendered more rigid than it would be if it were uniformly of the minimum thickness.

Regarding questions of strength only, it is well known that, in cylinders subjected to internal pressure, the circumferential stress produced in the material is double that in a longitudinal direction. A pipe under hydraulic pressure will therefore always yield first by bursting open along the line of least strength, usually the seam. A reference to the failures which have actually occurred in practice, however, as given in the Appendix, shows that most of the fractures occur circumferentially at or near the flanges, and are obviously due to longitudinal stresses. The causes of these must therefore be looked for from other than internal pressure.

The next condition to be noted is that when in use the pipes will be much hotter than when they are fitted up, or when not in use. The temperature of steam at 200 lbs. pressure—a common pressure now—is 388° F. At 300 lbs., at which some boilers are being worked, the temperature is 422°, so that when in use the temperature of the pipes may be from 350° to 390°, or even more in excess of that at which they are fitted up. The coefficient of expansion of iron or mild steel for a range of 360° is ·0024, and that of copper is ·0037. Pipes, therefore, of these materials will tend to become longer when in use by these amounts. In addition to this the boiler itself, to which one end of the length of pipe is attached, also expands, and thus raises one end of the pipe from 3/16 in. to ½ in., according to the size of the boiler, while the end attached to the engine remains stationary. The necessary alteration of form of the pipes to allow for these expansions must be provided for in the design of the steam pipes, either by providing properly constructed expansion joints, which will allow the requisite freedom of motion, or by making the pipes of such form that the movements can take place, owing to the ductility of the material, without producing undue stresses on the pipes themselves, or on their connections to the stop valves and engines.

When cast iron or wrought iron pipes are employed, it is usual to consider that their rigidity is too great to allow of the expansion to be accommodated by the flexibility of the pipes themselves, and generally, therefore, expansion joints are fitted to them. An example of such a joint is shown in detail in Fig. 4.

With copper pipes, however, it is more often considered that the pipes will be sufficiently flexible, and the material sufficiently ductile, to permit of their repeated contraction and expansion without the need of stuffing-box expansion joints and consequently these are rarely fitted. Undoubtedly pipes can be made sufficiently flexible to meet all practical requirements; but, unfortunately, many of the designs in general use, sometimes combined with the faulty workmanship of not properly annealing the pipes, are such as to give continued trouble in keeping the flange joints tight and in some instances also in producing rupture of the pipes at or near the flanges. Some of these designs will be presently referred to.

It must be borne in mind that the hollow cylindrical form is one naturally possessing great strength and rigidity in proportion to its weight, and hence its general use for columns, &c., *where stiffness is required.* This property is often forgotten *when dealing with pipes, and they are often credited* with far more flexibility than they possess. In questions dealing with the rigidity or flexibility of pipes, it is well to remember that if a solid bar and a hollow tube of the same material, and the same length and shape, are subjected to the same loading, producing either traverse bending or torsion, or the two combined, the deflections will be identical if the diameter of the solid bar be equal to

$$\sqrt[4]{D^4 - d^4},$$

where D and *d* are the outside and inside diameter of the pipe. A bar of this diameter may therefore be looked upon as the equivalent of the tube when considering its flexibility, and if such a bar be flanged at the ends like the pipe, and attached to the stop valves, &c., by the flanges, the strains which the expansion, &c., will put upon the flanges of the stop valves will be the same by the bar or by the tube.

Let us now consider a pipe such as is commonly employed, say, such as fitted in one of the cases referred to in the Appendix. This pipe forms a right-angled bend, the two arms being 2 ft. and 6 ft. long respectively, the inside diameter of the pipe is 6 in., and its thickness is ·212, so that its stiffness or rigidity is equal to that of a solid bar of copper 4⅛ in. diameter. The expansion due to its temperature would, if not resisted, increase the lengths of the two arms by over 1/12 in. and ¼ in. respectively, and in addition one end is raised up by the expansion of the boiler about ½ in. The pipe therefore has to have such forces applied to the flanges at the two ends as would bend a solid bar 4⅛ in. diameter till the arms were shortened by the amounts mentioned, as well as displace one end ½ in. vertically, and at the same time there must be such bending moments applied to the ends as will keep the flanges in the same plane. These forces have to be borne by the thin metal of the copper pipe at the parts where it is brazed to the flanges. If a larger pipe were considered the forces involved would be even greater in proportion. If the copper is at first well annealed, these forces, being more than sufficient to produce stresses beyond the limits of elasticity, will doubtless permanently alter the shape of the pipe. At the parts where deformation takes place the copper will be somewhat hardened. When the pipe is cooled down it will tend to regain its original shape and length, and strains will be set up in it of opposite character to those caused by heating it. Each raising and lowering of steam will therefore bring alternating stresses on the pipe, each time tending to harden the material and decrease its ductility at those parts where most deformation takes place. There is no wonder, therefore, that in time the whole of the ductility is destroyed, and the pipe cracks round near one or both flanges.

From the diagrams shown in Figs. 1 and 2 it will be evident that, while on the one hand the more thoroughly annealed the material of the pipe is the more easily it will be deformed, yet, on the other hand, when well annealed the yielding power or ductility of the copper is such that very considerable deformation can take place without danger. Fig. 2, however, shows that with hard copper very much less yield can take place without the production of great strains, and consequently of great risk.

It may be well to point out that the expansion of iron is only about two-thirds of that of copper, so that the deformation in an iron pipe would be only two-thirds of that of a copper pipe; but, on the other hand, it is a stronger material, and in general, iron pipes would be thicker than those of copper, so that with iron there is considerably less flexibility than with copper.

When copper pipes have to take up the expansion and contraction by their alteration of form, it cannot be too strongly urged that they should be annealed uniformly throughout their whole length. Unfortunately the practice on this point is not well established. Some coppersmiths are particular in seeing that this is done; generally, however, only the bends, that is the parts where the pipes have been bent and therefore extra hardened, are annealed, the straight portions being left unannealed, whilst other coppersmiths leave even the bends unannealed. The portions near the flanges always become annealed when the flanges are brazed on, and unless the pipes are afterwards annealed their whole length it happens that the whole of the deformation strains become concentrated upon the soft part at the flanges where there is the greatest tendency for rupture to be produced.

From what has been stated, it would appear to be desirable that copper pipes, which have to take up expansion deformations, should be periodically annealed. This, however, brings up the question as to how the annealing of a bent pipe can be effected. The workshop practice is at best a makeshift one, the usual, and practically the only plan, being to heat successive portions of the pipe over an open coke fire, the workman turning it round and shifting it about over the fire until each part in turn is thought to have been raised to a red heat. Irrespective of the difficulty of getting the inner side of a large bend near the coke fire, this method leaves much to be desired, and involves a great risk of some parts being left hard, while the remainder is annealed. An unhomogeneous pipe may be in a worse condition than one wholly unannealed, and hence the reluctance of marine engineers generally to have pipes which have been satisfactorily at work for some time taken down and possibly injured in the attempt to anneal them. It is not too much to ask that our engineers should, if they will continue to use large and thick copper pipes, provide proper furnaces where the pipes may be uniformly heated throughout their whole length at one operation.

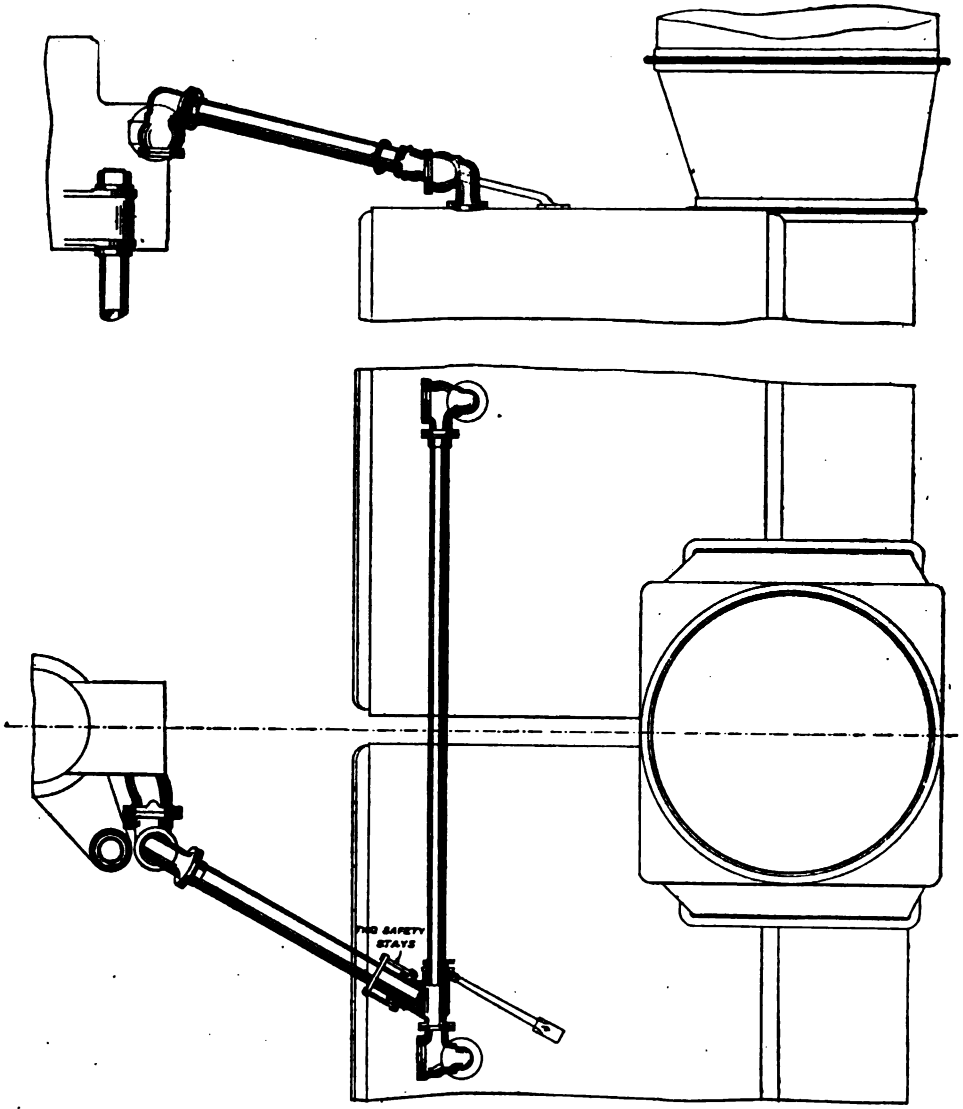

Fig. 5.

There is, however, no absolute necessity in most cases for using bent pipes. Straight pipes can nearly always be designed to meet all requirements, and the expansion of these can be provided for by expansion joints of the form shown in Fig. 4. These joints are, it is true, objected to by some engineers as being likely to be a continual source of trouble, but that this is not a correct view is shown by the fact that in our very largest mail boats they have been fitted and found to present no great difficulty in keeping them in order, while one of the largest engineering firms on the East Coast have practically used no other design for very many years for their main steam pipes, and their engines and arrangements are at least as popular as those of any of their competitors. Further, it must be remembered that, even if some trouble is experienced in keeping stuffing boxes in order, serious troubles with leaky joints are by no means unknown, where the expansion has to be met by straining the pipes themselves. Figs. 5, 6, and 7 represent plans which have been successfully adopted for steam pipes in which all the pipes are practically straight and the expansion provided for by expansion joints.

In providing for the expansion to be taken up by expansion joints, it is necessary to ensure that the lengthening of the pipe shall really take place by pushing into the joint meant to receive it, and that on the contrary the end of the pipe shall neither be stationary in the joint nor drawn out of it. This can only be ensured by making arrangements for fixing the expansion joint in position, and also securing the other end of the pipe to a fixed position, either by means of long stays attached to the expansion joint itself or by some other means.

The blowing out of the pipe by the steam pressure may possibly take place if there is a large bend in the pipe, as is seen in some designs. In such cases the preventive fastening should be secured to the bend, not to the pipe near its free end. Expansion joints are often fitted with what are called safety stays to prevent the pipe being blown out. When these are short and fitted too near the free end of the pipe they are either useless, or the expansion joint itself is useless, as they cannot come into service if the pipe expands into the joint as it is intended to do. They may moreover be an absolute source of danger, and at least one of the failures of steam pipes recorded in the Appendix was due to their being fitted. When steam is up and the pipe expanded the safety flange should be some distance off the nuts of the stays. If in this condition the nuts are thoughtlessly or ignorantly screwed up to the flange, on the pipes cooling down and contracting they will be subjected to great strains, and something must fracture to relieve them. If such stays are fitted, therefore, the nuts on them should be carefully adjusted when cold and be *fixed* in place, either by pins through them, or by ferrules placed over the stays of such a length that the nuts cannot be screwed down too far. Properly designed pipes, however, will not need these stays at all. In none of the plans shown in Figs. 5, 6, or 7 are these stays really required, although they have been fitted.

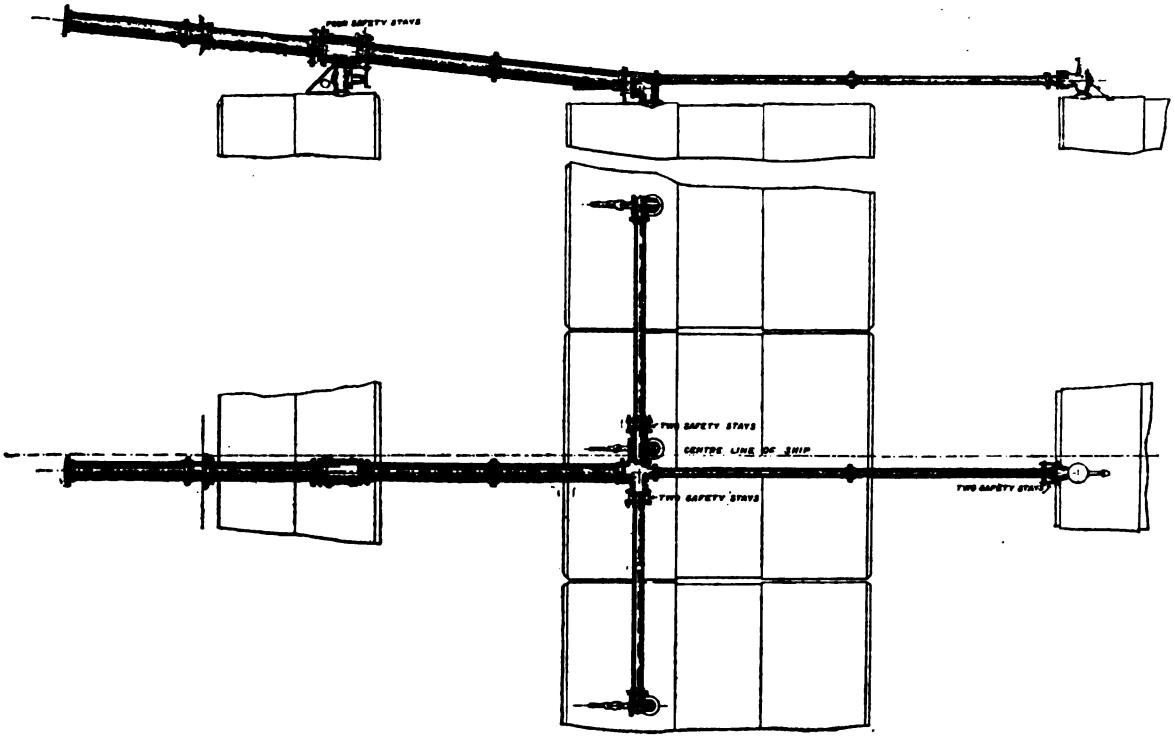

FIG. 7

Whilst referring to the expansion of pipes it will be well to call attention to the methods of supporting long lengths of pipe. These should be so arranged that while giving the necessary support and preventing vibration, they will not of themselves prevent the movement of the pipes due to their expansion and that of the boilers. If this is not provided for, the supports may possibly put much greater stresses on the pipes than would result from their being left altogether unsupported. Unfortunately, this point is often neglected by the designer, the hangers being arranged on the vessel by the mechanics, who fit them in place, who may not fully appreciate all their requirements.

The remaining point, as regards pipe design, is the necessity of providing for means of freeing the pipes from water which may accumulate in them. In installations where there is more *than one* boiler it may at any time happen that for some reason *steam is not raised in all the boilers* at once; the pipes connected to those boilers not in use may form not only condensers, but also convenient receptacles for the water condensed from leakage into them from the stop valves of the boilers under steam. Provision should always be made for draining any part of the pipes where water can accumulate, and too great care cannot be taken, when opening stop valves, to connect a boiler with others already in use, to ensure that there is no water in any of the pipes. Fourteen of the explosions referred to in the Appendix were thought to have been caused by want of attention to these points.

It is hoped that this paper will call special attention to the design of steam pipes, and elicit the opinions of our experienced engineers, with a view of improvements being effected, so that such casualties as have been referred to may in the future be less frequently met with.

APPENDIX.

LIST OF CASES OF CASUALTIES TO STEAM PIPES, &C., INQUIRED INTO UNDER THE PROVISIONS OF THE BOILER EXPLOSIONS ACTS OF 1882 AND 1890.

No. of Inquiry.	Name of Vessel.	Date.	Remarks.
120	S.S. Simoom	1885	Explosion of copper bellows expansion joint, which was constructively weak.
169	Ranger	1886	Cast-iron pipe, 6¼ in. diameter, decayed where it passed through the up-take, and was exposed to heat. Pipe was 26 years old,
238	Elbe	1887	Explosion of copper pipe, which was probably cracked in the process of manufacture.
277	Erin	1888	Wrought-iron pipe connecting top of water gauge to boiler corroded. Pipe was 20 years old.
299	Bryn Glas	1888	Intermediate stop valve cover broke, attributed to the wheel for opening the valve being turned the wrong way.

389	Clyde	1890	Winch stop valve broken at flange, through insufficient provision for expansion of pipe.
453	Springbok	1890	Main steam pipe broke at flange, through want of provision for expansion. Four times previously repaired at same place.
460	Jumna	1890	Main steam pipe burst at lap; probably due to defective workmanship at original brazing.
468	Number Three	1891	5½ in. copper pipe burst at brazed joint of a bend. Brazing was thought to have been defective, and the accident was attributed to the presence of water in the pipe.
480	Greencastle	1891	Copper steam pipe broke at flange, through expansion joint fitted being useless.
512	Rohilla	1891	Copper pipe, 14 in. diameter, failed at seam. Accident attributed to presence of water in the pipe.
530	City of Lincoln	1891	Copper pipe cracked through solid copper at edge of brazed seam. Accident attributed to water in pipe, and existence of old flaws in the copper.
543	Ragusa	1892	Copper pipe, 6 in. diameter, fractured circumferentially at flange connecting it to stop valve. Four times previously repaired. Want of provision for expansion.
556	Lockmore	1892	Branch of stop valve chest broke off, through expansion joint being inefficient.
572	Shannon	1892	Copper pipe, 8 in. diameter, broke at flange; attributed to presence of water in pipes.
578	Vulcan	1892	Copper pipe, 6 in. diameter, failed at brazing of seam.
580	Grimsby	1892	Copper main steam pipe burst at part adjacent to brazed seam. Attributed to water in pipe.
584	Astrion	1892	Copper pipe burst at a junction piece. Failure attributed to insufficient provision for expansion. Pipe had been several times previously repaired.
589	Vivla	1892	Cast-iron stop valve chest burst, through accumulation of water.
657	Othello	1893	Copper pipe broke at flange, through insufficient provision for expansion.
659	Astrakhan	1893	Copper winch steam pipe broke at flange, attributed to water in pipe.
718	Urpeth	1894	Copper main steam pipe broke at flange, through inefficient provision for expansion.
728	Beresford	1894	Copper steam pipe, 4½ in. diameter broke at flange, through want of provision for expansion. There were two similar failures at short intervals
742	Raglan	1894	Copper steam pipe 7½ in. diameter, broke at flange, through insufficient provision for expansion. Had previously failed in same way, and had been repaired.
749	Iron King	1894	Copper main steam pipe broke at flange, through insufficient provision for expansion. Had previously failed in same way, and had been repaired.
767	Metal	1894	Copper main steam pipe broke at flange through insufficient provision for expansion.
772	Iron King	1894	Copper pipe, fitted five months previously, broke at flange, through insufficient provision for expansion. This new pipe had previously been three times repaired.
775	Cornhill	1894	Copper pipe broke at flange, through want of provision for expansion.
833	Seaham Harbour	1895	Copper junction piece burst. Want of proper provision for expansion. Had been previously repaired.
854	Danehill	1895	Copper main steam pipe broke at flange, through want of provision for expansion.
915	Ethel	1895	Copper main steam pipe broke at flange, through want of provision for expansion. Had previously failed, and had been repaired.
925	Scot	1895	Auxiliary steam pipe failed, through defective brazing of flange.
929	Sabrina	1895	Cast-iron stop valve chest burst, attributed to water in pipes.
930	England	1896	Cast-iron stop valve chest burst, due to corrosion; 22 years old.
933	Orient	1896	Main steam pipe failed at brazing, attributed to water in pipes.
934	Sarpedon	1896	Cast-iron stop valve chest burst, attributed to water in pipes, and possibly original defect of chest.
943	Vane Tempest	1896	Copper main steam pipe broke at flange. Insufficient provision for expansion.
945	Mobile	1896	Copper main steam pipe broke at flange. Insufficient provision for expansion.
948	Verax	1896	Copper main steam pipe broke at flange, through insufficient provision for expansion.
958	Bencliff	1896	Copper main steam pipe, 5 in. diameter, broke at flange, through insufficient provision for expansion. This pipe had been been fitted with iron bands at 8 in. intervals.
970	Pectan	1896	Copper main steam pipe broke at flange, through insufficient provision for expansion.
971	Lapland	1896	Cast-iron valve chest broke at flange connecting it to engines; 24 years old.
986	Urmston Grange	1896	Copper pipe 3½ in. diameter burst. Probably original defective workmanship.
992	Indrapura	1897	Copper main steam pipe broke at flange, through insufficient provision for expansion.
1,003	Anglia	1897	Cast-iron stop valve chest broke at flange, through collision of vessel.
1,011	Nedjed	1897	Copper steam pipe, 9½ in. diameter, broke at flange, through want of provision for expansion.
1,013	Dalmally	1897	Copper main steam pipe broke at flange, through want of provision for expansion.
1,015	Selma	1897	Copper main steam pipe broke at flange, through want of provision for expansion
1,021	Aberdare	1897	Copper main steam pipe broke at flange, through want of provision for expansion.
1,024	Birdoswald	1897	Copper pipe, 5½ in. diameter, broke at flange, through want of provision for expansion. Previously there were four similar failures in this vessel.
1,033	Prodano	1897	Main steam pipe burst, through failure of brazing of steam.
1,034	Ethelburga	1897	Small gun-metal stop valve burst, through faulty design.
1,035	Keemun	1897	Copper steam pipe broke at both flanges, due to want of provision for expansion.
1,036	Bendi	1897	Copper main steam pipe broke at flange. No provision for expansion.
1,048	Clan Macnab	1897	Cast-iron stop valve chest burst attributed to water in pipes.
1,049	Swansea	1897	Copper main steam pipe broke flange. Had previously failed same place and had been repaired. No provision for expansion.
1,056	Duchess of York	1897	Copper main steam pipe burst; attributed to water in pipes.
1,057	Thornhill	1897	Copper main steam pipe broke at flange. Had previously been renewed. Want of sufficient provision for expansion.

1,069	Eveline	1897	Three copper main steam pipes broke at flanges in this vessel at different times. No expansion joints are fitted.
1,072	Vienna	1897	Cast-iron junction chest broke at flange; attributed to water in pipes.
1,073	Suningdale	1897	Copper main steam pipe broke at flange. Two previous failures. No provision for expansion.
1,095	Burma	1898	Copper main steam pipe broke at flange; due to insufficient provision for expansion.
1,109	Amsterdam	1898	Cast-iron valve chest burst; attributed to water in pipe.
1,110	Vedra	1898	Copper main steam pipe burst at seam, which was thought to have been originally defective.
1,111	Lobelia	1898	Copper main steam pipes broke at flanges on three occasions. Insufficient provision for expansion,
1,113	Marie Roze	1898	Copper main steam pipe broke at flange; attributed to expansion joint being inoperative.
1,119	Eastry	1898	Copper main steam pipe broke at flange; attributed to insufficient provision for expansion,
1,123	Scottish Hero	1898	Cast-iron valve chest burst, through original defects.

THE FLEETS OF THE MAIL LINES.

(From our own Correspondent).

The Moravia.

IN common with most of those who write on shipping matters, I fell into an error with regard to this vessel, both as to her name and as to her ownership. This I hasten to correct. For on her last voyage she was no longer a Hamburg American Liner, no longer even the *Moravia*. At the commencement of the year her original owners disposed of her to the well-known firm of Messrs. R. Sloman & Co., of Hamburg, and they had just renamed her the *Palma*.

Unfortunately the fears which I expressed as to her safety were only too well founded. She struck, in the tempestuous weather then prevailing, on the North Eastern bar of the fatal Sable Island on the 12th February, and almost immediately went to pieces. The first reports of the disaster were brought *via* Gloucester, Massachusetts, by a fishing vessel, and they seemed to indicate that her crew had lost their lives with the wreck. Happily it turned out that this was not the case. Though the vessel lay 12 miles off the shore the Sable Island lifeboat managed to take off the crew, though they endured very great hardships from cold and exposure, sufficient in the case of the second officer, who had been injured by a sea, at the time of stranding, to cause even fatal results. The ill-fated vessel was about sixteen years old, and was built on the Clyde by Messrs. A. & J. Inglis.

Missing Steamers.

Every recent instalment of these notes has had references to the terrible disasters which have characterised the winter season of 1898-9. The present notes contain the most serious of all. Few of my readers will escape having lost friends in the vessels included in the melancholy table which I here set forth. It includes eleven vessels, all of which are hopelessly overdue.

It will be observed that all of them are modern and well-equipped steamships, and it is to be remarked that of none has any trace up to the time of writing been found.

A few remarks about some individual ships may not be out of place. One would be led to believe that the *Almida*, first in the list, was overwhelmed by an earlier hurricane than the rest, but that a later gale was accountable for the loss of ten steamers, besides the serious damages to other vessels which have already been reported. The *Almida* was formerly the *Cedardene*, and it will be noticed that she is the only vessel in the list which was bound west at the time of her loss.

The *Laughton* was formerly known as the *Noord Braband*, whilst the *Arona* had recently had her name changed from *Lambert's Point*. The *Alleghany* and the *Minister Maybach* were tank steamers. The former of them, though her career was short, had had some strange adventures. She was the vessel which was sunk in the Delaware some five years ago by collision with the Belgian steamship *Caucase*, whereby her cargo of over a million gallons of oil was set alight as it came to the surface. The crew thereby had a somewhat narrow escape. The wreck was guarded by a watch boat. But owing to some alleged default on the part of the watchers the Allan steamship *Siberian* ran over her and vastly increased the damage she had sustained. After immense and long-continued efforts the wreck was righted, raised, and taken to Messrs. Cramp's yard. There it was sold. The purchaser took it to New Jersey and had the ship rebuilt and placed on the American register. I think this was her first trip in her new guise.

The largest of the vessels in the list is the fine steamer *Port Melbourne*, of the Anglo-Australian line. She was under charter to the National Steamship Company at the time of her loss.

On the 7th March no less than nine of these vessels were at the same time quoted as uninsurable. Such a sweeping away of steamships and their crews is unprecedented, and it is much to be prayed that the melancholy record may not only never be broken but never even approached in the future. It is somewhat instructive perhaps to notice that all the vessels in the list were Western Ocean ships and that none of them were going out in ballast.

The Bulgaria,

I am pleased to say, was reported safe at the Azores the very day after my last notes went to press. Somehow or other her engineers managed, when the weather improved a little, to mend the apparently irreparable steering gear, and after a friendly tow by the West India & Pacific Company's new steamship *Antillean*, she was able to do her 10 knots into port. Great praise and much honour—especially from the Kaiser—has been, no doubt very properly, showered upon Captain Schmidt, who had all the responsibility of this trying time. But surely the engineering staff, who kept the pumps going, and who devised and executed the repairs, have some substantial claims to honour and to reward.

The Pavonia.

In view of the fact that there will probably be an inquiry into the circumstances attending the serious damage to the steamship *Pavonia*, it is premature to make comments upon the causes of her accident. But it is interesting to note that her experience is not altogether an unprecedented one. There

was, three years ago, a somewhat similar mishap in the Pacific Ocean to a steamship, the *Bonnington*, which became, as far as could be seen, hopelessly overdue, and yet turned up, though her condition was such that she had to be treated as a constructive total loss. An actual total loss, however, she was not, for after a sale she was repaired, and is now, I believe, under another name, doing good work for a Japanese firm. To Captain Atkin, the master; to Mr. Duncan, the chief engineer, and to their respective staffs the greatest praise is due. It is much to be hoped that as warm recognition of their resourceful pluck will be forthcoming in England, as was so promptly meted out by the German Emperor to the heroes of the *Bulgaria*. But I venture to think that all their efforts would have been unavailing had the ship not been fitted with a donkey-boiler on an upper deck. Thanks to its existence the holds were cleared. Hand pumping alone might have been unable to manage the heavy task. Time after time we have seen the advantage of these installations, and I trust this phase of the accident will not be lost sight of, now that she is safely docked at Liverpool.

Messrs. Harland & Wolff

will be busy enough with repairs. On the 17th of March there reached their yard the s.s. *Germanic*, to be thoroughly cleaned up and overhauled after her unpleasant experience at New York. That there is little the matter with hull or machinery is sufficiently evidenced by the rapidity of her passage to Queenstown in spite of the prevailing heavy weather.

The day after she arrived at her builders' yard, the

P. & O. China

came in there. She has made a much more deliberate passage home, a speed of seven knots having been the maximum considered safe for her even in the land-locked waters of the Mediterranean Sea. This is scarcely to be wondered at, since the repairs which were effected at Perim, though they necessarily occupied a long time in execution, were simply of a temporary character. Her under-water wounds were stopped by a make-shift wooden shield backed and strengthened by the working in of some 1,200 tons of concrete. It will therefore be some time ere we learn what her owners propose to do with her.

The re-hearing of the inquiry into the causes of her stranding was not a long affair, though a large array of counsel were engaged on it. It having been abundantly shown that the constitution of the Court at Aden (which in the first instance tried the case) was not in accordance with law; it having further censured the acting second officer—Mr. Crawford—without affording him any opportunity for defending himself, the case really resolved itself into an inquiry as to whether or not the censure should be repeated by the Divisional Court which conducted the re-hearing. It was, however, proved that the officer in question carried out the orders given him by the master, who was himself on the bridge the last fifty minutes before the vessel struck, whilst Mr. Crawford had been off duty twenty minutes before the catastrophe. Under these circumstances the Attorney-General, who appeared for the Board of Trade, declined to formulate any charge against the acting second officer, and the Court therefore intimated that it was unnecessary for his counsel to address them. The object of those who insisted on the necessity of a re-trial of the case has thus been attained, and the insistence was fully justified.

The Cunard Company

have made a sweep of old ships indeed. Since I last wrote the *Bothnia* and *Scythia*—who have on previous occasions been reported sold—have really been disposed of. One has gone to Spain and the other to Italy. Owing to the high value of copper at the moment, the old favourites realised a price approximating 50s. a ton. The pair of sisters which now disappear were constructed a quarter of a century ago for their owners' New York mail line. It is long since either of them went to New York, however, with the exception of one visit last year paid by the *Scythia*, when she took an extra turn for the *Aurania*, broken down. Their chief employment in the long intervals of leisure has been the Boston line. There they were of little value, as their coal consumption was high—owing to the fact that they had their original compound engines—and their cargo capacity was limited, their design, naturally old-fashioned by modern standards, having been more for the passenger than for the freight trade. Their departure relieves the Cunard Fleet of some 9,000 tons of useless shipping, and makes, as has been pointed out by the *Shipping Gazette*, a total now of no less than 11 old bottoms disposed of in the last two or three years. All of them have gone to the scrap heap.

A Curious Error

on the part of a usually excellently informed shipping paper may be noted. The paper in question is French. But its information is generally as accurate as that of any of its British contemporaries. It is true that in making the mistake it was, in fact, endorsing the erroneous statement of another journal. Some one, it appears, had been noticing the circumstance that two old vessels of the Transatlantique Company were still at work as sailing vessels, one under the British, the other under the German flag. The writer of the paragraph I refer to felt that in some way a reflection was thus cast upon French honour. So it proceeded to show that the French were not alone in having old vessels at work. Naturally enough, they cited the jubilee *British Queen* of the Cunard Line, whose disappearance had not then become known. But not content with crediting her with her actual 50 winters, they added another 10 to her age, and confused her with the 2,000-ton ocean liner *British Queen*, which was the sister ship to the ill-fated *President* of the early days of Transatlantic navigation. In the same way they took the fleet-list of the West India Royal Mail and seeing, correctly enough, the names *Trent* and *Dee* amongst the vessels there, promptly concluded that they were the original owners of those names. The first bearers of the name in the fleet were of course wooden paddle vessels, and if now afloat would be nearly 60 years old. But they have both passed away more than a generation ago, and the *Trent* and *Dee* that now appear are screw steamers built of iron in the seventies.

Disasters

after the storm fog. The opening of the year saw heavy weather and powerful steamers overwhelmed in mid ocean. Then came the loss of the Dominion Liner *Labrador* on the Mackenzie Rock, fortunately without loss of life. An inquiry will, of course, be held, and we need not now say anything as to how she got where she did. But the manner in which passengers and crew were put ashore reflects great credit on Dominion Line discipline. The vessel is, of course, broken up, and the bulk of her mails are gone. She was a fine steamer, the finest up to the date of her launch that was built for the Canadian trade. She was constructed at Queen's Island, and very soon after her coming out in 1892, secured the record between Liverpool and the S. Lawrence for the mail service. She was the last of the single-screw ships which her line have built.

The loss of the *Castilian* came as rather a shock to those who had but a few days before been reading the account of the fine new 8,000-ton vessel which the Allan Line had put on to begin its improved mail service—a vessel which it was said had every appliance which modern experience and ingenuity could suggest for safety and safe navigation. Special attention was called to the wooden after-mast which Messrs. Allan's had fitted to her as to their previous vessels, so that one compass at least, mounted thereupon, might be perfectly reliable and free from all influence of metal. Here too there was fortunately no loss of life though the destruction of property was very considerable.

From the reports now to hand as to the prevalence of ice in northern latitudes, I cannot help fearing that we are not past the disasters of 1899. There is likely to be an unprecedented amount of ice when the iceberg season comes, and it may be expected that unusual caution in navigating the Atlantic will need to be exercised.

The South Eastern & London, Chatham & Dover Railways

have been very fortunate in obtaining the Queen as a passenger for one of their vessels across the channel. They seem confident enough of Parliamentary sanction to their union. For they have added to the joint fleet two new vessels during the last few weeks. One of these was the paddler *Mabel Grace*, built for the passenger service by Messrs Laird's, who seem to have obtained their custom since the Thames yards, to whom they were so long faithful, gave up the business, the last new paddler of the South Eastern, the *Princess of Wales*, having also come from Birkenhead. The other is a screw of smaller size for the cargo service. She came from Messrs. Denny, who had not previously had an order from this quarter.

The Canadian Steamship Company.

Trouble seems to be piled on trouble with regard to the new service of this line. The *Gaspesia*—as I noted last month—was frozen up in the S. Lawrence for weeks, and is not yet able to resume her sailings to the westward; this owing to the unprecedented ice of the present winter. Her March sailing is being taken by the 2,600ton *Dorset*, a vessel of some eighteen years old, built at Sunderland. Of the two steamships *Werra* and *Fulda*, which it was about to acquire from the Nord Deutscher Lloyd, the *Fulda* has been lost to it through the unaccountable accident which befell her in the graving dock at Birkenhead what time she was dry docked for the usual bottom sighting, which is one of the conditions precedent to purchase of steamers. The vessel was so damaged as to be condemned as a constructive total loss. In consequence of this she was sold by auction. The advertisement of the sale contained one curious item. Her dimensions, age, builders, engines, &c., were set out as usual. But the information that she had "condensers" was also afforded, as though in this she was especially well found. In the early days of steamers with compound engines it was not unusual to say that a vessel had "surface condensers," because the surface condenser was of comparatively late general adoption at that time. It was desired to show that the then modern form of condenser was fitted in lieu of the older jet condenser. But the appliance of one form or another have been with us so long that it seemed as necessary to tell us that she had them as part of her equipment as to mention that she had a bow or a stern. The ship was knocked down for £11,500, and was bought, it is said, on account of German owners who intend to refit her for service.

The Financing of Steamship Companies

has occupied a good deal of attention lately. This is no doubt due not only to the activity which is now prevailing in shipping circles, but also to the demand for larger, and therefore for more expensive, vessels. The P. & O. Company is applying to the Privy Council for a supplementary charter to enable it to issue debentures to an amount not to exceed a million sterling, if it considers it expedient to do so.

The Nederland American Company

is so pleased with the big twin-screw steamers *Statendam* and *Rotterdam*, which it has had built at Belfast, that it has ordered three more, to be called *Noordam*, *Potsdam*, and *Rijndam*. The accession of these vessels will enable it to maintain a weekly service of first-class new twin-screw boats which will certainly make their competition felt by other Continental lines. The company seems now to be in a thoroughly sound and prosperous condition. It is about to raise additional capital to the extent of a quarter of a million sterling. This course is rendered necessary in order to provide for the cost of the new steamers it has ordered.

The well-known firm of Houlder Brothers, which has the management of ten large steamships registered in the names of as many single ship companies, is converting itself into a limited company which shall own the fleet. The name of the new concern will be the Houlder Line, Limited, and its capital will be half a million sterling, nearly equally divided into ordinary and preference shares, with power to raise £200,000 in debentures. The fleet comprises some 43,705 tons of modern shipping, of which less than five thousand tons is more than five years old. All the vessels are fitted with installations for carrying frozen meat—a trade in which, as well from the River Plate as from New Zealand, the line has for long held a prominent place.

The West Hartlepool Steam Navigation Company, Limited, has about the same amount of capital as the Houlder Line. It acquires some twenty one steamers, ranging from the *Askehall* and the *Birkehall* of 7,000 tons each, down to the *German Empire* of 780 tons. It amalgamates the business of the West Hartlepool Steam Navigation Company with that of Messrs. J. E. Guthe. Four of its largest steamers, though provided for, are not yet delivered, and it will have the advantage of being under the direction of Sir Christopher Furness.

Messrs C. W. Kellock & Co.,

the reputation of whose firm is seen by the weight attached to their certificates of valuations in the prospectuses of the Houlder and West Hartlepool companies, have the business of disposing of the famous Bazin roller boat. She will be offered for auction by them on April 6th, and a full description of her appears in their list. The deck or platform of the vessel is 126 ft. 6 in, long, by about 40 ft. beam. The toughened steel rollers or discs upon which she runs are each of 32 ft. diameter. There is a water-tube boiler which is capable of supplying steam to engines of 500 H.P. The main engines are of the compound type, and, in addition, the rollers have their separate engines. It is said that when this strange craft was towed across the Channel from her port of equipment to Hull, she behaved splendidly. Intending purchasers are reminded of her possibilities as a raree show and as an advertising medium. But failing that, it is suggested that she would be valuable to shipbreakers as she contains much copper—now at so high a price. Indeed, it is rather cruelly suggested that the platform would make a bridge, whilst the rollers could be used for gas buoys or *caissons*. One will be curious to see what her ultimate fate may be.

The Barquentine "Cavan,"

recently converted at Londonderry from a paddler of the City of Dublin Steam Packet Company, is also on the market. She seems to have been practically rebuilt since she left the cross-Channel service

Messrs. Elder, Dempster & Co.

have been managing grandly for the African Steamship Company. Its tonnage is now a very small fraction under 95,000 tons. It pays a good dividend, and seems to be doing very well for its employees, for whom, as a somewhat hostile question in the House of Commons has just announced to the public, it has inaugurated an arrangement whereby its seamen and firemen, sailing to the not too salubrious West Coast of Africa, can, at reduced rates, make provision with well-known insurance companies for their wives and families in case they succumb to the climate or perils of the sea. It is worth noticing here that for their African service itself, Messrs. Elder, Dempster, who have long believed in it for the Atlantic voyage, are now adopting the twin-screw principle.

They are rapidly preparing to revive the old Beaver Line with fine new steamers, which are now constructing for them on the east coast. These vessels will also be of the twin-screw type, and will bear the names, "*Lake* ——," as did the vessels of the old Canada Shipping Company, whose goodwill Mr. A. L. Jones has purchased from the liquidator of the old line.

The Cape Mails.

The award has not yet been made by the Postal authorities of the new Cape mail contract. There is a story in circulation that a syndicate with a capital of £3,000,000 sterling has sent in a tender offering to reduce the contract time for the mails to Capetown to 14 days. The present period allowed is 19 days, though, of course, the limit is seldom approached. If there be truth in the rumour, there are likely to be very stirring times in this direction, as the old well-established companies—rich and popular as they are—will not let their position be assailed without a very stern resistance.

The P. & O. Company

are deprived of an old servant by the condemnation and sale of their old steamship *Brindisi*, which sustained serious damage some months ago at Bakan, Shimonoseki, in Japan, by collision with the native steamer *Tayeyama Maru*. The *Brindisi* is, fortunately for her owners, one of the smaller and older vessels of the line. But for local trading her size was a very useful one.

M. Paul Fanet.

I very much regret to announce the death of the charming and agreeable agent in England of La Compagnie Générale Transatlantique. M. Paul Fanet, who was liked and respected by all who had ever been thrown in contact with him, died but the other day at Boulogne at an age which was much less than his appearance would have led one to imagine he had attained. His life was shortened by the effects of two serious wounds, one in the shoulder and the other in the knee, which he had sustained nearly 30 years ago when fighting his country's battles in the Franco-German war. The compagnie will have difficulty in finding a man so thoroughly suited for the position as was their late agent in this country.

Richard Melhuish, Sons & Co.—We have recently received a copy of the latest edition of the Engineers' section of the Catalogue issued by Messrs. Richard Melhuish, Sons & Co., and which has just been published. This catalogue has again been revised up to date, and contains a very large selection of the latest patterns of stocks and dies, cutters, general machine shop and special precision tools, lathes, drilling and milling machines, and a variety of other apparatus and supplies incidental to all grades of engineering and contractors' work. This book contains over 300 pages, and is profusely illustrated with an extremely useful set of blocks. It is got up in very good style with stiff covers, and should therefore prove a handsome addition to a library of similar books.

THE BALANCING OF ENGINES.

IT will no doubt, we think, be interesting generally to many of our readers to give some information as to the balancing of engines as carried out under the Yarrow-Schlick-Tweedy system of balancing, particularly as we have been asked by some of our correspondents for information on the subject.

Although much has been done for years past in the balancing of the rotating elements by revolving counterweights usually carried by the cranks, still the increase of piston speed brought into prominence the unbalanced reciprocating elements, which was evidenced by the excessive vibration set-up thereby.

In the case of engines in which two or more cylinders are disposed with their axes in or substantially in one plane, these elements engender forces that act injuriously upon the support or foundation of the engines, as well as on the engine itself, in that they not only tend to displace the engine on its support in the direction of the piston rods, but also in a direction at right-angles, or substantially so, the tendency of which is to alternately tilt the whole engine from the ends of the driving shaft.

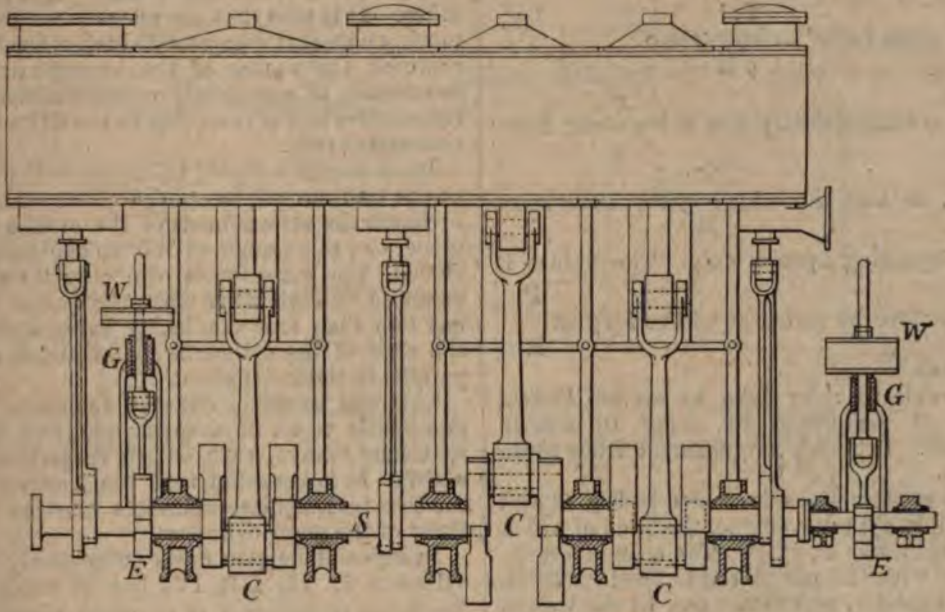

Fig. 1.

In 1892 Mr. Yarrow designed a balancing device consisting of reciprocating weights operated by the shaft, and adapted to counterbalance these injurious forces. He described and illustrated his system by a paper that was read and models which were exhibited in motion at a meeting of the Institution of Naval Architects in April, 1892. This system is substantially shown in Fig. 1 of the adjoining illustration, which represents a three-cylinder triple-expansion engine, the cranks C of which are set at angles of 120° to one another upon the shaft S. At the ends of the shaft eccentrics E are provided, each of which drives a reciprocating rod, carrying a weight W, the rod being guided in a suitable guide G.

The position of the eccentrics on the shaft, and the weight and travel and position of the weights in the direction of the axis of the shaft are so arranged that these reciprocating weights W counterbalance the usual unbalanced forces set up in the direction of the motion of the piston rods. The result of these arrangements was very conclusively shown by a model mounted freely on spring supports, and operated first without the reciprocating weights, and afterwards with them. In the first instance the engine, when operated, danced about merrily, and in the second instance, remained practically stationary. The valves and their gear are, of course, included in the calculations in estimating the weight, travel, and position of the balance weight.

Following on this method, Mr. Schlick in 1894 invented a method of balancing engines which have four or more cylinders arranged in one plane, so as to do without additional balance weights, by utilising the moving masses of rods and the like which already form part of the engine.

Mr. Schlick has estimated that in some marine engines of from 6,000 to 7,000 horse-power, two balance weights, each of from 20 to 30 tons are necessary, which involves a serious addition of weight to the machinery. The invention of Mr. Schlick consists essentially in the proper relative length of the crank arms, in the proper relation of the cylinder centres, and in the proper distribution of the weights of the moving masses so that the latter will act upon the crank shaft in such a manner that the resultant of the forces exerted by the moving masses in one direction upon the crank shaft, namely in the direction of the piston rods, and the resultant of the forces acting upon the shaft in the opposite direction, will be substantially equal and lie in the same straight line.

In the description of his invention Mr. Schlick has used the term "mass-force" to indicate the force engendered by the movement of a weight P in the direction of the piston rods, that tends to displace the engine in that direction, and he defines it in the following formula, viz.:—

$$\text{Mass force} = F \cos \varphi,$$

in which F indicates the centrifugal force of the reciprocating masses, if these forces were concentrated in the crank pin, and φ the angle formed by the crank and the direction of motion of the piston rod, as shown in Fig. 1*. The value $F \cos \varphi$ represents therefore the force that tends to displace the engine in the direction of motion of the piston rod when the crank is in the position making the angle φ with the piston rod. Further if v represents the constant velocity at which the crank pin revolves, R the radius of the crank, and g the acceleration of gravity, then,

$$F = \frac{P v^2}{g R} \text{ or}$$

$$\text{“mass force”} = \frac{P v^2}{g R} \cos \varphi.$$

At a uniform rotary velocity the value $\frac{\varphi^2}{g}$ is, however constant, as also the value $\frac{P}{R}$; the mass-force is therefore depending upon φ only. The values P and R can therefore be varied at will so long as $\frac{P}{R}$ remains constant.

It may be well to refer here to certain known arrangements of balancing in order to clearly differentiate Mr. Schlick's arrangement from those already known.

One of these constructions is shown in Fig. 2, and represents a triple cylinder engine, the rods of which are connected to cranks k^1, k^2, k^3. The central crank, k^2, is connected with the piston rod of the intermediate or central cylinder, and acted upon by the weight 2 L of the moving elements. This crank is in the same plane as the cranks k^1 and k^3, which are connected with the piston rods of the outer cylinders, and each is acted upon by a weight L. If it is assumed that the distance between the cylinders and the lengths of the crank's arms are equal, the forces referred to above are fully compensated or counterbalanced, and there will be neither unbalanced pressure due to momentum in the direction of motion of the piston rods, nor in a direction at right angles thereto, aside from the slight error due to the finite length of the connecting rods.

The same conditions exist in such an engine as shown in Fig. 3, which has two cylinders whose axes lie in exactly the same line, and whose moveable elements are of exactly the same weight. The piston rod of the upper cylinder is connected by a cross head and rods with two cranks, and the rod of the lower cylinder is connected with a crank intermediate of and opposite to the others.

In the two cases first described, we have two groups of moving elements which act with equal mass-forces upon two sets of cranks, and the relative arrangement of the cranks on the crank shaft is obviously 180° to one another. Turning now to the case of a twin cylinder engine connected with two cranks on a crank shaft, as shown in Fig. 4, it will be seen that the conditions are different, notwithstanding the fact that the mass-forces acting upon the said shaft are equal, and the cranks are set in the same plane, only the mass-forces exerted in the direction of motion of the moving elements counterbalance each other, while the couple of forces acting in the direction of the plane of the piston rods can in this construction nearly be balanced. This force may be reduced or diminished by a proper reduction of the distances between the cylinder centres, but the tilting movement of force cannot be eliminated.

A similar case exists where two such twin engines are connected to a single crank shaft or converted into a quadruplex cylinder engine, as in Fig. 5, so long as the two pairs of cranks are set at right angles to each other. It is true that the mass-forces exerted by the moving elements compensate each other in a measure, however the nature of the arrangement renders it impossible to completely counterbalance the forces, irrespective of the error due to the finite length of the connecting rods.

In an engine adapted to be started, whatever may be the position of the cranks on the crank shaft, and in which the arrangement of the cranks in the same plane, *i.e.*, at an angle of 180° to one another, is precluded, the mass-forces can only then be counterbalanced by each other when the power is applied to not less than four cranks, it being understood that the axes of the cylinders are arranged substantially parallel in the same plane.

This will be made clear by reference to the diagrammatic views of a quadruple and triple engine with four cranks, each shown respectively in Figs 6 and 7. It is essential that the moving elements of the two intermediate cylinders must be heavier than those of the outer cylinders.

In Fig. 6 the steam flows successively through the cylinders I, II, III, IV, but in order to shorten the steam passages, it is in many cases advisable to reverse the relative position of the cylinders III and IV. The triple-expansion engine shown in Fig. 7 has two low-pressure cylinders III. Dealing now with the quadruple expansion engine shown in Fig. 6, as an example, we will assume that the weights of the moving elements of the cylinders III and IV are represented by *p*III, and *p*IV, respectively, and that the angle between the two cranks is known, which for the sake of simplicity may be assumed to be 90°; and if further it is assumed that the distance between the axis of proximate cylinder is equal and all the crank arms are of the same length, the method of finding the weights of the moving elements of cylinders I, and II, and the relative angle of the cranks to which the pistons of those cylinders are connected, are as follows:—

In order to compensate the mass-forces exerted by the moving elements of cylinder IV by the mass-forces exerted by the same elements of cylinders I and II, it is necessary to provide for the last two cylinders cranks of equal length that lie diametrically opposite the crank of cylinder IV. The force exerted upon the crank shaft by the moving elements of cylinder II will, however, be greater than the force exerted upon the shaft by the moving elements of cylinder I, in proportion as the distance is between the centres of cylinders II and IV. is smaller than that between the cylinders IV and I; the sum of the forces acting upon the cranks of the cylinders I and II, should, however, be equal to the force exerted upon the crank of cylinder IV, accordingly a force equal to $\frac{1}{3}p$IV, and $\frac{2}{3}p$IV, respectively, should be exerted upon the crank shaft by the moving elements of the cylinders I and II, relatively to the force exerted by the like elements of cylinder IV. In a precisely similar

manner, the force exerted upon the crank shaft by the moving elements of cylinder III, that will counterbalance the forces exerted by the moving elements of cylinders I and II may be determined, viz. :—weights equal to $\frac{2}{3}p\text{III}$, and $\frac{1}{3}p\text{III}$, respectively, will have to act upon the cranks of cylinders I and II, in order to compensate the force exerted upon the crank shaft by the weight of the moving elements of cylinder III, as shown in Fig. 8, in which case the cranks I and II would have to be arranged diametrically opposite the crank of cylinders III.

If the relations that occur in the circle of the crank for the cylinder II., as shown in Fig. 9, are considered, it will be found that there should be exactly opposite the crank of cylinder III a crank upon which a force of $\frac{1}{3}p\text{III}$ is exerted; and at the same time there should be opposite the crank of cylinder IV a crank upon which a force equal to $\frac{2}{3}p\text{IV}$ is exerted.

In view of the fact that it is not possible to arrange two cranks at the same time in one plane, a single crank must be substituted therefore, the position of which, as well as the force acting thereon, will be determined by the resultant of the weights that would have acted on the two cranks. Hence if the value $\frac{1}{3}p\text{III}$ is carried according to a certain scale, to a prolongation of the crank-arm of cylinder III, and similarly the value $\frac{2}{3}p\text{IV}$ to a prolongation of the crank-arm of cylinder IV, the direction or position of the single crank for the cylinder II, and the weight that should act thereon, can be directly deduced from the parallelogram of forces. The position of, and the weight that should act upon, the crank for the cylinder I are obtained in the same manner.

If, therefore, it is assumed that the angle formed by the cranks of cylinders III and IV as shown in Figs. 9 and 10 is one of 90°, the following formulæ will result :—

$$p\text{I} = \sqrt{(\tfrac{2}{3}\,p\text{III})^2 + (\tfrac{1}{3}\,p\text{IV})^2}$$

$$p\text{II} = \sqrt{(\tfrac{2}{3}\,p\text{IV})^2 + (\tfrac{1}{3}\,p\text{III})^2}$$

$$\text{Tang}\ \alpha = \frac{\frac{1}{3}\,p\text{III}}{\frac{2}{3}\,p\text{IV}} = \frac{p\text{III}}{2\,p\text{IV}}$$

$$\text{Tang}\ \text{B} = \frac{p\text{IV}}{2\quad\text{II}}$$

α and B being the angles which the cranks II and I make respectively with the cranks IV and III produced.

Formulæ are given for the conditions of the cranks of cylinders III and IV, not being a right-angle, and of the weights acting on and angles of the outer cranks being known, but they are too lengthy to be given in this article. It will be understood that in making the final calculations the valves, pumps, and their gear are taken into consideration, and in the case of three-cylinder engines it is suggested that the balance can be effected by using a reciprocating weight in place of the fourth cylinder.

In 1895 Mr. Tweedy made some further addition to the mathematical treatment of the subject in the matter of engines which have four or more cylinders, the axes of which are not in the same plane, and in which other conditions obtain, forming improvements on the method invented by Mr. Schlick, which, however, our space will not allow us to give detailed particulars of; they can, however, be readily obtained from the patent specifications.

We think we have given sufficient particulars to enable our readers to gain some general idea of the system composed of the methods invented by these three gentlemen.

NAVAL MATTERS, PAST AND PROSPECTIVE.

(From our own correspondents at home and abroad.)

The Navy Estimates.

THE new navy estimates which the First Lord of the Admiralty presented to Parliament recently show a further increase in the money which he proposes should be spent upon the Navy during the ensuing financial year. This increase represents a sum of £2,816,000 on last year's votes, the total amount of the estimated expenditure being £26,594,000. There is an increase in the personal account of £452,600. The works vote is higher by £145,000, the ordnance vote by £161,600, the shipbuilding vote by £2,016,000, and various miscellaneous votes show an increase of £40,900. The total number of officers, seamen, and boys, coastguard and Royal Marines proposed for 1899-1900 is 110,640, being an increase of 4,250 on the number voted for the financial year just ended. The additions proposed are to meet the larger requirements of the Fleet, and are composed of 463 officers, 1,700 petty officers and seamen, 215 engine-room artificers and artisans, 1,000 stokers, 172 miscellaneous, 500 marines, and 200 boys under training. Steps are being taken to effect a simplification in the rules governing the sea and harbour time of all officers, which have long been felt to be in an unsatisfactory and anomalous condition. The system of granting leave on full pay to certain classes of officers on return from foreign service has been extended, so as to include all commissioned officers below the rank of flag officer, also the warrant officers. A new system has been inaugurated, under which the Admiralty may at their discretion grant sick leave on full pay for a maximum period of three months to officers who become unfit for service at home or abroad from causes beyond their own control. The examination for the entry of engineer students, and the regulations governing the course of training at Keyham College and in the dockyards, have been revised. Additions both in pay and numbers are to be made as regards the Royal Marine corps, and an increase in the number of officers and men in the Royal Naval Reserve is also provided for. As regards the new shipbuilding programme, it is proposed to commence in the dockyards two battleships (design not yet decided), two armoured first-class cruisers, 9,800 tons, three smaller cruisers (design not yet decided), and two sloops. By contract it is proposed to build two first-class torpedo boats to replace others struck off the list. The two sloops to be laid down are to be in their general character similar to the *Phœnix* and *Algerine*. They will be propelled by twin screws, and be of moderate draught suitable for river service.

The Criticism on the Estimates.

From some members of the House of Commons and a few of the daily papers criticism was to be expected, but in the House neither Mr. Labouchere nor Mr. Dillon succeeded in convincing more than a few persons of the necessity for their amendment to reduce the vote for *personnel*. Mr. Dillon in fact made himself ridiculous when he asserted that Mr. Goschen had in view the strengthening of the Fleet to a point superior to that of six great Powers. Sir Ughtred Kay-Shuttleworth also rose with the object of contesting the wisdom or expediency of the proposed extra expenditure, but before he had finished he was practically patting Mr. Goschen on the back. For, said he, it is far more economical to spend money by means of the estimates, which added real strength to the Navy, than under a feeling of alarm to make a sudden spurt, and spend a lot of money obtained by a vote of credit with little or no permanent results. Mr. Gibson Bowles apparently had some misgiving with regard to the new construction, for he seemed to think that we were not maintaining our lead as regards the time taken up in the building of warships. Delay has certainly occurred in the construction of battleships and cruisers since 1897, but this has been in part due to the dispute in the engineering trade, to the re-construction of plant by the manufacturers of armour, and to other circumstances connected with the delivery of guns and machinery. The great excess in the shipbuilding vote over that of last year, £800,000, was determined by four factors, said Mr. Goschen, previous liabilities, provision for the commencement of new ships, provision for repairs, and the necessary provision for coal, sea stores, &c. But however large the increase in the estimates for 1899-1900 may be, it may be taken for granted that the Admiralty would not have recommended it if the political situation in Europe had not called for the strengthening of the British Navy.

Portsmouth Dockyard.

There is to be no lack of work at this yard during the coming financial year, for the vote for new construction and repairs for the ensuing 12 months amounts to £1,195,611. The *Canopus* is to be completed, and the *Formidable* and *London* are to be advanced as rapidly as possible. The second-class cruiser *Gladiator* is to be completed, and the third-class cruiser *Pandora* advanced, while an armoured cruiser and a smaller vessel are to be laid down. Of the money allotted to this yard, £911,249 is to be spent on ships already in hand, £127,517 on the new vessels which are to be commenced, and £151,845 on refits. Some little disappointment has been experienced that so few concessions have been made to the various members of the dockyard. Of the ordinary work at this yard it may be mentioned that the *Gibraltar* is waiting to be taken in hand, and to undergo a thorough overhaul. The torpedo boat *Dasher* has received a new set of boilers, and the *Hasty* has gone to Hull for a similar purpose. The *Charger* and *Havoc* are also to be re-boilered before long. The oil fuel trials in the *Surly* continue, although it has been found practically impossible to do away with the dense volumes of black smoke which are caused by this fuel. Several alterations have been suggested and tried, but very little improvement is apparent. Work on the *Canopus* continues to be as brisk as ever, and the vessel was recently undocked and placed under the sheerlegs, in order to have her heavy weights lifted on board.

Old Names for New Warships.

The names which the Admiralty have selected for the battleships and cruisers of the shipbuilding programme put forward by Mr. Goschen in March and July of last year have met with the approval of nearly everybody, and the Admiralty Board is to be congratulated on its selection. The four battleships will be named after four of our greatest admirals. One, the *Russell*, is to be laid down at Hull; two others, the *Duncan* and *Cornwallis*, are to be laid down at the Thames Ironworks, Blackwall; and the fourth, the *Exmouth*, will be built at Birkenhead. One of the cruisers, to be laid down at Barrow-in-Furness, is to be named the *King Alfred*; two others, to be laid down on the Clyde, the *Africa* and *Leviathan*; and a fourth, to be built at Pembroke, will be named after the great Admiral Drake. Taking the names as they are mentioned here, the first *Russell* was so named in May, 1692, in honour of Admiral Russell, who fought the Battle of Barfleur, and was launched at Portsmouth in the following June. She has a fine record of service, one which would look well on a battle-honour flag. The *Duncan* is, of course, named after Admiral Adam Duncan, and will be the third of her name; the *Cornwallis* will be the fifth of her name, and she has also an excellent war record. The *Exmouth* will be the second of her name, and is named after the dashing Sir Edward Pellew. Of the cruisers, the *Alfred* will be the fourth of her name; the *Africa*, the third of her name; the *Leviathan*, the third of her name; and the *Drake*, the tenth of her name. The name Drake dates back as far as 1652, and all the vessels which have borne the other three names given to the new cruisers have done yeoman service to the country. A writer in one of the weekly service papers, although agreeing that the names are good, suggests those of *Montagu*, *Vanguard*, *Namur*, *Captain*, *Defence*, *Foudroyant*, *Plymouth*, *Monmouth*, *Torbay*, *Prince of Wales*, *Lennox*, *Buckingham*, *Tremendous*, and *Tonnant* as being more or less suitable for ships now building or likely to be built in the future.

Torpedo-boat Destroyers as Queen's Escort.

For the first time on record Her Majesty was escorted across the Channel by a flotilla of torpedo-boat destroyers on the occasion of her leaving for her visit to the South of France. The vessels which accompanied the *Calais-Douvres*, in which vessel Her Majesty made the passage, were the torpedo-boat destroyers *Chamois*, *Ranger*, *Crane*, *Teaser*, *Star*, *Violet*, *Flying Fish* and *Hunter*, commanded by Commander C. Treherne, R.N., and the Trinity Yacht *Irene*. Her Majesty was apparently pleased with her escort, for, just before the *Calais-Douvres* reached her destination, the Queen caused a general message to be made to the flotilla, as follows: "The Queen is very much pleased with the appearance of your flotilla, and wishes to make her appreciation known to the commander and the officers and crews." To this kind and appreciative message came the reply: "Please thank Her Majesty in the name of the officers and crews for her expression of appreciation." Shortly before the flotilla reached the Boulogne breakwater the signal was given for it to return, and a very pretty manœuvre was executed. The two columns of destroyers steamed round almost simultaneously, and in a few minutes had formed in line, and were on their way back to England. Her Majesty expressed her admiration of the handling of the flotilla of destroyers. Directly the boats had left the Queen full-speed trials were started, and in a little more than four hours the first of the destroyers, the *Violet*, had reached Portsmouth. A good deal of credit is due to the commanders and crews of the boats, especially to the officers and men of the engineering department, for the efficient manner in which the flotilla carried out the work of escorting the Queen.

Pembroke Dockyard.

Very little information about the new cruiser to be laid down here has been given out, as her design is as yet uncompleted. It is, however, known that her displacement will be 9,800 tons, and she will be named the *Drake*. The cruiser *Spartiate*, which was launched in October last, is to undergo the completing stages of her construction at Devonport, where she will be permanently attached. This cruiser should be completed for sea by August next. She is what may be termed an improved *Diadem*; all the other vessels of her class are being built in private yards. Her total cost will be about £550,000, but nearly £70,000 of this money will be spent upon her when she reaches Devonport. *Apropos* of the visit of the Duke and Duchess of York, for the purpose of launching the Royal yacht on May 9th next, His Royal Highness has consented to receive an address of welcome from the town council at Pembroke. Work on the Royal yacht continues to make good progress, but she will still be more or less in an incomplete state when she leaves this yard. The name at present given to this vessel is the *Balmoral*, a name which will probably be retained. Although the yacht is to be launched in May, she will not be sent to Portsmouth until October; and it is expected that she will make her first official appearance in the Isle of Wight during the Cowes season of 1901.

The Imperial Japanese Navy.

The work of increasing the navy of Japan goes on as briskly as ever, for during the past month the battleship *Asahi* has been launched at Clydebank, the destroyer *Shiranui* ("Will-o'-the-Wisp") at Chiswick, and the great cruiser *Kasagi* left Portsmouth a few weeks ago *en route* for Japan. As regards the battleship *Asahi*, she is the heaviest ever built by the Clydebank Shipbuilding and Engineering Co., and resembles very closely the *Shikishima*, which was launched on the Thames about five months ago. The principal dimensions of the *Asahi* are:—Extreme length, 425 ft. 6 in.; breadth, 75 ft. $2\frac{1}{2}$ in.; and depth, 43 ft. $7\frac{1}{2}$ in., with a displacement of 15,200 tons on a mean draught of water of 27 ft. 3 in. The armament will comprise four 12-in. breech-loading weapons mounted *en barbette*, fourteen 6-in. quick-firing guns, twenty 12-pounders, and eight 3-pounders; while the hull is pierced for four submerged torpedo tubes. The machinery, which will be supplied by the builders, is in an advanced stage, and consists of two sets of three-cylinder triple-expansion engines, each of which is expected to develop 7,500 H.P. The boilers, twenty-five in number, are of the Belleville type, with economisers, and the vessel will have a bunker capacity of 1,400 tons. The estimated speed is 18·5 knots, and when completed for sea the *Asahi* will be one of the most formidable battleships afloat. The *Kasagi*, which has just left for Japan, was built and engined at Cramp's Yard, Philadelphia, but received her armament at Elswick. One interesting feature about her is the disposition of her guns, which are mounted on the upper deck, forecastle, and poop, four torpedo-tubes only being carried on the maindeck. She has also, on platforms raised above the upper deck, four machine guns, the mechanism of which has been invented by a Japanese officer, but which were manufactured at Elswick. The remaining

Japanese vessel launched, the destroyer *Shiranui*, is one of six 30-knot boats, which the Japanese Government have entered into a contract with Messrs. Thornycroft to build and complete.

Two Notable Launches.

The launch of the first-class battleships *Implacable* and *Glory*, at Devonport and Birkenhead respectively, took place successfully last month. As regards the *Implacable*, she is the largest vessel ever built at Devonport dockyard, and in addition, she established a record for that yard in warship building, since she was laid down, on July 15th last, 5,300 tons of material having been built into her. A description of her has been given in these pages before, but it may be added that she is one of a trio of improved *Majestics*, the other two of which ships are the *Irresistible* and *Formidable*, now completing at Chatham and Portsmouth respectively. The launch was successful in every way, Lady Ernestine Edgecombe performing the launching ceremony. As the *Implacable* glided into the water her proportions in length and breadth, of 400 ft. and 75 ft. respectively, were seen to the best advantage. She has yet to have her masts, boilers, armour plates, &c., fitted into her, and for this purpose was berthed alongside the staff-captain's jetty. The first-class battleship *Glory* was floated out, and having been built in dock she was fitted with all her citadel and casemate armour, and most of the barbette armour, as well as having a considerable portion of the boilers on board, and all the auxiliary machinery in place and pipes and connections fitted. When she took the water she displaced about 9,000 tons. The christening ceremony was performed by Mrs. John Macgregor Laird, wife of the senior member of the builders' firm, and as soon as she entered the river, tugs took her to the Great Float to receive the remainder of her boilers, and be completed for sea. The *Glory* is the third of a series of four large first-class battleships which have been entrusted by the Government to Messrs. Laird to build since 1899.

Chatham Dockyard.

The new work for the coming financial year for this yard includes the completion of the *Goliath* and *Pioneer*. The *Irresistible* and the *Venerable* will be advanced. A new battleship and a new cruiser will also be laid down. The vessels which are to undergo a refit include the *Hood*, *Blenheim*, *Imperieuse*, *Grafton*, *Hawke*, *Immortalite*, *Scylla*, and *Archer*. Thus there will be ample employment for the large staff at this yard for the next twelve months. The bill, by the way, for wages for the last year is well over £5,000. The *Amphitrite* has been here, in order to have her hull surveyed by the officials. She met with a slight accident while entering the basin, running her bows against the caisson, and sustaining some slight damage. A large staff were immediately sent aboard her to prepare her for sea. The new armament for the *Dreadnought* has now been completed by the arrival from Woolwich of the 12·5 in. muzzle loaders. It will be remembered that she is being re-boilered, and her engine power has been increased. Altogether some £30,000 or £40,000 has been spent upon her, and it is a pity, therefore, that she is armed with obsolete muzzle-loading guns, whereas, if a few thousand extra had been spent, she might have carried modern breach-loading guns. The delay in the trials of the *Goliath* is said to be due to the engineering contractors being a little behindhand.

Rifle Practice in the Navy.

The annual return of rifle practice by the petty officers and seamen of the Navy for 1898, recently issued, shows us that although the general results were not so good as those obtained in 1897, the individual results were very good indeed, the highest score being two points above that of the previous year. 11,626 men took part in the firing, and out of this number 1,623 qualified as marksmen. Out of a total of 123 ships, from which complete returns have been received, four only were armed with the old Martini-Henry rifle, the remainder using the Lee-Metford. Petty Officer A. Gloyne of the *Royalist*, proved himself the best shot in the Fleet, as he scored 227 points out of a possible 240. The next best individual shot was F. Stratford, a Gunnery Instructor of the *Orlando*, who scored only two points less than Mr. Gloyne. But the general average was only 134·53, as against 147·78 for the previous year. The ship with the best record is the *Curacoa*, fifty-five of her crew taking part in the competitions, out of which forty-nine scored over 165 points, the average points obtained being 176·4 out of a possible 240. The results from the several squadrons showed that the Particular Service headed the list with an average of 155·99, and the South-east coast of America Squadron comes last on the list with 102·6 average points. As is mentioned above, all but four of the 123 ships which competed were supplied with the Lee-Metford rifle, and the low average is probably in some part due to the fact that the men have only recently been supplied with this weapon. Then again many of the stations at home and abroad have no proper range where practice can be carried out. When this omission is repaired, and the men get used to the steady firing of the Lee-Metford, the standard of rifle shooting should improve throughout the Fleet.

A New Process for Making Armour.

The delay which occurred last year in the manufacture of armour for the Navy will probably be repeated if it is true that Mr. T. A. Edison, a son of the great inventor, has discovered a process which is superior to any now in use. Experiments with a 6-in. plate, treated by this process, proved, it is said, that the plate was superior in resistance to 15-in. Harveyed plates and to plates 12 in. thick treated by the Krupp process. Presuming that special plant will have to be laid down for making armour-plates by Mr. Edison's process, it will be seen at once that the armour-plate manufacturing firms of this country will be obliged to go to an immense expense. This was what happened when the Harvey process took the place of that invented by Mr. Tressider, and also when the Krupp process was found to be superior to that invented by Mr. Harvey. Krupp-process armour, we are told, has only just passed the experimental stage in the United States, and is only being manufactured on a moderate scale by the Carnegie and Bethlehem companies in that country. The qualities of the Krupp armour which have proved it superior to that made by the Harvey process is its depth and hardness of base, extreme toughness of back, and immunity from cracks under numerous heavy impacts. The process of manufacture is not patented, but is a so-called trade secret, though not wholly so. As regards the cost of manufacture but little can be said except by those engaged in the business. The American companies claim that their output is smaller, and that the risks of losses are greater with Krupp than with the ordinary armour. According to all accounts, Krupp armour is in use in England, Russia, Germany, France, and Japan, and it is positively stated that as regards the principal British armour-making establishments they are not selling it to anybody for less than £117 per ton, which is considerably less than that which the American Government have offered the armour-plate manufacturers of that country. From this it will be seen that, if Mr. Edison's invention comes to anything, considerable trouble and expense is in store for the armour-plate manufacturers all over the world.

Sheerness Dockyard.

There is an abundance of work at this yard in all directions, and it is expected that the coming year will be one of great activity as regards the building and completing of vessels. Two new sloops are to be commenced, but they will not be laid down until a few months' time, probably not until after the *Vestal* and *Shearwater* have taken the water. Although the sloops *Condor* and *Rosario* were floated out nearly three months ago, they have not yet got the whole of their machinery on board. Work on the *Vestal* and *Shearwater* is being pushed forward as much as possible, and other work includes the completion of the cruiser *Prometheus*, and the *Basilisk*, sloop; *Speedy*, torpedo gun-boat; *Skipjack*, torpedo gun-boat; and *Goldfinch* and *Sparrow*, gunboats, will be refitted. The *Sanspareil* recently left here for Chatham to have her defects made good. It is expected that she will not be ready for sea until the middle of May. The *Pomone* is now being prepared for the fleet reserve. She will probably be placed on the roster for sea service in the place of the *Perseus*, which vessel was to replace the *Salamander* on the Mediterranean Station. The refit of the *Landrail* has been completed, and she is now ready to resume her duties. The *Onyx* has been placed in dock to undergo a refit, and the old *Wye* is also to be prepared for another trip. She is to leave here on the 8th of this month and goes to Sierra Leone and Ascension.

The French Navy.

The French Navy Estimates, which were presented to the Chamber last month, formed most interesting reading. It appears that the first demand was for 304,078,400fr., but the addition of some 5,000 men to the marine forces, and the expenses likely to be incurred by the navy taking a sufficient part in the coming exhibition increased this estimate by nearly 3,000,000fr. However, the Budget Committee reduced this somewhat, and proposed to the Chamber that a sum of 302,065,994fr. be allotted to the navy. M. De la Porte, in presenting the Estimates to the Chamber, said that France had made extraordinary exertions to increase her navy, and in proof of this, mentioned that in 1872 the Navy Estimates were only 118,000,000fr., but in 1890 they had risen to 201,552,516fr., and this year to more than 302,000,000fr. The outlay upon new construction has jumped from nearly 36,000,000fr. in 1890 to 92,689,000fr. in 1899. Turning to another subject, the French navy is to be condoled with on the disastrous explosion at Lagoubrun, near Toulon. Questioned in the Chamber concerning this affair, M. Lockroy said that the technical and judicial investigations were not yet complete. He was inclined to suggest that brown powder was probably the cause of the disaster, and attached no importance to the packet of dynamite which was found. The *Moniteur de la Flotte* says that there is reason to fear that fulminate of mercury had been stored in the magazines contrary to orders, and that this may have caused, even at a distance, the explosion of dry gun cotton, dynamite, and rapid-burning powders.

The "Brief" for the Engine-Room Artificers.

Seeing that the grievances of the engineer officers of the navy are likely to be ventilated in Parliament, the engine-room artificers have evidently considered the time opportune to offer a few suggestions, which, if carried out, would improve their own position. These suggestions they have issued in the shape of a " brief," as they term it, and their requests are certainly most modest. The regulations for promotion to the rank of warrant officer they would like to see improved, and especially the age qualification, which appears to press unduly upon the younger men. There seems no reason either why their request that the regulation obliging a candidate for promotion to be 35 years of age should be altered cannot be granted, nor that retirement should be at 50 years instead of 55, as is at present the case. Several other points in the " brief " could easily be conceded. If the grievances set forth in this document are all that the engine-room artificers have, it would be easy enough to remove them, but the question always arises as to whether the views of the whole of this class of men are represented.

The American and Swedish Navy Estimates.

The Navy Estimates of both these countries have recently been made public, and as regards the first-named, it is proposed to put 12, and probably 15, ships in hand. The 12 vessels which have been arranged for are three battleships of about 13,500 tons displacement, carrying the heaviest armour and most powerful armament of vessels of their type, to cost, exclusive of armour, 3,600,000 dols. each; three armoured cruisers of about 12,000 tons, to cost 4,000,000 dols. each; six cruisers of about 2,500 tons, of high speed, good cruising qualities, and most powerful ordnance suited to their type, to cost, exclusive of armour, 1,141,800 dols. each. The three vessels not yet decided upon are protected cruisers of 6,500 tons displacement, to cost 2,150,000 dols. each. As regards the navy of Sweden, this is to be increased by two cruisers of 3,300 tons, and Parliament has been asked to grant a supplementary vote of money to be used in modernising three cruisers which have become out of date. The reason that this supplementary vote has been asked for is said to be that Norway will shortly have four armed cruisers at its disposal, all more powerful than the Swedish vessels of the same class.

Devonport Dockyard.

The chief event of the past month at this yard was the launch of the *Implacable* on the 11th. She is the second modern battleship which has been built at this yard, and will be completed by October, 1900. According to Mr. Goschen's statement, in addition to the *Bulwark*, which is now preparing to build, and which it is proposed to complete by June, 1901, we are to have one of the new battleships he referred to, and a third-class cruiser, of which the design is yet to be decided, is also to be laid down during the year. The *Ocean* is to be completed by July 24th next, and the cruisers *Hermes*, *Highflyer*, *Hyacinth*, and *Spartiate* are also to be prepared for sea, as well as several torpedo boat destroyers built in other yards. The *Hecate* has been taken in hand for the purpose of being re-boilered. As regards the *Hermes*, this vessel was to have been delivered in October last, but the dispute in the engineering trade upset calculations a little, and it will now be impossible for her to commission until July next. The lengthening of No. 3 slip, from which the *Implacable* was launched, has been referred to before, but it is worthy of mention that this work has added very much to the dockyard's capacity for battleship construction. The new slip which is to be built on the sites of the two covered sheds at Mutton Cove, known as slips Nos. 1 and 2, is to be considerably longer than the present open slip. The successful issue of the trials of the *Psyche* has proved the worth of the work turned out at Keyham factory, and it is rumoured that more important work will shortly be given out to the factory. She is to be completed by the 28th of this month. The new funnel of the cruiser *Edgar*, which was made by the boiler makers at Keyham, and weighed nearly ten tons, has now been lifted into place. The *Edgar*, it will be remembered, was the cruiser which lost one of her funnels while crossing the Bay of Biscay during the recent bad weather. The *Skate*, torpedo-boat destroyer, which also met with an accident recently, by which she lost the whole of the blades of one propeller and two blades of the other, has now had her injuries attended to. The *Opossum* has also undergone some repairs, and has now resumed her instructional duties.

Experiments with Water-Tube Boilers.

During the debate on the Naval Estimates, Mr. William Allan, the Member for Gateshead, found another opportunity of attacking the Belleville water-tube boiler and especially its use in large vessels like the *Terrible*. *Apropos* of the bursting of a water-tube in that vessel he said that numbers of vessels like the *Terrible* are ruined by boiler explosions, and rendered fit only for scrap iron, and that the men down in the engine-rooms of vessels fitted with this type of boiler were in a state of tension, afraid at every moment lest the boilers should burst. The men in the *Terrible* he declared were panic-stricken. These statements are surely exaggerated; and if Mr. Allan enquired more closely into the matter, he would find out that the boilers were not always the cause of the trouble. The Admiralty, however, continue to pin their faith to water-tube boilers, and recently ordered a series of trials to be carried out on the gunboat *Sheldrake* with the Babcock & Wilcox type. These trials are not yet completed, but when they are the results will be compared with those obtained from the *Sharpshooter*, fitted with Belleville boilers, when she carried out precisely similar trials to those of the *Sheldrake* in 1895. The result of the first trial which the *Sheldrake* carried out was most satisfactory. She had to steam 1,000 miles under ordinary service conditions, indicating 1,500 H.P., using only three-fourths of her boiler power. On the trial in question an average of 1,500·3 H.P. was registered, giving a grate surface of 189 sq. ft., and a heating surface of 6,528 sq. ft. The coal consumption worked out at 12·31 per square foot of the grate surface, and 1·61 per I.H.P. 71 tons 14 cwt. of coal was burnt during the run, and efforts were to be made during the succeeding runs to further reduce the coal consumption. It is noteworthy that the engine-room staff had no previous experience with this boiler. The second trial was completed on the 17th ult., and this trial was eminently satisfactory, especially as regards economy in coal consumption; with the same heating surface and grate area, the power developed was 1,500 H.P., the quantity of coal worked out at 12·67 lbs. per square foot of grate surface per hour, and 1·6 lbs. per I.H.P. per hour. It was remarkable in both these trials that the efficiency of the boilers was better at the end of the run than at the commencement, and apparently they could have continued steaming so long as the coal lasted with the efficiency fully maintained. The third trial commenced on the 27th ult. The boilers fitted in this vessel are of British manufacture, and are made entirely of wrought steel; they are also largely used in the Mercantile Marine, and are giving most satisfactory results. If the remainder of the runs of the *Sheldrake* pass off without a hitch, and the coal consumption continues to be as small in comparison with a number of other types of water-tube boilers, it will augur well for the further adoption of Babcock & Wilcox boilers in the vessels belonging to H.M. Navy.

MARINE ENGINEERS' NOTES.

(From our own Correspondent.)

THE Institute of Marine Engineers, in their care of, and endeavours to provide a better class of, marine engineers, have scored a victory which will be all the better appreciated because of the long time taken to come to the end aimed for.

Formerly it was possible for a person to put in the three years' service at sea, and in some cases those who had never put in any time as engineers in a shop ashore were allowed to pass the Board of Trade examinations for second class certificates. It came about in this way. Some young man with a friend having an interest in the ship would get appointed as an assistant in the engine room and serve his three years there. These three years were accepted by the Board of Trade as satisfying the required service. And so it came about that men could be in charge of the engines who had never had an engineering training at all. Now this is changed. Every person who presents himself for examination for a second-class certificate of competency must have undergone a thorough training in the engineering shops ashore before he can try for it. The alterations which affect this are as follows:—

"Paragraph 22. Candidates for second class must serve as apprentice engineers for five years instead of three years; three years of the five must be spent in fitting or erecting; no service in drawing or boiler yard will count for more than 12 months; time spent in technical schools may be accepted under certain conditions; all applicants to produce testimonials of ability as an engineer workman. The sea service required cannot be performed in vessels with engines of less than 66 N.H.P. Sea service alone will no longer qualify a candidate for examination."

There is a further regulation bearing on this:—

"8. All applicants will be required to produce, in addition to the official discharge-certificates, testimonials as to their workshop service and as to their service at sea. The testimonials as to workshop service must be signed by the employer, and must testify to the applicant's conduct and ability, and state what kind of work he was engaged on (*e.g.*, fitting, erecting, &c.) and for how long."

Another regulation refers to service at sea:—

"9. Testimonials as to service at sea must testify to the applicant's sobriety, experience, ability, and general good conduct for at least the last twelve months' service at sea preceding the date of application to be examined. They must be signed by the master and chief engineer (or in case of testimonials to chief engineers, by the master and superintending engineer), and must clearly state whether the applicant was on regular watch and in regular charge of a watch, on the main engines or boilers. It is desirable that testimonials of candidates should be endorsed by the superintending engineer. No time spent in clerical work will be allowed to count."

All this is very excellent and it may show an example to the *deck* in the attempt to provide better efficiency. But there is one part of paragraph 22 which requires elucidation. That part is "all applicants to produce testimonials of ability as an engineer workman." In the present state of chaotic apprenticeship it is very easy to understand what that will mean, and as the Institute of Marine Engineers have kept pegging away at the better organisation and efficiency of the engineers of the mercantile marine, they must now take up the cause of the shops. The apprenticeship question requires reorganising under modern lines. It is impossible to change the modern machine methods of working in the shops, but it is not quite impossible to provide along with that a real training for apprentices, and there is evidence of a new spirit forming in the masters. They do not now so much look on their lads as items in cheap production, and set them to mind machines. There is a pride arising in some masters, and more especially in superintendent engineers, in their apprentices. Superintendents often boast of them when they turn out well or do a good piece of work. The signs of improvement are in keeping with the improved regulations of the Board of Trade; it is an improvement all round.

The Institute then can take up this regulation of the work of apprentices and see that the certificates conform to some rule. Already several engineering masters and superintendents have offered to come into line with regulations which might be drawn up by the Institute of Marine Engineers. They are willing to have their apprentices placed on some regulated system of work and instruction and examination, and it will be for the Institute to take up this question and arrange for it as they have done for the engineers at sea.

The Institute has also now made a new beginning with its experimental and electrical department, Mr. G. Halliday being convener of the Committee, and organising the work. At present there is a project on foot to wire the Institute premises, and later to provide an engine and dynamo for experimental purposes. There are also numerous experimental apparatus to be made, and these are being arranged to be constructed by the members. It is one of the rules that a member shall do something for the Institute, and though that rule is not enforced, it is expected that most of the members will comply voluntarily with the conditions. Perhaps it will be best to appeal to the interest which each member naturally has in the institution to which he belongs. In this way it is expected that a good laboratory will soon be got together.

Then there is the museum of marine engineering fittings. This department can very soon be extended and improved by additions. It is most likely that the new additions or the most of them will be supplied by makers of new designs of machinery. It is on those lines the models have been supplied up to the present, but there are other things which may be sent. Models, for example, of entire fittings of, say, valve gears which the students may work with, and take measurements, and fittings like induced draught arrangements. It will take time to form, but constant and regular application will soon bring things together.

A paper on auxiliary machinery on board ship was discussed during the month. The results of tests were given which astonished many of the members, but on inquiry it was found that they were very nearly in accordance with what was found in general practice. For example, it was found that 250 lbs. of water were required per I.H.P. There are long base pipes which convey the heat away. Then the working of the engines is by *anybody*, and there is not the slightest attempt to economise steam. One man who is working the engine will put on steam when it is letting down a load, and put on the brake to keep it back. So that the engine and load will be working in one direction, and the brake against them both. One feature is the enormous drop in steam pressure, At the boiler it will be 78 lbs. according to one of the tests, and an indicator card will show 4·37 lbs. average pressure. Mr. Girvan, used to the hydraulic system, had much to say in favour of its economy and ease of manipulation. There was not much fear of pipes becoming frozen if proper care was taken of them, then they were perfectly noiseless, which was a great advantage.

The statement of accounts for the Institute of Marine Engineers has come to hand, and we have only space for the general items. The accounts are made up from 1st February, 1898, to 31st January, 1899.

FIRST-CLASS TORPEDO-BOAT, "COBRA," BUILT FOR THE AUSTRO-

AN GOVERNMENT BY MESSRS. YARROW & CO., LTD., LONDON.

A petition is being prepared to be presented to the House of Commons in favour of shipowners in England employing British seamen. Mr. W. Clark Russell, the novelist who writes of the stirring adventures of the sea, has taken the question up, and he appeals to the British people to sign the petition. He heads his appeal, "Food for Great Britain in War! Shall the foreign sailor extinguish the British merchant sailor?" He states that shipowners for years, taking advantage of an ignorance which is largely due to indifference, have been insidiously sapping the life of the British merchant seaman by stealthy but insistent importation of the foreigner, whose recommendation is that he is cheap, that he does not murmur when bad food is given to him, that he is tractable, and that shipmasters choose him in preference to their own fellow-countrymen. "Brassey's Naval Annual" for 1895 states that our "mercantile marine is manned by 235,000 men, of whom 55,000 only are British seamen," which is a little more than half the naval reserve of France. Mr. Russell concludes, "The process of diminution then is steady, and unless the decay is arrested promptly, and by Imperial measures, this country will find itself face to face with a condition that to my mind is little less than appalling—I mean the total and, I fear, the irremediable extinction of the British merchant seaman."

A circular supporting Mr. Clark Russell has been issued from the University, Durham. In this circular it is pointed out that the Government have asked for an expression of opinion in the matter of the excessive employment of foreign sailors in the mercantile marine and the employment of "alien seamen in our merchant vessels deprives many of our own countrymen of employment, and also that it is incurring a very serious risk to leave the food supply of the nation so largely in the hands of aliens in the event of a naval war."

The Marine Engineer has to add its word to the movement, and it is that though in all the industries of the country a new spirit is forming against the old Manchester doctrine of money being the only bond between masters and men, in this, the noblest of English industries, it appears to be living longest and will die last. It may be true that English seamen give trouble, but they are not wholly to blame. Those troubles are mainly due to the Manchester doctrine—after the discharge no further responsibility. And it has gone on until the men on their side have claimed the same rights, namely, disregard for the interests of the employer. If the British sailor is to be again what he was in the days of Drake, of Hawkins and of Oxenham, the shipmasters must learn that the man's cause is their cause and his rights their rights. What interest would Drake's sailors have had in him had he paid them their wages and sent them going with no further claims on him? It was because they knew they had a claim on him and that he would never repudiate the claim which made them stick to him and made them willing to follow him against the Armada, round the world or anywhere. Until this spirit is again created in our merchant seamen, by the masters of our ships, our merchant fleet will remain a disgrace to the Empire.

ELECTRICAL NOTES.

(From our own Correspondent.)

IT has always been found difficult to obtain a reliable governor for marine steam engines, and whether that recently invented by Mr. E. W. Naylor is so still remains a question. There are two steam inlet valves and two exhaust valves. There is also a sickle-shaped contact disk, part of which is insulated, while the other part is a contact plate. There is a permanent contact brush connected to a small generator or some source of current; also two brushes in contact with the sickle-shaped disk, which complete the connection with the steam inlet valves. The other pole of the magnets is connected through wires which join. The governor is coupled up to a draw rod, which by its movement in or out varies the period of contact of the brushes, and so controlling the cut off of the steam from 1 to 100 per cent. of the stroke. The other brushes are adjusted by hand until the best compression is obtained. When the crank is turned, at a certain place the steam valve and exhaust valve are full open. Further round the brush allows release of the steam valve, continuing the rotation the exhaust valve closes. On the return stroke the opposite valves come into operation.

Lieut.-Com. Dana Greene on Electricity on Board Ship.—After all the reports from officers who saw the use and advantage of electrical appliances on board ship in the United States navy, it is understood that the naval officers of the Naval Bureau have decided against its further use. Lieut. Greene, however, is of a different opinion, and in a paper before the A.I.E.E. he gives expression to those views. He says the first-class battleship requires about 2,000 I.H.P. to drive all the auxiliaries at full load, and a first-class cruiser 1,200 I.H.P. About one-half in each case may be supposed to be in action at one time. We can have compressed air, hydraulics, steam, or electricity as the motive power for these, and the Lieutenant sums up in favour of steam or electricity. The disadvantages to steam are danger to life by bursting of pipes, injurious heating of living quarters; but it is simple and reliable, it can be worked by anyone, but is very wasteful. During the late war all the regular war vessels of the United States were fitted with electric lighting plants, and the larger ships with electric auxiliaries, such as ammunition hoists and ventilating fans. Two of the *Brooklyn's* turrets were controlled by steam motors and two by electric motors. All the electrical apparatus stood the test well, and pleased the officers, and they were contrasted with the steam motors. From a careful trial of the steam auxiliaries of U.S. *Minneapolis*, a first-class protected cruiser of about 7,500 tons displacement, with three screws, and a trial speed of 22 knots per hour, it was found there was a great consumption of steam by the auxiliaries. There were between thirty and forty steam auxiliaries, and more than 150 separate steam cylinders. Indicator cards were taken on all the auxiliaries, and losses from leakage, condensation, and radiation carefully estimated, and the water evaporated carefully measured. The steam used by the main engines per hour was 33,620 lbs., and by the auxiliaries 10,146·7 lbs., so that the auxiliaries consumed nearly 25 per cent. of the total coal used. The main engines consumed an average of 20·63 lbs. of steam per I.H.P., and the auxiliaries 119 lbs. per I.H.P. per hour, the lowest being 55·06 lbs. and the highest 318·68 lbs. per I.H.P. per hour. It is reported that the H.M.S. *Powerful* used 8,300 tons of coal from England to Hong Kong, of which 3,400 tons were required for the auxiliaries, which works out to over 40 per cent. On a ship the auxiliaries consume at least 20 per cent. of the steam, which is twice as much as is consumed by them on a central station. The Lieutenant assumes for a first-class battle-ship 1,000 H.P. effective at the motors he would have a three-wire system of 221 to 250 volts. He assumes an efficiency of 82 per cent. for engine and generator, and an average line and motor efficiency of 80 per cent. The total efficiency would be 65·6 per cent. To develop 1,000 H.P. at the motors would require 1,500 H.P. at the engines. It would then require about 30 lbs. of steam per effective H.P., and allowing for losses 37·5 lbs. per I.H.P. per hour as against 119 lbs. by steam on the *Minneapolis* test. The weight of electric plant as against steam plant for auxiliaries will for a first-class battleship be 275 tons as against 100 tons for steam, but there would be a saving of coal of from 200 tons to 400 tons.

Wireless telegraphy may become of enormous advantage to the Mercantile Marine and the Navy, and the latest experiments may be of some interest. These were made by Herr K. Strecher, at Miggelsee, some twelve miles from Berlin. He used, says *Electrician*, an induction coil of 50 c.m. spark and a motor-driven mercury interrupter, breaking the primary circuit 20 times per second. The wires connected to the transmitting and receiving apparatus were 100 metres long and parallel to one another, the distance between them being 5·7 k.m. Bronze wire, supported on ordinary telegraph poles and insulators, was employed. There were no obstacles between the wires. Several wires were connected in parallel, but the experiments did not show whether or not this was an advantage. The transmitting station was on a hill 800 metres from the eastern end of the lake and the receiving station at the western end. In spite of wet weather and difficulties in keeping apparatus dry the experiments, which were continued for some weeks, were successful. Strecher's conclusion is that using horizontal wires signals can be transmitted over a distance 50 times the length of the wire.

As auxiliary machinery is so much spoken of it is interesting to learn that Messrs. W. H. Allen, Son, & Co., of the Queen's Engineering Works, Bedford, have constructed two surface condensing plants for the Glasgow Corporation Electricity Works, the pumps, air and circulating being driven electrically. They are three-throw, have no foot valves, nor have the brackets packing rings. Each condenser has a tube surface of 1,250 square feet, and consists, says *Engineering*, of a circular cast iron shell with the supporting feet and all the necessary branches cast on. It has bronze tube plates, and solid-drawn bronze tubes ¾ in. in external diameter. The holes in the tube plates are drilled and tapped to form recesses for tape pinchings, which are screwed up tight by means of bronze ferrules, making the joints round the tubes steam and water tight. The steam circulates round the outside of the tubes, and the cooling water passes through the lower half of the tubes in one direction, then in the opposite direction through the upper half of the tubes. Two large doors, one at each end of the condenser, give easy access to the tubes for cleaning and re-packing. The pumps are driven through Hollick's friction gear. The large friction wheel of this gear is keyed to the crank shaft, while the smaller wheel is carried by a vibrating frame centred in the crank shaft, in such a way that by elevating or depressing a handle the two wheels can be put out and into gear with the small pulley in the dynamos spindle. This pulley lies between the two wheels, and the apparatus is put into gear by pulling down the swinging frame, thus pinching the motor pulley between the two wheels, while the thrust is balanced by the belt tension. A feature in this system is that the motor can be started by itself, and when running at the correct speed the pumps can be put into operation by means of the friction lines. The pumps run at a speed of 150 revolutions per minute, and the motor at 800 revolutions; 15,000 lb. of steam are dealt with per hour. The centrifugal circulating pumps have 7 in. suction and discharge branches; the revolving discs are 12 in. in diameter. Each pump can discharge 1,000 gallons of water per minute through the condenser against a total head of 10 ft. The speed of the pump is 530 revolutions per minute. The motors for air-circulating pumps are wound for 500 to 600 volts.

THE AUSTRIAN TORPEDO-BOATS.

We give a double-page plate-illustration of the Austrian torpedo-boat *Cobra*, constructed and engined by Messrs. Yarrow & Co., Limited. The Austrian Government had two made of the same type, one by Messrs. Yarrow and the other by a continental firm. Messrs. Yarrow built the *Viper*, which, on trial, reached a speed of 26½ knots on a three-hours' run with a load of 26 tons on board. In consequence Messrs. Yarrow received the order for the four remaining boats of the order. The *Cobra* is 152 ft. 6 in. long and 15 ft. 3 in. beam, constructed of galvanised mild steel, and sub-divided by transverse bulkheads. She is stronger in the scantling than usual. The armament consists of three pivoted torpedo-tubes for 18 in. diameter torpedoes, two placed forward and one aft, and two quick-firing three-pounder guns. The engines are triple-expansion, with three cylinders 18 in., 26 in., and 39½ in. in diameter by 18 in. stroke, driving a single screw. Steam is supplied by two water-tube Yarrow boilers. The boat is fitted with electric light engines, steam steering gear, forced draught engines, fresh water condensers, electric ventilating fans, and pumping engines. The engines can develop 2,000 I.H.P. The bunkers carry sufficient coal to give a radius of action of 1,500 nautical miles at 10 knots.

With steam pressure of 180 lbs. and 340 revolutions per min., and with a load of 44 tons, she made a speed of 24·265 knots. The speed is lower than that obtained by the *Viper*, but the load was much greater. It was considered desirable to make the armament of the *Boa* equal to that of a destroyer. If the *Viper* could carry 26 tons and make 26½ knots a destroyer of three times the displacement and three times the *power* should be loaded to 78 tons, and her speed of 30 knots would fall to 27½ knots, which is only one knot higher than the *Viper*. But a torpedo-boat like the *Boa* would cost only about one-third as much as the destroyer, and would require from 10 to 12 men less to work her—about 30 for the torpedo-boat, and 50 for the destroyer.

The third of the four torpedo-boats passed through her official trial on Wednesday, March 15th, and obtained a speed of 24·3 knots for three hours' continuous steaming. The guaranteed speed was 24 knots, carrying a load of 44 tons. This load represents the boat in absolutely complete sea-going condition, with bunkers full and all armament on board. On March 21st the official trial took place of the torpedo-boat *Python*, the last of the four torpedo-boats. The Austrian authorities were represented by Commander Ladislaus von Sztranyavszky (Naval Attaché), Mr. Grond, and Mr. Groger. The speed realised was 24·34 knots, the revolutions being 350 and the steam pressure 170 lbs. The load carried was 44 tons, representing the vessel fully equipped under service conditions.

FLOATING OF H.M.S "GLORY."

On Saturday morning, March 11th, Her Majesty's first-class battleship *Glory* was floated from Messrs. Laird's shipbuilding yard at Birkenhead.

Owing to the recent death of Mr. William Laird the ceremony of floating was kept as quiet as possible, but a vast concourse of people had assembled to witness it.

The usual service was read by the Rev. J. W. Hughes-Games, M.A., Vicar of Birkenhead, and the vessel was christened by Mrs. John M. Laird, wife of the senior member of the builders' firm.

The *Glory* is of the *Canopus* class, designed by Sir William H. White, K.C.B., Director of Naval Construction, and as this class of vessel is now well-known, we will offer only a short description. Her dimensions are:—Length, 390 ft.; breadth, 74 ft.; mean draft, about 26 ft. 6 in.; displacement, 12,900 tons; freeboard forward, 22 ft. 6 in., aft, 19 ft.; I.H.P., 13,500; speed about 18¾ knots; having a total stowage for about 2,000 tons of coal. The armour is of Harveyed steel, and there is a protective deck, from lower edge of armour, covering machinery, magazines, and other vital parts.

The ship is lighted throughout with an installation of about 750 electric lights, and equipped with six search lights of 30,000 candle power, each of which is capable of being worked by dynamos under protection.

The officers and crew are accommodated on the main and belt decks.

The upper deck extends from stem to stern without a break, and above it is a continuous bridge deck extending the whole length between the barbettes, and on this deck are the conning towers, surmounted by navigating bridges (which will be about 36 ft. above water), and the chart house.

The masts, two in number, are built of steel, fitted with military and signalling tops, and are already in place, and complete with their derricks for hoisting boats, &c.

The armament of the *Glory* will consist of four 12 in. 46-ton guns, mounted in barbettes, in pairs, and firing a projectile weighing 850 lbs., with a powder charge of 148 lbs. There are 43 quick-firing guns in all—12 6 in. on the main and upper decks, mounted in casemates protected by 6 in. armour, 12 12-pounder, six 3-pounder quick-firing, eight small machine guns, and five field guns. There are also four submerged torpedo tubes for 18 in. torpedoes.

The main propelling machinery constructed at the Birkenhead Iron Works consists of two sets of engines of the triple-expansion inverted type of the latest design. Each set is placed in a separate engine-room. The cylinders are H.P. 30 in., I.P. 49 in., and L.P. 80 in. in diameter respectively, with a stroke of 51 in.

The boilers, 20 in number, are of the Belleville type (with economisers), working at a pressure of 300 lbs., and are placed in three separate water-tight compartments.

The *Glory* illustrates the advantage of building these large battleships in dock in preference to building them on a slip and launching them, as she floats out with all her citadel and casemate armour and most of the barbette armour in place; indeed, all the armour-plating would have been completed had it not been for the press of work in Sheffield rendering it impossible for armour-plate manufacturers to make delivery as early as required. A considerable portion of the boilers is on board. The whole of the auxiliary machinery is in place, and their pipes and connections are being fitted. The main engines are erected on board with the exception of the cylinders, so that the vessel, as floated out from the building dock, is in a far more advanced state than would have been the case had she been launched in the ordinary way, her displacement on floating out being approximately 9,000 tons.

This feature is brought into singular prominence at the present time as Her Majesty's ship *Implacable* of 14,900 tons displacement, for which the machinery of 15,000 H.P. is also being built by Messrs. Laird Brothers, was launched from Devonport on Saturday March 11th, her weight being about 4,500 tons.

It is expected that the *Glory* will be ready to hoist her pennant within six months, but the *Implacable* is not expected to be ready for hers for about fifteen months.

H.M.S. *Glory* and H.M.S. *Implacable*, launched at Devonport, are coated with Hartmann's Rahtjen's improved composition (the Red Hand brand), which is also applied to 283 of Her Majesty's vessels.

The *Glory* will have a complement of 750 men.

It may be mentioned that the name *Glory* was originally taken from *Gloire*, a French man-of-war captured by the *Chester*, one of the British Channel Fleet in 1709.

A *Glory* also participated in Lord Howe's victory on the 1st of June, 1794, and in Sir Robert Calder's victory off Ferrol in 1805.

After the ceremony the guests adjourned to the model-room, where refreshments were served. Over the subsequent proceedings Mr. John Macgregor Laird presided, and proposed the toast of "The Queen," which was duly pledged.

Mr. J. M. Laird next proposed "Success to the *Glory*." He said they had that day witnessed the interesting ceremony of floating one of the largest battleships ever built in any country. It was usually the custom of the firm to have a large number of representative people with them in watching that ceremony and wishing God-speed to the ship, but on the present occasion they had decided to make the function a more quiet one. The reason for this was known to all of them. It was due to the very recent loss the firm of Laird Bros. had sustained through the death of Mr. William Laird, the senior partner. Under these circumstances he felt it would not be seemly to have a very large gathering, and they therefore had as guests that day only a few there who were directly interested in the family or the works. Another point which made it rather sad for some of them—in fact for all of them—was that it was little more than twelve months since Mr. John Laird, who had for so many years been a most active partner in the firm, was also taken from them. The worth of both Mr. William and Mr. John was testified to by the unanimous sympathy and respect which was shown, and he was sure that the sympathy and respect shown, not only in Birkenhead, but far beyond it, had been a great encouragement to those left to carry on the concern. Such a concern as that of Laird Bros., building ships of the type of the *Glory*, and the large variety of other works they had to deal with, could not be carried on, however willing the partners might be, without the assistance of a faithful and efficient staff. They had been fortunate in having left to them by the late partners such a staff. Perhaps it was unequalled in experience in warship building in the world. It was the intention of the younger men who had now control of the concern to follow, if they could, in the steps of their predecessors, and carry on the work on the same lines, and trust would be imposed as hitherto in all the members of the staff. They relied on the experience of the older members, the energy of the younger and the *esprit de corps* of the whole of it. There was one point in connection with this he would like to mention on that, the first time he had made any public remarks recently—and that was that their trusted engineer, Mr. Bevis, who had been with them and associated with his (the speaker's) father and uncle, and with his grandfather before them for a period of 45 years, had decided at the end of 1898 that he would retire from the active control he had taken and become more of a consulting engineer. They had, however, the full benefit of his cordial assistance and advice in all points of difficulty, and they were fortunate in having his son, Mr. Ratsey Bevis to step into his position as engineering manager, and under his régime with all his energy and vigour he felt sure that in that department Laird Brothers would still continue to lead. Having noticed these few points he came to the business of the day, and that was to ask them all to drink success to the vessel they had just seen floated from the dock. He did not propose to make many remarks, but would say that she was the third of a series of four large first-class battleships which had been entrusted by the Government to their firm to build since 1889. That was a record to which no shipbuilding firm in the country could show an equal. Some firms had had three, some two, and some one, but none had had four except themselves. The first was the *Royal Oak*, and she, when she was built, was floated out from the same dock as the *Glory*, having only about 55 per cent. or a little over half her total load displacement worked into her, and taking twelve months to finish her. In the case of the ***Mars*** she had about 65 per cent. of the total final weight into her when floated, but in the *Glory* they had gone a step further, and she had fully 75 per cent. Instead of twelve months, as in the case of the *Royal Oak*, and nine months for the *Mars*, they quite expected to have the *Glory* away by her contract date, and within six months from the present time. No other battleship ever floated or launched was in so far advanced a condition. He was glad to say that the Government had recently ordered the *Exmouth*, one of the vessels of the *Duncan* class; she was to be larger, more heavily armoured, more heavily armed, and faster than any battleship ever designed by any country previously. She was to occupy the dock just vacated by the *Glory*, and if they could rely upon the workmen of Birkenhead to do their best, to be regular in their attendance, and when at their work to do a full day's work, he had no hesitation in saying that they would equal, if not beat, the results they had attained in the *Glory* in rapidity of construction, and it would be an encouragement to them as employers of labour to undertake more orders, which were always competitive, from the home Government, or from foreign Governments, and bring further work to that district which had in the past turned out so many famous ships, but of which their firm remained the sole representative of the largest class of shipbuilding work! The present week had brought plainly before them the question of navy expenditure, and he thought Mr. Goschen in his speech had fully explained the advantage and intention of the Government to keep apace with all shipbuilding that was done in any other country. It would be perhaps unnecessary in these days to say very much more about the importance of a strong navy, but during the last year it had been more brought before their notice as an object lesson than previously, and if a strong navy was to be the means of bringing peace and preventing war, then it was a very small insurance premium for them to pay to meet the wise, though perhaps somewhat lavish, expenditure that was being made by the present Government. They all knew that if war were to come the expenditure now proposed would be nothing if it were to secure the safety of their food supply and the protection of their world-wide commerce. But whether the *Glory* was destined to be a ship to prevent war, or, if it came to the worst, to take part in war, they must wish her success, and he begged them to join with him in doing so. Other toasts followed.

In addition to the *Glory*, Messrs. Laird Brothers have the following work in hand, the ***Express*** and ***Orwell*** now undergoing their steam trials, two single-screw sloops, H.M.S. ***Mutine*** and ***Rinaldo***, of 980 tons and 1,400 H.P., and a 30-knot destroyer for the Russian Government, which will shortly be ready for launching; a paddle-wheel steamer, launched last month, for the South Eastern Railway Co.'s Folkestone and Boulogne traffic, intended for a very high speed, and with nearly 6,000 H.P. engines; a first-class battleship for H.M. Navy of 15,000 tons and 18,000 I.H.P., to be named the *Exmouth*, is to be laid down immediately in the building dock just vacated by H.M.S. *Glory*.

In addition to the foregoing vessels, there are in progress a set of twin-screw engines of 15,000 H.P. for H.M.S. *Implacable*, which is building at Devonport Dockyard, and a set of water tube boilers for H.M.S. *Blanche* to replace her original locomotive boilers.

THE INSTITUTION OF CIVIL ENGINEERS.

WATER-TUBE BOILERS FOR MARINE ENGINES.

AT the ordinary meeting of the Institution of Civil Engineers on Tuesday, the 7th March, Mr. W. H. Preece, C.B., F.R.S., the President, in the chair, two papers relating to recent advances in Marine Engineering were read.

The first paper, on "Water-Tube Boilers for Marine Engines," by Mr. J. T. Milton, consisted mainly of a description of the various types of water-tube boilers most in use for marine purposes in this country. For all recent vessels of the Royal Navy water-tube boilers of different type had been adopted, while very few had been fitted in merchant steamers.

The difference in practice in the two cases was accounted for by the different conditions of the services required. In most vessels of the merchant service economy of coal consumption, durability of boiler, and facility of cleaning and inspection, were of far more importance than considerations of weight and space in proportion to power exerted; while in some war-vessels the importance of obtaining very large powers on small weights outweighed the questions of coal economy and durability.

The question of economy in boilers was largely dependent upon the completeness or otherwise of the combustion of fuel in the furnaces. The conditions required for perfect combustion had long been well known, but they were difficult of realisation in actual working practice. So far as the merchant service was concerned the general introduction of a new type of boiler would depend upon its economy obtainable under ordinary conditions of work, not upon the results of special trials. In some boilers the conditions for perfect combustion could be approximately met by very careful stoking, but were unattainable under ordinary working conditions at sea with ordinary firemen. In such boilers, while excellent results might be obtained upon special trials, conducted under the direction of skilled engineers and with expert firemen, inferior performances were obtained at sea in every-day service.

Reference was made to the question of circulation of water in water-tube boilers, and experiments made upon this subject by Mr. A. F. Yarrow, Mr. J. I. Thornycroft, and by the late Mr. A. Blechynden, were quoted. The experiments of the last-named were made upon a full-sized boiler. The boilers first described and illustrated were those made with comparatively large tubes. They comprised the types known as the Belleville, which was so extensively used in the large vessels of the Royal Navy; the Lagrafel d'Allest, used in the French Navy and Merchant Marine; the Niclausse, and the Babcock-Wilcox, the latter being the type most frequently adopted in the few cases in which water-tube boilers had been used in British merchant vessels. Amongst small-tube or "express" boilers used in light vessels, such as destroyers and small cruisers, the Normand, Yarrow, Thornycroft, Reed, and Blechynden boilers were described. Descriptions were also given of the Fleming and Ferguson, Mumford and Haythorn boilers.

With water-tube boilers, owing to the small quantity of water contained in them and the high rate of evaporation obtainable, automatic feeding was essential. Some types of apparatus providing for this were described.

For prolonged work, as compared with short trials, the author considered that straight tubes were very desirable, as much greater confidence could be felt in a boiler where all the tubes could be seen through, than in one where much had to be taken on trust, and good results could not be expected to be obtained from mechanism in which implicit confidence was not reposed.

MACHINERY OF WARSHIPS.

The second paper, on "Machinery of Warships," by Sir A. J. Durston, K.C.B., and Mr. H. J. Oram, R.N., M.Inst.C.E., gave particulars and remarks on the construction of warship machinery and details of the results obtained since the date of the paper read at the Institution in November, 1894.

In 1893, an Admiralty committee recommended that the total boiler heating-surface per I.H.P. at natural draught trials should be not less than 2·5 square feet, and that the increase of power due to forced draught should be reduced. The effect of this was seen in increased weight of water-tank boilers over those given in the last paper.

All the vessels described had triple-expansion engines.

In an appendix particulars were given, first, of recent battleships. In the *Majestic* class the boilers were larger and engines more substantial than in ships built under the "Naval Defence Act," the power was easily obtained and the forcing was moderate. The boiler-tubes were fitted with cap ferrules, and no trouble had been experienced with leaky tubes. Particulars of the *Canopus* class, which would soon be ready for trial, showed a considerable decrease in the weight of machinery per I.H.P. The steam pressure and ratio of cylinders had been increased from that in older vessels, and Belleville boilers with economisers were fitted. The machinery of the six vessels of the *Formidable* class was similar to that of the *Canopus*, but more powerful.

Particulars followed of first-class cruisers, of which the *Powerful* and *Terrible* were fitted with Belleville boilers without economisers, and showed a decrease in the machinery weights on cruisers built under the Naval Defence Act. The steam pressure and ratio of cylinders were greater than in these last-named vessels. In the *Diadem* and *Argonaut* classes, the steam pressure and ratio of cylinders were still further increased. Belleville boilers with economisers were fitted.

Of the second-class cruisers, the *Talbot* class with water-tank boilers, the boilers were all single-ended, and more heating surface per I.H.P. was allowed. In the *Arrogant* class Belleville boilers were fitted. There was a decrease in the weight of machinery compared with the preceding 9 vessels and vessels built under the Naval Defence Act.

Another table gave particulars of the new third-class cruisers. These vessels were fitted with water-tube boilers of the small-tube type. The machinery was 150 tons lighter than in preceding vessels of similar type and same I.H.P.

Particulars followed of the Torpedo-Boat Destroyers. They were fitted with triple expansion engines, running at 350 to 400 revolutions per minute, and with water-tube boilers of the small-tube type. The speed varied from 26 and 27 knots in the earlier boats, to 30 knots and over in the newer ones. The machinery was made as light as possible, and the boilers were subject to considerable forcing. Reference was made to the *Viper* with Parson's marine steam-turbine.

All recent large engines and some of smaller size had two L.P. cylinders. With four cylinders the twisting moment was more uniform, and the cranks could be more easily arranged to minimize vibration. The weight and length of engines were thereby increased. Piston valves were generally fitted to the H.P. and I.P., and flat valves to the L.P. cylinders. The sequence of cylinders and angles of cranks were such as to reduce vibration as much as possible. In recent four-cylinder engines the power developed in each of the two L.P. cylinders had been made about half that in each of the other cylinders and the working parts made smaller. In the *Terrible*, experiments had been carried out with propellers connected and disconnected to test the effect on vibration of varying the angles of the cranks. The results and also the calculated inertia forces and couples were shown. With the present arrangements vibration in this ship had disappeared. In most fast-running engines it had been also found advisable to fit suitably arranged balance weights to the crank arms.

With reference to induced draught, further experiments with this system had not shown any advantage except that the stokeholds were open. There was also liability to overheating of the fans.

Further experience with water-tube boilers had led to their general adoption for warships. In considering the type most suitable, the principal points to be considered were weight and space required, economy and durability. On account of the last two considerations, boilers of the large-tube type had been adopted for the larger vessels. The Belleville boiler was fitted in these vessels, and in recent cases these had been fitted with economisers, the number of tubes in the generators being reduced. Trials on shore showed twelve to fifteen per cent. increase of economy due to the use of these economisers.

The *Salamander*, with Babcock-Wilcox boilers, had successfully passed through her trial.

The *Seagull*, with Niclausse boilers, was at present undergoing trials.

In the smaller fast vessels, to reduce weight, boilers of the small-tube type were generally fitted. Experience had shown that the ordinary life of the tubes of the Belleville boiler, under ordinary circumstances, would be not less than two commissions. In small tube boilers this life would generally be much less.

Zinc slabs, though still of use in arresting corrosion, could not from the nature of construction of water-tube boilers be so effective as in water-tank boilers. The parts of the boiler near the feed-water inlet appeared to be very subject to corrosion, and this appeared to be due to the liberation of air and other gases from the feed-water at this part. It was endeavoured to minimize this action by using distilled water whenever possible. In Belleville boilers the economizer tubes in which the feed-water was first discharged were galvanized inside as well as outside.

Some cases of bursting of tubes had occurred, due in most cases to their choking with dirt.

In recent vessels the steam pressure had been considerably increased. No difficulties of importance had been experienced due to this. The effect on the weight and space required was shown in an appendix.

In the discussion which followed the papers Sir E. J. Reed showed himself in favour of the water-tube boiler for other reasons. Sir Edward thought that all the heating surface of the water-tube boilers was better brought into use while only the part of the tube nearest the tube plate was of much use for co-operation in the case of the return tube boiler. He had a recollection of experiments he made in conjunction with Mr. C. Wye Williams with tubes surrounded with water and the hot gases going through them. The water space through which the tubes passed was divided into compartments, and the evaporation produced by the tube in each was measured. When this was done it was found that almost all the evaporation had taken place in the compartment next the tube plate. But Sir Edward had forgotten one thing when he made the statement; he forgot that the tubes with which he had made the experiments were new and without scale, while the tubes in use in future tube boilers are by no means without scale. Further than that it happens that where the evaporation is greatest there also the deposit of scale is greatest, and the thicker the scale the greater is the resistance to transmission of heat. It comes therefore about that the scale and the tubes soon strike a balance with the result of a better distribution of evaporation along the tube. More evaporation takes place at parts of the tube nearer the smoke-box end, while less takes place at the parts of the tube nearer the tube plate next the combustion chamber. It is thus the chimney gases are lighter in temperature at the end of a long voyage with a corresponding loss in efficiency.

Professor Kennedy raised a still more important question when he hinted that a division of the work of the engine from the work done by the boiler in trials would give better information of what was going on. It is quite useless to anyone who is anxious to know what the boiler is really doing to tell him how much coal is required per I.H.P. The engine may be doing all sorts of things, and in any two cases it may be doing unlike things so that no comparison can be made. What one wants to know is the evaporation of the boiler per pound of coal under different conditions of firing. In the shop trials of the boilers, or in their mooring trials, they are sometimes given, but hardly ever in other cases. The trials ought to be conducted so that the performance of the engine is obtained and also the performance of the boiler, and these quite separately.

Mr. Manuel, of the P. and O., also raised an important question with special reference to the merchant service. That was the consumption of coal per I.H.P. as shown by the figures given in Sir John Durston's paper and the performances of the merchant service. In hardly any case where full power was developed was there less than two pounds of coal consumed per I.H.P. While in the merchant service he had a case which he recollected of about the same horse-power, 6,000, where with Howden's forced draught they had 1·5 lbs. of coal consumed per I.H.P. And then thrown in with this is the safety to the stoker and want of constant anxiety to the engineer. Mr. Sampson thought Mr. Manuel had not made sufficient allowance for the different engines and the waste of auxiliaries. The conditions of working the engines and the arrangements of steam pipes in the navy and merchant service are altogether different. Also, there is the human factor, and the water-tube boiler was more humane than the other. Mr. Sampson should have heard the remarks made by engineers and stokers who have worked water-tube boilers. They are not flattering, and they do not appear very grateful for the humane treatment to which they have been subjected. Of the question of combustion Mr. Milton felt himself more free to speak, and even to go into the chemistry of the question. But, after all, the chemistry of the question does not carry us far; it is the arrangements in the construction of a boiler for completely consuming the furnace gases, which are interesting. Of these arrangements Mr. Milton awards the highest position to the Scotch boiler, and the fact is true, that the Scotch boiler is arranged to give good combustion; but there is another fact equally true, that there are other boilers of the most unlikely design for producing complete combustion which do so nevertheless. And this permits an enquiry whether there are not other conditions besides the construction of the boiler which lend themselves equally to the production of complete combustion.

After Mr. Robertson, Mr. List, of the Donald Currie Line, pointed out that they had reached the limit in the tank-boiler in size and pressure, and if higher pressures were required, they would require to look to the water-tube boilers to supply what they wanted. There is no question that Mr. Milton was right when he said the conditions to be fulfilled in the Merchant Service were quite different to those in the Navy. But it was not true to say the water-tube boiler adopted by the Admiralty was without economy. From what he heard the engineers and stokers were very well pleased with the working of the Belleville boiler. He did not say it was the best boiler. The Engineer-in-Chief of the Navy, being a practical man, had the problem of the supply of steam set before him, and had to choose the best he could obtain. And the Admiralty were quite right in their policy, and deserved the thanks of the nation for fitting war vessels with water-tube boilers.

Mr. Davey addressed himself to the question of circulation, and spoke of the important experiments by Mr. Yarrow, which showed that it did not matter which leg of a bent tube was heated, the circulation of the water would continue to go in the same direction when once it had been started. He gave the case of a mine shaft full of air. The air got heated at the bottom and no circulation would take place. As soon, however, as the air was set in motion by an impulse on the top of one shaft it continued to go in that direction, and kept up the circulation down one shaft and up the other.

Mr. Wingfield spoke of the reference to a bent tube naturally being made thinner owing to its being bent. It was quite true that a tube did become thinner when it was bent backwards and forwards until it weakened and broke, but in the case of the bent tube of a boiler this was true to a very small extent. He also pointed out that Mr. Milton was not quite right in saying that the difference of heat of the water in the tube placed for measuring the circulation did not do so. The difference of heat was due to various causes, and only a part of that heat could be said to be due to that which caused circulation.

Sir Wm. White was satisfied from the discussion that the Engineer-in-Chief had been going on the right lines in fitting water-tube boilers in war ships.

Sir John Durston spoke of the long-time trials at full power and three quarters power with all the boilers in operation at other times with a proportion only of them in work. He pointed out that when large vessels went through their trials steaming at full power for 57 hours without a hitch, and in another case 59 hours without any trouble, they were on the fair way to success. And it must be remembered that this type of boiler was new and they were making improvements.

THE INSTITUTION OF MARINE ENGINEERS.

THE FIRST DECADE—PAST PRESIDENTS.

(*Continued from page* 356.)

SIR ALBERT JOHN DURSTON, K.C.B., R.N., born 25th Oct., 1846, at Devonport, educated at Mr. Robert Barnes' school at Newport, Isle of Wight, from which, in Feb., 1866, he entered by Civil Service examination, H.M. Dockyard, Portsmouth, as an engineer student. He served there under the late Mr. Andrew Murray, who was chief engineer until June, 1868. In that year he entered the Royal Navy as assistant engineer with seniority in June, 1866. During a portion of this period, from November, 1865, till he entered the Navy, he was a student at the school of Naval Architecture and Marine Engineering, and as such attended there during the winter six months, or from November to April of each of three years.

In October 1869, he was appointed to H.M.S. *Ocean* in China, and returned home in that ship in June, 1872.

Captain (afterwards Admiral) Sir William Hewett, K.C.B., R.N., commanded him during this commission, and Vice-admiral Sir John A. Fisher, K.C.B., R.N., now Commander-in-Chief of the North American and West Indies station, and recently controller of the Navy, was commander.

In the usual course Sir John received his promotion to

engineer R.N. in 1871. In October 1872 he was appointed for duty as an assistant engineer in H.M. dockyard at Portsmouth, and in 1877 he was promoted to first assistant to the chief engineer, and in the same year he received special promotion to chief engineer R.N.

Sir John continued to serve under the much esteemed late Edward Newman as his first assistant till 1881, when he was promoted to chief engineer of H.M. dockyard, Sheerness, and at the death of his dear friend and former chief in 1883, naturally succeeded him as chief engineer of Portsmouth yard.

In 1888, Sir John was transferred to the Admiralty as chief engineer inspector, and was promoted to engineer-in-chief of Navy in April, 1889, in succession to the late Richard Sennett, who at that time left the Admiralty to join the firm of Maudslay, Sons, & Field. In 1888, Sir John was promoted to the rank of inspector of machinery R.N., and to chief-inspector of machinery R.N. in 1893, and he is now the senior engineer officer in the Navy.

During Sir John's period of office, the machinery of the Navy has been more than doubled in I.H.P., and the steam pressure has been also practically doubled from 155 lbs. to 300 lbs. per square inch. The water-tube boiler has replaced the locomotive and cylindrical type.

Sir John has not been without appreciation from his Sovereign. Her Majesty created him a C.B. in 1895, and a K.C.B. in 1897. He is a vice-president of the Institution of Naval Architects, and past president of the Institute of Marine Engineers, and honorary member of the Institute of Engineers and Shipbuilders in Scotland. His clubs are the United Service, Royal Naval Engineers and North Surrey Golf.

Sir John has read many scientific papers before the Institution of Naval Architects, and takes part in all their discussions. His experiments on the effect of grease on the transmission of heat through the plates of boilers, and on their temperature on the fire side have been of great service to those who have to construct boilers.

WILLIAM HENRY WHITE, C.B., LL.D., F.R.S., was born at Devonport, February 2, 1845, and educated at the Royal School of Naval Architecture, South Kensington, while it was under the charge of the council, the Admiralty supporting it. In 1867 he came out at the head of the list of students of the school, and became a Fellow of the Royal School of Naval Architecture. When he left he was appointed to the construction department of the Admiralty, and in 1883 he had risen to be Chief Constructor. From 1870 to 1881 he held the position of Professor of Naval Architecture, both at the Royal School and the Royal Naval College, and still attended to his duties at the Admiralty. From 1883 to October, 1885, he was away from the Admiralty organising and directing the shipbuilding department of the Elswick Works of Sir William Armstrong & Co., and while there built a number of warships for foreign Governments of great speed. The Lords of the Admiralty sent for him to come to them again, and then appointed him Director of Naval Construction and Assistant Controller of the Navy. The work of the Admiralty in providing for the increasing needs of the Navy is growing year by year, and Sir William has been kept of late years at high pressure. Under the Imperial Defence Act of 1888 he had to design and build a new squadron for the protection of trade in Australasian waters, the cost of which was £850,000. In 1889 he had to provide another set of 70 vessels at an estimated cost of £21,500,000, which were to be completed in five years. From 1886 93, 131 vessels had been completed and added to the Royal Navy under Sir W. H. White. He is an LL.D. of Glasgow University, Fellow of the Royal Societies of London and Edinburgh, Vice-President of the Institution of Naval Architects, Past President of the Institute of Marine Engineers, Member of the Council of Mechanical Engineers and of the Institution of Civil Engineers, Honorary Member of the Institution of Engineers and Shipbuilders in Scotland, the North-East Coast Institution of Engineers and Shipbuilders, and the Society of Engineers; Member of the Iron and Steel Institute, the Association Technique Maritime of France, the Royal United Service Institution and the Royal Institution, Fellow of the Royal School of Naval Architecture, the Imperial Institute, and the Society of Arts. His "Manual of Naval Architecture" is the standard work, and it has been translated into German and Italian. He has contributed numerous papers on the science and practice of shipbuilding to the societies of which he is a member.

PETER DENNY, LL.D., was born at Dumbarton, Oct. 21st, 1821. His father, William Denny, was a shipbuilder, and he died in 1833, leaving a widow with 11 children. Peter remained at school until his 14th year, and after was engaged as a clerk to the local sheriff's officer, and then at Christie's Glass Works. Here he remained until 1843, when he became a pupil of his brother William, manager of Napier's shipyard at Govan. Later he joined his brother Alexander as a naval architect in Paisley.

The premises occupied by the father was called the Woodyard, which was on the west side of the Leven, a little below the bridge. The father had first been a carpenter, then managed as partner, then as proprietor. His brothers were William, mentioned above, James, Alexander, and Archibald. William was the most able. When Peter left to be with him he wrote: "My brother William kindly asked me to come and stay with him in Glasgow, and he would make a shipbuilder of me, setting me at once to work on plans at his lodgings. I felt it so difficult and strange that I would have given it up at any moment; but with his usual kindness he had patience with me and persuaded me to stick to it. I did, and soon got confidence, and progressed so that he was able to take me in as an assistant in the Govan Yard, I think towards the end of the year, August, 1843, at 30s. a week.

At the close of 1843 Peter joined his brother Alexander at Paisley, where he prepared specifications, plans, &c. William returned from America in 1844, when he, Alexander and Peter formed a partnership under the name of Denny Brothers, as naval architects. In 1845 they started as shipbuilders, on the east side of the Leven shore. Up to 1845 wooden vessels from 50 to 200 tons were built at Dumbarton, but Denny Brothers started building with iron at once with the paddle steamer *Lochlomond*, of 95 tons and 70 N.H.P., and during the same year they built the paddle-steamer *Rob Roy*, of 30 tons and 15 H.P., and the screw steamer *Water Witch*, of 240 tons and 35 H.P. The *Water Witch* was the first mercantile screw steamer built on the Clyde. Out of some 530 vessels which the firm has built only four have been sailing vessels. In 1846 Alexander left them and started with Archibald for themselves; and James came home from America and joined William and Peter, under the new name of William Denny & Brothers.

In 1850 Peter Denny proposed to his brothers that he should commence an engineering business in the town, so he entered partnership with Mr. Tulloch, of Greenock, and his brother-in-law, Mr. John MacAusland, the partnership being designated Tulloch & Denny, but in 1852 this was changed to the present name—Denny & Co.

In 1852 William Denny & Brothers built for the Cunard Co. the iron screw steamers *Australian* and *Sydney*, each of 1,400 tons and 300 N.H.P. They were at once sold for the Australian Mail Service. In the same year the *Alps* and *Andes*, each of 1,440 tons and 300 H.P., were built, and they were the first screw steamers of the Atlantic passenger trade. The engines, made by Tulloch & Denny, were of the "beam-geared type," with 66 in. cylinder and 54 in. stroke. The steam pressure was 6 lbs., and consumption of coal 5 lbs. per I.H.P. In the year 1854 Peter Denny wrote: "A great calamity to me took place in the death of my brother, William, aged 39. I was so depressed and disheartened that it needed all the encouragement of my friends in consenting to carry on the business, being so imperfectly qualified as to the technical and practical work, and having the necessity of the commercial department wholly upon myself." The firm also lost James Denny in May, 1862, and the whole control of the firm was left for some years in the hands of Peter. Some time in 1867 he asked Mr. Randolph, of Randolph & Elder, for help with regard to the advantages of compounding the engines, when he was told to find out for himself and pay for it, as Mr. Randolph had done. In 1868 they built and engined the *Batavia* for the Cunard Co., which turned out a complete success.

Iron and Steel Institute.—The annual meeting of this Institute will be held, by kind permission, at the Institution of Civil Engineers, Great George Street, Westminster, on Thursday and Friday, the 4th and 5th of May, 1899, when the President-elect (Sir William Roberts-Austen, K.C.B.) will deliver his inaugural address; and papers promised by Professor J. O. Arnold, Sheffield, Mr. H. Bauerman, London, Mr. E. Disdier, Bilbao, Messrs. Jeremiah and A. P. Head, London, Baron H. Von Jüptner, Donawitz, Austria, Professor H. Louis, Newcastle-upon-Tyne, Mr. Bertrand S. Summers, Chicago, and Professor Wiborgh, Stockholm, are expected to be read and discussed. The annual dinner of the Institute will be held in the Grand Hall of the Hotel Cecil on May 4th. The autumn meeting of the Institute will be held in Manchester on August 15th, 16th, 17th and 18th.

NAVAL ENGINEER APPOINTMENTS.

The following appointments have been made at the Admiralty from February 24th to March 24th, 1899:—

Allden, F. A., engineer to the *Tauranga*, to date March 4th.
Anstey, H. C., engineer to the *Pembroke*, for the *Amphitrite*, to date March 13th.
Apps, W. R., chief engineer to the *Pembroke*, for the *Fortc*, to date March 13th.
Ash, H. G., assistant engineer to the *Vivid*, supernumerary, to date March 18th.
Ayers, R. B., engineer to the *Victory*, for the *Starfish*, to date March 3rd.
Basson, H., engineer to the *Repulse*, to date February 24th.
Beal, W. E., fleet engineer to the *Wildfire*, for Sheerness Reserve, to date February 23rd.
Bingham, P., engineer to the *Victory*, for the *Teazer*, to date March 1st.
Bolton, A. W., engineer to the *Victory*, for the *Violet*, to date March 3rd.
Boyle, J. C. M. (probationary), assistant engineer to the *Warspite*, to date March 28th.
Brown, J., to be engineer, R.N.R.
Chamberlain, E. W., engineer to the *Warspite*, to date March 28th.
Church, P. D., assistant engineer to the *Pembroke*, for the Reserve, undated.
Collingwood, R., acting chief engineer to the *Vivid*, to date February 24th.
Collingwood, R., acting chief engineer to the *Vivid*, additional, to assist chief inspector of machinery in supervision of machinery and boilers in torpedo-boats and destroyers, to date March 9th.
Coomber, T. G., fleet engineer to the *Pembroke*, for the *Dreadnought*, to date February 23rd.
Coomber, T. G., fleet engineer to the *Pembroke*, for the *Northumberland*, to date March 9th.
Crisp, A. S., engineer to the *Centurion*, for the *Whiting*, to date January 7th.
Davis, W. K., engineer to the *Tamar*, for the *Hart*, to date February 21st.
Denbow, W., engineer to the *Pembroke*, for the *Warspite*, to date February 24th
Denbow, W., engineer to the *Warspite*, to date March 28th.
Denny, J. T. H., fleet engineer, has been placed on the retired list of his rank.
Downer, J. M., staff engineer to the *Pembroke*, for the *Dreadnought*, to date March 9th.
Duffell, W. J., engineer to the *Vivid*, for the *Sunfish*, to date February 24th.
England, A. C., to be assistant engineer, R.N.R.
Evans, A. (probationary), assistant engineer to the *Warspite*, to date March 28th.
Graham, W. J., chief engineer to the *Vivid*, for the *Phœbe*, to date March 26th.
Grant, H. W., assistant engineer to the *Royal Oak*, to date February 23rd.
Green, D. P., engineer to the *Royal Sovereign*, for the *Banshee*, to date March 31st.
Guyer, T. S., engineer to the *Victory*, for works of Messrs. Thompson, Glasgow, to take weights, &c. of *Kestrel*, to date March 13th.
Haigh, F. E. P., assistant engineer (temporary) to the *Warspite*, to date March 28th.
Hall, F. M., assistant engineer to the *Vivid*, supernumerary, to date January 21st.
Ham, J. W., engineer to the *Barfleur*, for the *Fame*, to date January 7th.
Hewitt, J. B., engineer to the *Sans Pareil*, to date February 24th.
Hobbs, P., engineer to the *Tamar*, for the *Handy*, undated.
Hockey, S., staff engineer to the *Pembroke*, to assist chief inspector of machinery in supervision of machinery and boilers in torpedo-boats and destroyers, to date March 9th.
Hosken, W. E., engineer to the *Victory*, for the *Vulture*, to date February 24th.
Jackson, E., fleet engineer to the *Galatea*, to date March 1st.
Johnson, C. H. (probationary), assistant engineer to the *Pembroke*, for the *Amphitrite*, to date March 13th.
Jones, C. A., to be assistant engineer R.N.R.
Larg, J. C., fleet engineer to the *Warspite*, to date March 28th.
Mabb, W. J., staff engineer, has been promoted to the rank of fleet engineer in Her Majesty's fleet.
Madge, H. A., engineer to the *Victory*, supernumerary, to date February 27th.
Madge, H. A., engineer to the *Victory*, for the *Boadicea*, to date March 13th.
Matthews, W. H., fleet engineer to the *Victory*, for the *Gibraltar*, to date March 11th.
Maxwell, J., assistant engineer to the *President*, for service at the Admiralty, to date January 14th.
Maxwell, J., assistant engineer to the *Pembroke*, for the *Shearwater*, to date March 20th.
McGregor, W., engineer to the *Victory*, for the *Hornet*, to date March 1st.
Moore, C. A., chief engineer to the *Pembroke*, for the *Brillian*, to date 13th.
Moorshead, J. E., engineer to the *Royal Arthur*, for the *Katoomba*, to date March 4th.
Morcom, W. C., engineer to the *Pembroke*, for the *Contest*, to date March 3rd.
Noll, G. W., chief engineer to the *Pembroke*, for the *Tribune*, to date March 9th.
Peel, H. C. W., chief engineer to the *Sphinx*, on recommissioning, undated.
Picton, A. L. (probationary), assistant engineer to the *Hannibal*, to date March 28th.
Raper, R. St. J., chief engineer to the *Hazard*, to date February 24th.
Ray, H. J., to be assistant engineer, R.N.R.
Read, E. W., to be assistant engineer, R.N.R.
Richards, T. W., assistant engineer to the *Britannia*, to date February 25th.
Richardson, F. M., to be assistant engineer, R.N.R.
Richardson, J., engineer, has been promoted to the rank of senior engineer, R.N.R.
Rock, H. E., assistant engineer to the *Northampton*, to date February 25th.
Roye, J. A., engineer to the *Humber*, to date March 13th.
Russell, C. E., assistant engineer to the *Royal Oak*, to date February 23rd.
Ryan, J., chief engineer to the *Pembroke*, for the *Mersey*, undated.
Shillcock, A. E. (probationary), assistant engineer to the *Royal Oak*, undated.
Short, E. A., chief engineer to the *Victory*, for the *Sharpshooter*, to date March 1st.
Sisley, G. J., assistant engineer to the *Pembroke*, for instruction in engine-room ratings, to date February 25th.
Spence, R., engineer to the *Royal Oak*, undated.
Stansmore, H. C., fleet engineer, has been placed on the Retired List, with permission to assume the rank of Inspector of Machinery.
Stevens, W. C., engineer to the *Pembroke*, for the *Bittern*, undated.
Thomas, E., fleet engineer to the *Royal Oak*, additional, to date February 23rd.
Tilbrook, C. F. H., staff engineer to the *Victory*, additional, to date March 9th.
Westmoreland, F. G., assistant engineer, to be engineer R.N.R.
Williams, H. A., to be assistant engineer R.N.R.

INDUSTRIAL AND TRADE NOTES.

THE CLYDE AND SCOTLAND.

(From our own Correspondent.)

THE falling off in fresh bookings by Clyde shipbuilders, which has been noticeable, and has been commented upon during the past two months, is now very pronounced. There have only been two or three contracts reported during March, and these have been, as will be made evident in the course of these notes, comparatively unimportant. This pause in the placing of orders is doubtless partly on account of the inability of builders and engineers to give anything like reasonable delivery, but mainly because of the high level to which prices have risen, and the advances which have had to be conceded in wages. Some owners are credited with being quite ready to place new orders, even at the high figures ruling, if they could only be assured of reasonably quick possession. As things are, however—with all the leading departments in iron, steel, coal, and with marine shops especially, at their wits' end, so to speak, in order to cope with the demands that have flowed in upon them—no assurance of delivery, except under a latitude of months, is forthcoming, and owners therefore naturally prefer to wait, uncommitted, on the course of events.

The cessation in placing orders does not of course sensibly affect the existing activity in the yards and engine shops, nor is it likely to be felt for some time to come owing to the great amount of work still on hand. Nevertheless launches are very plentiful, and the rate of output in this way is far in advance of the rate at which engineers are managing to complete the necessary machinery, in spite of working—as most of the shops are doing—double shifts. In support of this it may be stated that on the 23rd ult. it was computed that in the harbour and docks of Glasgow, from Fairfield upwards, no fewer than 30 vessels, all new, and aggregating over 60,000 tons, were afloat and being engined, or rather awaiting the completion and installation of their machinery. This is certainly a striking indication of the extraordinary brisk state of matters obtaining in Clyde engine shops.

Official intimation has just been given, by the secretary of the Clyde Engineering Employers' Association, that the employers cannot in the meantime concede the advance of wages recently asked by the men. At the meeting of the employers at which this decision was come to, held on the 22nd, the opinion was general that in the circumstances, with the price of material as well as the price of all kinds of labour so high, it would be a mistake to further increase the cost of production, more especially seeing the building berths in the yards were not being filled nearly so fast as they were being emptied. It is expected that the men will accept the decision as concluding the negotiations for the present.

For as much of the month as has passed at the time of writing, the activity in launching on the Clyde has resulted in some 20 vessels, aggregating about 45,000 tons, being consigned to their native element. This may probably be added to, and for the entire month the full tale may reach 50,000 tons, which will constitute a big month's work. To the total, however, a very substantial contribution is made by one vessel alone—the Japanese battleship *Asahi*—whose displacement tonnage when completely equipped will be as much as 15,200 tons. The launch of the ponderous vessel—she being the heaviest warship ever constructed on the Clyde—was most successfully accomplished by the staff at Clydebank, and the spectacle was witnessed by immense crowds of people. Madame Kato, the wife of the Japanese Minister in London, performed the naming ceremony. Besides smashing a bottle of wine against the bow, as the vessel began to move, a pretty Japanese launching custom was observed—a number of pigeons contained in a gaily-tinted, balloon-like cage suspended from the stern, were released, along with a shower of coloured paper, making the scene lively and picturesque.

The *Asahi*, which is the second warship built at Clydebank for the Japanese Government, closely resembles the *Shikishima* launched about four months ago by the Thames Shipbuilding Co., and is a sister ship to the *Asahi*, now building at Elswick. Her length, extreme, is 425 ft. 6 in.; breadth, 75 ft. 2½ in.; and depth, 43 ft. 7½ in. The engines, which will also be supplied by the Clydebank Co., are of the three-cylinder triple-expansion type, and consist of two sets, each of which is expected to develop 7,500 I.H.P., or a total of 15,000 I.H.P. The boilers are of the Belleville water-tube type, with economisers, and twenty-five in number. The speed will be between 18 and 19 knots. When completed, the *Asahi*, undoubtedly, will be one of the most formidable battleships afloat.

On the berth vacated by the *Asahi*, work will at once be proceeded with in laying down the keel of the *Leviathan*, which is to be the name of the armoured cruiser of the class of which three were contracted for about five weeks ago; one also being ordered from Fairfield, and the third from Barrow. These vessels are to be 500 ft. long between perpendiculars, 71 ft. breadth extreme, 26 ft. mean draught, 14,100 tons displacement, 30,000 I.H.P. speed, with natural draught, 23 knots; and are to have twin-screws and Belleville boilers with economisers.

During the month most successful trials have been gone through with a number of the 30-knot torpedo-boat destroyers, in whose successful completion Clydebank has been somewhat tardy. One of these vessels last built, the *Vulture*, on the 8th ult. made three double runs—one with and one against the tide—the mean of which was 30·70 knots. The average speed over three hours' running was 31·18 knots, with a mean I.H.P. of 6,202. The *Kestrel*, another of the Clydebank destroyers, will shortly be put through her official trials with, it is hoped, as great success as in the case of the *Vulture*. The *Leven*, one of the destroyers produced by the Fairfield Co., has also run official trials with most gratifying results. One run over the mile at Skelmorlie was made at the rate of 31·85 knots. The mean speed on three hours' trial was 30·201, the mean I.H.P. being 6,194, and the mean number of revolutions 372·4. Whilst the speed results are highly satisfactory, the result of the coal consumption is even more so, as it worked out at 2·09 lbs. per I.H.P. per hour, which is by far the best ever obtained in a boat of this class. The excellent performance is understood to be attributable to a novel fitting in the furnaces, introduced by Mr. Gracie, the engineering manager at Fairfield.

On the Clyde, as elsewhere nearer the renowned base of the fishing operations of the East Coast—viz., the Humber mouth—the trawler-building industry seems brisker than ever. Not only on the Clyde, but on the Forth, the Tay, and the Dee, these sturdy and speedy little vessels are being turned out in great numbers, and constitute no inconsiderable part of the work on hand. Messrs. Mackie & Thomson, of Govan, on the Clyde, who invariably launch three of these vessels from the same berth on one day, had, during last month as many as 10 trawlers lying within the Princes Dock, Glasgow, being supplied with their engines and deck equipment, and besides these there were three other vessels of this class, built by the Irvine Shipbuilding Co., also in dock, receiving their machinery. Messrs. Muir & Houston, of Kinning Park Engine Works, are supplying engines to the majority of this fleet of trawlers.

Messrs. Mackie & Thomson, Govan, received, about mid-month, an order to build a screw steamer 210 ft. long, and of 1,100 tons deadweight for Messrs. Hawthorn Bros. & Co., London, to be employed in the fruit-carrying trade. Engines will be supplied by Messrs. A. Stephen & Sons, Linthouse, which will be capable of driving the vessel at a speed of 11½ knots.

Messrs. Murdoch & Murray, Port-Glasgow, have contracted to build a twin-screw steamer for passenger and cargo service on the river Amazon, of a similar description to many vessels they have lately built for the same service.

The commission to build and engine a twin-screw steam yacht for the proprietor of the *New York Herald* has been given to Messrs. W. Denny & Bros., Dumbarton, by Messrs. G. L. Watson & Co., Glasgow, the noted designers for sailing and steam yachts. The new vessel will be of considerable tonnage, high speed, and have palatial accommodation. Mr. Watson's firm has recently designed for wealthy American owners, and placed with Clyde builders, several yachts of like size and character, one of which, about 1,800 tons, is now under construction in the yard of Messrs: Scott & Co., of Greenock, for Mr. A. J. Drexel, of Philadelphia. Other vessels to Mr. Watson's design and order are under way in the yard of the Ailsa Shipbuilding Co., Troon, and Messrs. Ramage & Ferguson, Leith, while only a short time has elapsed since the completion by the Fairfield Co. of Baron Rothschild's magnificent steam yacht *Atmah*. Hitherto Messrs. Denny Bros. have not done much in steam yacht building, although of course their numerous productions in the way of swift paddle-steamers for river and channel service are likely to have yielded experience which should be useful in turning out a high-class pleasure yacht of notable speed.

Messrs. Rankin & Blackmore, engineers, Greenock, have contracted to furnish triple-expansion engines for two steamers recently booked by Messrs. Russell & Co., Port-Glasgow, one set being of 2,500 I.H.P., and the other of 1,500 I.H.P.

Mr. Robert Montgomerie, engineer, Greenock, has contracted to construct two sets of engines for Messrs. Ross & Marshall, of Greenock, a firm well known in shipping circles on the Clyde through its extensive lighter and sailing business. Mr. Montgomerie has also contracted to supply engines for the steam yacht at present being built by Messrs. Blackwood & Gordon, Port-Glasgow, to the order of Mr. Joseph W. Russell, founder of the well-known shipbuilding firm of Russell & Co., of the same port.

Messrs. Ross & Marshall, above named, who have now a fleet of lighters, &c., numbering about 40, naturally find the up-keep and repair of their vessels a heavy item of expenditure, and with considerable enterprise they, about a year ago, erected a hauling-up slip as an additional facility to their building and repairing premises, immediately to the west of the shipyard of Messrs. Carmichael, Maclean & Co. The slip, which was laid down entirely by the firm's own workmen, is 600 ft. in length, and is capable of taking on vessels having a draught up to 20 ft. In addition to the slip the premises embrace accommodation and facilities connected with every department necessary in the building and repair of ships and engines. Messrs. Ross and Marshall are continually offered work by outsiders, but with their large and increasing business they find that they have quite enough to do in meeting their own needs. Amongst the vessels they have recently turned out for themselves are the *Southern Light* and the *Lucullite*. At the present time they are building a similar craft to the last-named, and are making alterations in the well-known steam launch *Medusa*, which belonged to Mr. Murray, of the *Challenger* Expedition. This vessel is being fitted with twin-screws, and otherwise fitted to take part in salvage operations.

In last month's notes reference was briefly made to the fact of bilge keels being then fitted to the Allan liner *State of Nebraska*, and it is of interest to chronicle the fact that two more instances of these important adjuncts being provided for notable transatlantic liners are furnished in the cases of the American liners *St. Louis* and *St. Paul*. On the 22nd ult. a considerable body of operatives left the Clydebank shipyard for Southampton in the large graving dock, at which port they will fit bilge keels to the first of these vessels, and eventually to the other boat.

The employees of Messrs. Hall-Brown, Buttery & Co., St. Helen's Engine Works, Govan, held their annual festival recently, completely filling the Queen's Rooms, Glasgow. Mr. E. Hall-Brown presided, and was supported by many of the Clyde shipbuilders, engineers, and marine superintendents. In presiding over such a splendid assembly, the chairman assured them, amongst other things, that he looked upon them all as real partners of the firm in the best sense of the word. The firm, it may be stated, has at present on hand a large number of sets of marine engines, amongst which is the largest order the firm have yet undertaken. This is a set of triple expansion engines of 2,500 I.H.P., intended for a steamer now being built by Messrs. R. Duncan & Co., Port Glasgow. The orders at present on hand reach the respectable total of 21, the total since the firm's inception in 1892 being 68 sets of engines. In the year stated they took over the engine works previously carried on by Mr. William Kemp. Having entirely re-organised the works, and added considerably to the plant, the output during the first year was nine engines with an I.H.P. of 1,750. Last year the output was also nine engines, but the I.H.P. rose to 12,045. Finding that their facilities for the expeditious delivery of the numerous heavy orders now entrusted to them were becoming insufficient, the firm last year erected an extension of the engine-shop, that more than doubled their floor space, and they also added a 45-ton steam travelling crane. They also built a complete range of offices, and considerably added to their staff. Mr. E. Hall-Brown, it may be added, received his engineering training in the Fairfield Engineering Works, where he was employed for nine years—the last four in the drawing office—and afterwards was with Messrs. T. Richardson & Sons, West Hartlepool, where for several years he was head of the scientific department, and was entirely responsible for the designs of all the engines turned out. This position he resigned, and joined with Mr. John A. Buttery in the present firm. Mr. Buttery is the son of Mr. John Buttery, of Penang and Singapore, and received his engineering training in the Park Locomotive Works, Glasgow.

The Grangemouth Dockyard Co., at Grangemouth on the Forth, have booked an order for, and are now laying the keel of, a four-masted sailing barquentine for Nova Scotia ownership, similar to one they built for the same owners two years ago, but of greater deadweight. The vessel will be employed in the lumber trade. This is about the only instance of a sailing ship being at present under construction in Scotland. The Dockyard Co. have also received an order from Messrs. Tatham Bromage & Co., for the repeat of a 1,100 ton steamer just finished, and which has been sold to German owners.

Speaking at the annual festival of the Dundee branch of the Boilermakers and Iron Shipbuilding Society held early in the month in the Kinnaird Hall—the largest place of assembly in Dundee, Mr. W. S. Jackson, manager of Camperdown Shipyard, who occupied the chair, referred at the outset of an interesting address to the prosperous state of the Dundee shipbuilding and boilermaking trades. At the present time, and for some little time past, both branches of industry were in a condition of exceptional activity. Wages had never been so high as now, and this showed that the workmen had the ball at their feet. They should therefore make the best of their opportunity. The existing boom, however, he feared was on the turn, and while all regretted this, they—the practical operatives in shipbuilding and boilermaking—must all admit that such good times as they had been experiencing could not be expected to last for ever. The workmen, he asserted, had had the best of the spurt, because prices had not come up with the demand, but he hoped the poor employers would get a share in the near future. Adverting to the Dundee branches of the society, Mr. Jackson said the income of the branches for the year was £1,678 3s. 11d., and the expenditure £679 16s. 10d., leaving a balance of £998 7s. 1d. He concluded by advising the men to make the best possible use of their present opportunities and lay by part of their high wages against a rainy day.

Dundee's early example of a steam engine by James Watt, till recently located at work in one of the public works of Dundee, but acquired as a memorial and example of old-time engineering by public enterprise, is now about to be housed and set up in the Barrick Building, where it will be in a situation well adapted to its preservation and to free inspection of all interested. The cost of housing and erecting the engine will amount to £500, and the fitting up will be done in such a way as to admit of electric motor power being applied for putting it in motion if at any time desired.

Mr. F. W. Paul, who has for some years been the manager of the Blochairn Works of the Steel Company of Scotland, has been appointed to a similar post at the Shelton Bar Iron and Steel Works, near Stoke-upon-Trent. Mr. Paul's experience has hitherto been connected with the making of steel by the Siemens open hearth process, but in his new post he will have to work by the Basic-Bessemer process, the raw material to be dealt with being North Staffordshire pig-iron. Before going to the Blochairn Works Mr. Paul had charge of the furnace or melting department of the Newton Works of the Steel Company. Mr. Paul has, since its foundation, been a prominent member—and latterly the President—of the West of Scotland Iron and Steel Institute. In discharging the duties of the presidentship he acquitted himself very much to his own credit and to the success of the Institute.

The unanimous re-election of Mr. T. C. Guthrie, of Messrs. Guthrie, Macdonald, Hood & Co., as representative of the Clyde Sailing Shipowners' Association on Lloyd's Register Committee until July, 1903, has given much satisfaction, not only to all interested in shipping affairs on the Clyde, but also to those who furnish materials of which ships are built. The steel makers of the West of Scotland have not forgotten that it was largely owing to Mr. Guthrie's exertions that Lloyd's Committee were enabled to find it possible to reduce the fees for the steel testing required to be done at the steel works, and this reduction has since saved the steel makers considerable sums annually.

Mr. George M. Shaw, who has been 12 years in the employ of Messrs. Ramage & Ferguson, Leith, lately as chief draughtsman in the shipyard drawing office, has been appointed to the surveying staff of Lloyd's Register. On the evening of March 1st the foreman and officials of Messrs. Ramage & Ferguson met in a social capacity, and presented Mr. Shaw with a handsome solid silver salver, bearing a suitable inscription.

The difficulty which ships' officers often experience in determining when a vessel is loaded down to her Plimsoll mark, and no more, and the troublesome, not to say vexatious, circumstances which not infrequently arise through a misjudgment as to how a vessel is situated with respect to her marks, especially where there is anything of a list, are matters which have led Mr. David Smail, of Glasgow, to devise an instrument by which accurate and ready note may be taken of the position of the water relatively to Plimsoll mark as loading proceeds. The device takes the form of a plate with a slot in the centre, and a full-sized Plimsoll marked on it, which is fixed on to the rail on deck. From it hangs a weighted float on a wire, and at the inner end there is an equal weight with an indicator. A glance at the indicator will always show accurately how the loading of a vessel is proceeding, and with it the unintentional overloading, which is a fruitful source of worry, will be impossible. With a list which often upsets calculations there could be as little chance of error, as the mean would be the true draught of the ship. The apparatus, which is cheap, portable, easily fixed, and only necessary in the later stages of loading, has been tried for six months on a vessel, and has answered admirably.

THE TYNE.

(From our own Correspondent.)

Shipbuilding.—Though shipbuilders have orders in hand sufficient to keep their machinery going throughout the year, and in some cases even for a longer period, it begins to be apparent that the tide of prosperity has reached the highest point, and that the next change will be in the direction of lessened pressure. As was stated in last month's Notes, few contracts have been placed since the advent of the new year, and now we hear that enquiries have noticeably lessened in number. This has probably been caused by the shrinkage that has taken place in rates of freight, which has served to remind shipowners that expansion is a process that cannot go on indefinitely. The reverse process is now unpleasantly obtruding itself on public notice, and hence the slight check that appears to have been given to speculative enterprise in shipbuilding. The rush of business which came to all the centres of the industry last year has had the effect of inducing firms engaged in the manufacture of steel plates and angles, as also stern frames and other forgings to enlarge their works with the view of increasing production, and in connection with the latter branch of business, several new ventures have been started. All this has been done because it was seen that existing resources were inadequate to meet the demand that had arisen. It is to be feared, however, that in many cases the developments have been made too late to admit of any large participation in the present run of prosperity, on the part of the firms concerned. It seems a truism that the best time to make extensions, or to lay down new works, is during a term of slackness, for then everything can be done at the minimum of cost, and the place is ready for operations when trade takes the upward turn which invariably succeeds depression.

Four Tynside firms have been invited by the Admiralty to tender for the construction of one or two cruisers of the *Diadem* class (440 ft. long), and we are pleased to note that among them is the enterprising firm of Messrs. C. S. Swan & Hunter, who, we believe, have not tendered for Government work hitherto, or at all events, have not executed any contracts of that description. It is much to be desired that this firm should get a share of the forthcoming work, as they have made an enviable reputation in every other department of shipbuilding, and will, no doubt—should the opportunity be afforded—make themselves an equal title to distinction in this. They possess, indeed, an advantage which no other firm in the kingdom can boast, namely, the capacity to build under cover; and in connection with the construction of warships, this ought to be a feature of very considerable importance.

Messrs. Armstrong, Whitworth & Co., are laying out new berths at their Elswick yard, and it is anticipated that in the course of the summer months, the additional building accommodation, as well as that already provided, will be fully utilised. The initiatory departments are at present very busy; but at this moment there is not much doing in the fitting out of vessels, there being only two (one of which is a Brazilian transport ship) now moored at the quay. The company's Low Walker yard continues to be full of work, all the vessels in hand being of large size, and intended for special trades. Additions to the plant are still being made, and the establishment is being brought thoroughly up-to-date as a shipbuilding yard. The company, it may be added, are amongst the firms that have been invited to tender for the new cruisers; but it is questionable whether they will avail themselves of the privilege, as they have an exceptionally large amount of mercantile work in hand, besides warships for foreign powers.

The Palmer's Co. are tendering for the Government work, and are likely to be amongst the successful competitors. The work they have hitherto turned out to the order of the Admiralty, has been most satisfactory, and as the officials of the company have special experience in this department of naval architecture, it would be strange if the company's strong claims to the favour of the Admiralty authorities, should be ignored. A very full share of mercantile work is to be seen on the stocks, however, and even if the company should fail in securing a part of the present Government programme, there is no likelihood of any lack of work taking place in their yard during the current twelve months.

Messrs. Wigham Richardson & Co. launched on the 11th ult. a very handsome steamer, ordered by the Cork Steamship Company for their Continental service. This is the fifth or *sixth time* that this prosperous Irish shipping company have come to Messrs. Wigham Richardson to get their requirements fulfilled, and the circumstance reflects much credit on this well-known firm of shipbuilders. Messrs. Hawthorn, Leslie & Co. have also launched a vessel during the month, and have another well advanced towards completion. The vessel launched was the s.s. *Kent*, a meat-boat 435 ft. long, ordered by Messrs. Wm. Milburn & Co., London. She is now at the St. Peter's Works receiving her machinery, and will soon be ready for sea. Messrs. Robert Stephenson & Co. have a fair quantity of work in hand at their Hebburn yard, and could doubtless have much more but for the circumstance that a considerable portion of their extensive yard is still occupied by the large Spanish pontoon, ordered two or three years ago, and long since completed. On account of the complications that have arisen in Spanish political affairs, however, no attempt has yet been made to disintegrate the pontoon for shipment, although it is understood that a port for its location in Spain has been selected.

The Tyne Shipbuilding Co. are still exceedingly busy, and at Messrs. Readhead's yard a full occupation of the building berths is still to be noticed. Messrs. Dobson, and Messrs. Wood & Skinner, are also well off for work, and the latter firm have just delivered to the owners, Messrs. F. Strick & Co., of London, a very fine and well-equipped cargo boat over 300 ft. in length.

In the repairing establishments business is just now exceptionally brisk, there being a large number of vessels getting overhauled, and having their equipments of auxiliary machinery &c., brought up to date. It is expected that business in the repairing line, will further improve shortly, when vessels which are usually engaged in the summer tourist service, are placed in the repairers' hands to be got ready for the coming season.

Messrs. The Smith's Dock Co., Ltd., having no room for further extensions at North Shields, have purchased a site 88 acres in extent at Jarrow Slake, which they mean to utilise, probably for the location of a pontoon dock, and the erection of necessary adjuncts in the shape of machine shops, shearlegs, &c. Jarrow Slake is a flat area between Jarrow and Tyne Dock, which is wholly covered with water at high tide, and is partially submerged at low tide. It has hitherto been largely occupied by timber rafts, and as a mooring place for vessels to be broken up; and the news that it is now to be devoted to more ambitious purposes, has caused much satisfaction at both the centres named.

Engineering.—There is a feeling in some quarters that trouble is likely to arise between the employers and the operative engineers in reference to the wages question. It is known that an advance has been asked for, though at the moment little is being said about it. No one imagines, however, that the matter is going to be dropped without an effort being made on behalf of the workmen to get the desired concession granted. There does not appear to be much discontent amongst the men as regards the wages rates, which are now at the highest point ever reached in the history of the trade, and it is shrewdly suspected that the application referred to has been put forward by a few officious leaders without the aid of any pressure from the rank and file.

The employers do not appear to have considered the matter very much as yet; but it is highly probable that should the claim for an advance be persisted in it will be refused, and the employers will doubtless be able to show good reasons for declining to give an advance under present circumstances. Meantime, work in the shops goes on very briskly, the locomotive establishments being fully as busy as the works in which marine engine building is solely carried on. As in shipbuilding, however, few new orders are being placed, and what with night shift in some departments, and overtime in others, the contracts in hand are being very rapidly got through.

Messrs. Noble & Lund, of the Felling Machine Tool Works, have numerous orders in hand for their various specialities, and great activity continues to exist in all their departments. Since the completion of their large foundry, their business has further increased, as owing to the circumstance of being able to make their own castings, they have been in a position to meet the requirements of customers with greater promptitude.

Messrs. Donkin & Co. (late Donkin & Nichol) of the St. Andrew's Engine Works, Newcastle, are well supplied with orders for steering gears, engine-room telegraphs, ash hoists, and other specialities; and in all departments of their works business continues active.

The Zynkara Co. Limited (proprietors of the well-known composition for the prevention of corrosion in boilers), continue to experience a large demand for their speciality, and we understand they are contemplating a further extension of productive resources.

The "Octopus" Lubricator Co., Limited, of which Mr. W. J. Stephens is managing director, have taken offices at No. 7 Side, where the business of the company will henceforward be carried on. This appliance is applicable to both land and marine engines, and possesses the unique quality of exactly adjusting the supply of oil to the requirements of each working part. In many other important particulars it is distinguished from other lubricating appliances, and it is significant that up to the present time 17,000 have been fitted.

Mr. George Noble, consulting engineer of 7, Dean Street, Newcastle, has appointed Mr. Joseph Johnson, 1st class engineer as his assistant. Mr. Noble, we may state, is the representative in the North Eastern counties of Messrs. Charles Cammell & Co., Sheffield.

Messrs. Isdale & Farrow, of 4, St. Nicholas Buildings, Newcastle, have been appointed sole agents in the Tyne and Wear districts for the newly-established Clydeside Tube Co., Limited, Glasgow, and have issued a circular stating that their principals are now in a position to accept orders for delivery in May. These new works cover an area of 20 acres, and are equipped in a thoroughly up-to-date manner. The managing directors are Mr. John Wotherspoon and Mr. W. S. Brown, both of whom have had a long connection with the tube-making industry.

THE WEAR.

(From our own Correspondent.)

Shipbuilding.—Messrs. Doxford launched another *Clan* steamer this month, and we believe there are two others to follow in the course of the year. One of the vessels now in the stocks is for Messrs Johnson, of Liverpool, and we are informed that the vessel ordered by the Peninsular and Oriental Company is to be put down in the berth now occupied by a vessel in the framing stage. This vessel will probably be ready for launching in May, and it may be presumed that no time will then be lost in proceeding with the laying down of the P. and O. Company's boat. We hear that another local firm of the first importance has adopted the "joggle-plating" system introduced by Messrs. Doxford some four years ago, and which has been almost as remarkable a success as their other notable invention the "turret" design. It is now pretty generally admitted that the universal adoption of this system is but a question of time.

Messrs. Short Brothers are further increasing their working facilities by the erection of a number of derrick cranes to hoist material to any part of each vessel under construction. In addition to the new work in hand, the firm are now engaged on an important repair contract.

The Sunderland Shipbuilding Company, who recently launched a finely-designed and exceptionally large vessel for Messrs. Jenkins & Co., of London, are understood to have received another order from the same owners. Their close neighbours, Messrs. Bartram & Sons, have a large vessel nearly completed for Messrs. Pinkney, Sunderland, and others in less advanced stages for owners at distant ports.

Messrs. J. L. Thompson & Sons continue to be busy on new vessels of an important class, and have also a considerable amount of repair work in hand. At Messrs. Blumer's, and also at the Strand Shipbuilding Co.'s yard, the work in progress is sufficient to keep the machinery going full.

Engineering.—The marine engine works continue to be as busy as possible, and at the smaller establishments the pressure of work is also very great. A new forge has been started at Southwick, and another establishment of the same kind is being got ready for a commencement of operations at Pallion.

The Sunderland Forge and Engineering Co., Limited, are exceedingly busy in both the electrical and forging departments. In the former there is just now in progress a contract of exceptional interest—this being the manufacture of electric motors and other accessories for Messrs. Austin & Sons, who are about to substitute electrical for steam power in driving the machinery in their shipbuilding yard. Only a limited number of shipbuilding firms have as yet adopted electricity as a motive power in their shops, but the principle is receiving more attention daily, and is evidently gaining in public favour. There is also in hand a number of contracts for electric cranes, which the firm have made a speciality; and they are besides doing a large business in ship-lighting. An important extension is now being made in connection with the forge department, this being the erection of a machinery shed which covers an extensive area, and is intended for the finishing of heavy work. A new steam hammer of the heaviest class is being put down, and other important additions to the existing plant are being made. There are at present in hand a number of exceedingly massive stern frames, ranging from 10 to 14 tons, for local firms, and one of 16 tons weight for Sir Raylton Dixon & Co., Middlesbro'. A special feature is made at this forge of the manufacture of single plate-built rudders, and a number of these are now in hand for ships in course of construction. The extensions are expected to very largely increase the productive capacity, and allow of even greater promptitude in delivery than has hitherto been attained.

The Hartlepools.—Messrs. Wm. Gray & Co. have launched a second vessel of the type known as the "Patent Side Ballast Tank," for which many advantages of an important kind are claimed. Among these may be mentioned the lessening of the tendency to roll, and the prevention of "racing" of the machinery. It remains to be seen whether the type will become popular; but in fairness, it must be said that the first vessel of this design built, has undergone the test of a rather long voyage in heavy weather, in a remarkably satisfactory manner. The whole of Messrs. Gray & Co.'s building accommodation is being utilised, and at the other Hartlepool yards business is as active as could be wished. Messrs. Richardson's engineering works are still showing great briskness, the electrical departments being as fully engaged as the older departments of the works. In the forge there are a number of important contracts in hand, and the section that has been specially set apart for the construction of auxiliary machinery, is kept in active operation. At the docks business is now quite dull, owing to the absence of timber importations. In two or three months from now, however, the state of business in the timber trade will be as brisk as ever.

Stockton.—There is still a plenitude of work in the shipyards, and at all the establishments night work in the frame-turning departments is continued. Messrs. Craig, Taylor & Co., are pushing on their important work of extension, and are ordering new plant for the equipment of the additional premises to be erected. Boilermaking establishments are extremely busy, and find it difficult to meet the requirements of customers. A new method of constructing donkey-boilers of the marine type, has come into use, which has the twofold effect of minimising labour and accelerating production. The method is to use but one plate for the circumference of the shell, thus making only one joint to be strapped and rivetted. The ends are formed of two flanged plates as hitherto, three plates forming the whole shell of the boiler. There is, we believe, no patent in the principle. and most of the boiler manufacturers are resorting to this method of construction, whenever it is permissable.

Middlesbro'.—Shipbuilding firms at this centre have their full share of work, and engineering establishments are equally well situated. Steel works are exceedingly active, and foundries, as also bridge works and boiler works, are showing a similar state of prosperity.

Darlington.—The works of the Darlington Forge Co. continue in full activity, and other works are fairly well employed.

THE MERSEY.

(From our own Correspondent.)

PRESSURE of work both on account of orders already on the books and new orders coming forward continues the report throughout all branches of the marine and general engineering and shipbuilding industries of this district. The leading machine tool makers are mostly in the position that they cannot entertain new work to be put in hand much before the close of the year, and in some exceptional cases they are compelled to decline more new orders than they are able to accept, whilst generally work is coming forward in excess of contracts running out. There is, consequently, every prospect of full activity for a considerable time ahead, and under these conditions there is a steady hardening up in prices. In all other sections of engineering the position is very much the same, locomotive builders, who have been booking a considerable weight of new work recently, having orders to carry them well over next year. Boilermakers are also exceptionally full of work, and hydraulic and electrical engineers are all excessively busy.

The monthly returns issued by the engineering trade unions continue of a very satisfactory character. The Steam Engine Makers' Society has only 1 per cent. of its total membership on donation benefit, whilst in Manchester, Bolton, and Oldham practically a clear book is reported. The difficulty with this society is, in fact, to supply men to meet the requirements of the employers, and many applications from the latter have to be declined. The United Machine Workers' Association has not more than 2¾ per cent. of the total membership on benefit, and in Manchester the proportion is under 2 per cent., whilst at Sheffield, Belfast, Gateshead, Glasgow, Barrow-in-Furness, Birkenhead, Doncaster, Huddersfield, Grantham, Halifax, Ashton-under-Lyne, Lancaster, Crewe, Gloucester, Newcastle-on-Tyne, Wigan, Edinburgh, Woolwich, Erith, Loughborough, and Grimsby there are no unemployed members. The wages question at Bolton and Blackburn, where the men have asked for an advance of 2s per week, is still pending. Out of fifty branches, twenty-nine return trade as "good," and the remainder as "fair."

On Saturday, the 11th March, Messrs. Laird Bros. floated from their building dock at Birkenhead, H.M. battleship *Glory*, which is the third warship constructed by this firm for the home navy within a period of ten years. Particulars of this vessel and its floating will be found in another column. The firm have also in hand the *Express* and *Orwell*, now undergoing their steam trials; two twin single-screw sloops, H.M.S. *Mutine* and *Rinaldo*, of 980 tons and 1,400 H.P.; a 30-knot destroyer for the Russian Government, which will shortly be ready for launching; a paddle-wheel steamer, launched in February, for the South-Eastern Railway Company's Folkestone and Boulogne traffic; a first-class battleship for H.M. Navy of 15,000 tons, and 18,000 I.H.P., to be named the *Exmouth*, is to be laid down immediately in the building dock just vacated by the *Glory*. There are also in progress a set of twin-screw engines of 15,000 H.P. for H.M.S. *Implacable*, which is building at Devonport, and a set of water-tube boilers for H.M.S. *Blanche*, to replace her original locomotive boilers.

In our last notes reference was made to the important extensions now in progress at the Manchester works of Sir William Armstrong, Whitworth & Co., Limited. These extensions, which include large additions to the ordnance department, and an entirely new range of shops for the manufacture of armour plates, are being rapidly pushed forward, and several of the shops are now in an advanced state. When completed they will be an important addition to the industrial enterprise of the district.

Messrs. B. & S. Massey, of Manchester, have recently supplied several sets of steam hammers specially designed for fastening the tyres of railway wheels after they have been put on the axle, the hammer being so constructed that they can operate between the two wheels. The firm have also just supplied to an English manufacturing firm one of the largest steam stamps which has hitherto been constructed, this being made for 20 cwt.; the largest stamps of this type previously made have not been more than 15 cwt.

An exceptionally large gas engine has just been completed by Messrs. Crossley Brothers, Limited, of Manchester. This engine is capable of giving a brake H.P. of more than 400, and is of the firm's special type. Messrs. Crossley have recently taken out a number of new patents, and have revised their designs in many ways, with the result that they have succeeded in reducing the consumption of gas in their latest patterns by more than ten per cent.

An important event during the ensuing year is the autumn meeting of the Iron and Steel Institute, which is to be held in Manchester, and as it is twelve years since the Institute last visited the above city, very considerable interest is being taken in the matter, and everything promises that the proceedings will be of a very successful character. Already a big representative local committee has been appointed, with Mr. S. R. Platt, of Oldham, as Chairman, Mr. Henry Webb, of Bury, as Vice-Chairman, and Mr. Thomas Ashbury, C.E., of Manchester, as Secretary, and the preliminary arrangements are being rapidly pushed forward.

The Railways Regulation Bill, so far as it proposes to introduce the compulsory adoption of automatic couplings, is meeting with the very strongest possible opposition from all sections of the coal trade and waggon-building industry in this district, and the contention is that this proposal has been brought forward without adequate consideration, and that even taking American statistics, where compulsory couplings are in operation, the loss of life is larger than on English railways where this arrangement has not so far been adopted.

During the past month there has been a quietening down, so far as new business is concerned, in the iron trade here. Large users are mostly well covered, and holding back from placing further orders, and transactions have been chiefly through merchants at under the current rates. Makers, however, are generally well booked, and indifferent about selling just now, and show no giving way on their basis quotations. Lancashire foundry is firm at 55s. 6d. less 2½, with Lincolnshire 53s. net, and Derbyshire 54s. to 55s. net cash delivered Manchester. Forge qualities maintain a strong tone and the general average is about 52s. 6d. less 2½ for Lancashire, and 5½ net cash for Lincolnshire, delivered Warrington. Outside brands have been very irregular, owing to the fluctuations in warrants, and the average rates show a giving way on last month's prices. Good foundry Middlesbro' ranges from about 56s. 4d. to 56s. 10d. net by rail Manchester, with Scotch iron at Manchester Docks about 59s. for Glengarnock, and 59s. 6d. for Eglinton, and ordinary foundry American pig iron about 55s. to 56s. net.

With regard to finished iron, although makers are well booked, bars are in less active request, with £6 15s. to £6 17s. 6d. the average for Lancashire, and £7 for Yorkshire and North Staffordshire qualities, delivered here. Sheets remain at about £7 15s. to £7 17s. 6d. Hoops are in steady demand at the Association list rates of £7 for random to £7 5s. for special cut lengths delivered Manchester district, and 2s. 6d. less for shipment.

The steel trade has scarcely fully maintained the strong tone recently reported. Makers still quote 69s. to 70s., less 2½, for No. 3 foundry hematites, but there has been underselling in the open market. Local made billets are quoted £5 net. In steel bars of the large sizes there have been sellers at £7 5s., with, however, general quotations £7 10s. to £7 15s. In common steel plates makers ask £7 15s. to £7 17s. 6d., but considerably under these figures has been taken in special cases. Steel boiler plates average about £8 12s. 6d. delivered in this district.

In the metal market business has been only of limited weight; and with the close of the month the downward move in raw material has been followed by a reduction in list rates for manufactured goods to the extent of ½d. per lb. on brazed brass tubes, rolled metals and wire. Delivered Manchester district basis rates are now as under:—Solid drawn brass tubes, 8¾d.; copper tubes, 11d.; brazed copper gas and steam tubes, 10¾d.; brazed brass tubes, 9¼d.; rolled brass, 7¾d.; brass wire, 8d.; copper wire, 9½d. per lb.

Business in the timber trade has been fairly satisfactory. The arrivals have been moderate, and as the deliveries of most articles have exceeded the imports, stocks, with the exception of a few items, are considerably reduced, and values steady; contracting for next season has not been brisk, but some headway has been made. The arrivals of teak squares have been very moderate; stocks are not heavy, and there is rather more enquiry, with prices firm. Planks have been coming in more freely, but there is a good demand, and stocks are not large, with values steady. There has been no importation of greenheart, but stocks are sufficient; prices are firm.

A strong healthy tone prevails in the coal trade here. The demand for house-fire qualities is keeping up exceptionally well for the time of the year, and the output is moving away, with prices firm at full list rates. Steam and forge coals are in brisk request, and strong at late quotations. At the pit mouth best Wigan Arley average 12s. to 12s. 6d.; Pemberton four ft., and seconds, Arley 10s. 6d. to 11s.; common house coal, 9s. 6d. to 10s.; and steam and forge coal, 8s. 6d. to 9s. per ton. With regard to forward contracts for gas and steam coal and locomotive fuel, it is not improbable that colliery owners will hold out for an advance of 1s. 6d. to 2s. on gas coal contracts over the rates taken last year, whilst advances of 1s. 6d. on locomotive fuel and about 1s. to 1s. 6d. per ton on steam coal contracts for shipment have been practically decided upon by local colliery owners. Engine fuel is in continued pressing demand, with rather a scarcity of supplies, and prices, which are being advanced in some cases with opening of the month, generally steady at 4s. 9d. to 5s. for common, 5s. 3d. to 5s. 9d. for medium, and 6s. to 6s. 6d. for best sorts at the pit mouth. Collieries are also holding out for a further advance on current rates for forward contracts for engine fuel.

For shipment inquiry has been fairly brisk, with ordinary steam coal fetching 9s. 6d., delivered at the Garston Docks; 10s. delivered High Level, Liverpool, and about the same figures [for delivery at the Partington tips, Manchester Ship Canal.

THAMES.

(*From our own Correspondent.*)

THE finding of the Board of Trade as a result of its investigation into the Barking explosion has now been published, and it cuts very deep since it places the whole blame on the firm. The Commissioners appointed were Mr. Howard Smith, barrister-at-law, and Mr. J. H. Hallett, consulting engineer. Mr. Gough appeared for the Board of Trade, and Mr. Digby Koe for Messrs. Hewett. Mr. Gough said the boiler was 9 ft. 6 in. in height by 10 ft. diameter, and constructed to work at a pressure of 75 lbs. per square inch. After being taken out of the precursor in 1890 it lay at Messrs. Hewett's works until 1892. It was then overhauled, repaired, and tested to 180 lbs., and then fixed to drive the works at 60 lbs. pressure. The firm owned about 180 fishing vessels, of which 28 were steamers. They did not employ a consulting engineer, and the managing director, who was not an engineer, appointed the managers of the works. Mr. Hugh Hallett, a naval architect, was manager, but he resigned in 1898, and Mr. Gordon was appointed in his place. Mr. Holt was boiler maker. Several firms supplied the works with steam gauges, and no record was kept as to whom gauges were sent for repairs, and so they were unable to ascertain when and by whom the steam gauge which was on the boiler at the time of the explosion was overhauled or tested. At Barking part of the verdict was: "The jury are of opinion that all boilers should be independently examined by a qualified inspector at stated periods, and they request the Coroner to forward this recommendation to the Board of Trade." The experts had all agreed that the explosion was due to over-pressure and greatly in excess of the 16 lbs. shown by the gauge. They concluded that one valve was loaded to 243 lbs. and the other to 257 lbs. per square inch. Mr. Howard Smith pointed out that Mr. Hallett did not possess the necessary qualifications and was unable to exercise proper supervision and control. He fixed a working pressure for the boiler which he was incompetent to fix, and he neglected to provide that a washer or ferrule was placed under each compressing nut, so as to prevent the nuts being further screwed down after the adjustment of the safety valves. It was clear the valves had not been properly adjusted in 1897, or else if the valves had been screwed down until there was only a weight of 70 lbs. on each, then 3½ turns would have produced a pressure of 180 lbs. on one and 189 lbs. on the other, instead of about 242 lbs. and 257 lbs. This fact showed what resulted from the absence of proper supervision and control. Mr. Burness, the fitter in charge, who was killed, had the qualifications and experience necessary to adjust the safety valves. Having been told to adjust a valve which had originally been set at 70 lbs., at 60 lbs. per square inch, his proper proceeding would have been to have slackened back the compression nuts, which he told Mr. Gordon he had done, instead of which he screwed them down 3½ turns when there was steam in the boiler. The Court had to state that neither Mr. R. M. Hewett, nor Mr. Donald Gordon, nor Mr. Henry Holt were to blame for the explosion, but that the firm of Messrs. Hewett and Co., Limited, were to blame for their neglect to appoint properly qualified managers for their works, which neglect conduced to the explosion, and they must be held responsible for the negligence of their servant, the late Mr. Burness, who was the direct cause of it. Messrs. Hewett & Co. had to pay half the costs of the enquiry, £125.

Another set of engines, this time for H.M.S. *Pomone*, by Messrs. John Penn & Sons have been under trial. The boilers are the same as those fitted in the sister ship *Pactolus*, and the improvements made in those were also made in those later. The first trial was with a water draught of 12 ft. forward and 15 ft. aft, and for thirty hours' coal consumption at 3,500 H.P.; the steam pressure was 242 lbs., the air pressure in the stokeholds ·88 in. of water; the engines making 173·7 and 172·6 revolutions a minute for starboard and port, and developing 1,798 and 1,811 I.H.P., or a total of 3,609; the mean vacuum was 25 in. and speed 16½ knots an hour. Consumption of coal 2·45 lbs. per I.H.P. On her eight-hour natural draught trial: steam pressure 220 lbs. per square inch; air pressure 1·4 in., and starboard and port engines making 198·3 and 203·6 revolutions per minute, the I.H.P. 5,617, the speed was 20 knots an hour. The result of her full power trial was with 252 lbs. per square in. steam pressure, and air pressure 2·77 in. with revolution 219·6 and 221 per minute, and the I.H.P. 7,340, the speed was 21·5 knots an hour. This is the record speed on a trial of this class of vessel, and it speaks well for the Blechynden boiler and Messrs. Penn & Sons' engineers.

Messrs. John Penn & Sons have also constructed the engines for H.M.S. *Goliath*. She has to have a contract speed of 18½ knots an hour. Her dimensions are: 390 ft. in length, 74 ft. beam, and loaded displacement 13,000 tons, her mean draught being 26 ft. She has twin-screws of 16 ft. 9 in. diameter, driven by two independent sets of three inverted cylinders, triple-expansion engines of 13,500 I.H.P.; the cylinders are 30 in. 49 in. and 80 in. diameter, stroke 4 ft. 3 in., piston steam valves to the high and intermediate pressure cylinders, and double-ported flat slide valves to the low pressure cylinders. Each cylinder is supported in a cast-iron column and two round forged steel columns at the front. The crank shafts are hollow steel forgings 16½ diameter in the bearings, the condenser for each engine has a cooling surface of 7,250 square feet, the circulating pumps of the centrifugal type of 3 ft. 6 in. diameter. The cylinders are steam-jacketed. The tunnel and propeller shafts are of compressed steel, and the thrust blocks have horse-shoe collars lined with white metal. The screw is four-bladed, the boss of gun-metal and the blades of manganese bronze, which are adjustable for pitches between 19 ft. and 21 ft.

There are twenty Belleville boilers, fifteen with nine elements and five of eight elements with 4½ in. tubes; each boiler has an economiser, ten of them having six and ten with seven elements of 2¾ in. tubes. The feed-water will be delivered to the boilers at temperatures ranging between 240 deg. to 250 deg. Fahr. The total grate surfaces is 1,050 square feet, and the heating surface 33,781 square feet, the working pressure being 301 lbs. per square inch, which will be reduced at the engines to 250 lbs.

BELFAST.

(*From our own Correspondent.*)

WE have but two launches from Belfast shipbuilding yards to chronicle this month. The first, which took place from Messrs. Harland & Wolff's yard on 13th March, was that of the steamer *Winifredian*, which has been built for Messrs. Frederick Leyland & Co.'s Atlantic passenger and cattle service. The new vessel is 552 ft. long by 59 ft. beam, and her gross tonnage is about 10,560. At the launching of the vessel quite an unusual ceremony at the Queen's Island took place, and accordingly more than ordinary interest was manifested on the occasion, on account of the ship being christened before leaving the ways by Miss Martin, daughter of the general manager of the company. The *Winifredian* will also be engined by her builders with triple-expansion engines of their usual type, and will be fitted throughout with electric light, as well as all the most approved appliances for expeditiously handling ship and cargo.

On the 16th of March, Messrs. Workman, Clark & Co., Limited, launched from their South yard the steel screw steamer *Brisgavia*. This vessel is 450 ft. long, 53 ft. beam, 34 ft. 5 in. depth moulded, and is classed 100 A.1. to Lloyd's requirements. She is rigged as a two-masted schooner, and has a poop, long bridge and top-gallant forecastle. The captain, officers, and engineers are accommodated in deck houses on the bridge deck, the crew being berthed forward. Her machinery will be triple-expansion engines of the most modern type, with three large steel boilers, which have been constructed at her builders' engine works, and will be fitted within the next few weeks. We understand this steamer is now the property of the Hamburg-American Co., who have purchased her from Liverpool owners, who placed the order with Messrs. Workman, Clark & Co., Limited.

We have quite a large list of casualties to chronicle in connection with the following large steamers, all of which were built at Belfast. The s.s. *Germanic*, of the White Star Line, arrived here from New York on the 17th ult., after her unfortunate accident of getting submerged at New York, she having steamed across under her own steam. She will be put in dry dock in order to have her hull cleaned, and will then undergo a thorough overhaul both internally and externally, and it is expected she will again take up her station within a few weeks.

The s.s. *Torr Head* has also been in dry dock during the past month, having the damage to her plates rectified, which it will be remembered was caused by her coming in contact with an iceberg in the Western Ocean. The repairs have been successfully carried out by the builders, Messrs. Harland & Wolff, and she has again left this port.

On the 18th of March the s.s. *China*, belonging to the Peninsular and Oriental Steam Navigation Company, arrived in Belfast Harbour. This vessel, registering as she does 7,800 tons, is one of the finest of the P. & O. fleet, and it will doubtless be remembered that on the 25th March, 1898, she ran ashore whilst on her usual run from Sydney to London with passengers and freight. So tightly was she wedged in between rocks that it was believed that her Belfast double-bottom system and the sterling work of her builders alone saved her from breaking in two. Several rocks pierced her bottom in the forepart, and her fore-holds were full of water immediately after stranding; however, salvage operations were at once commenced, but it was only after five months' hard work that the repairs necessary to make her watertight were effected. Once this was done the salvage steamers pumped her out at the rate of 14,000 tons of water per hour, and on the 17th September last she was re-floated. At Perim she underwent some more repairs, and last month commenced her homeward voyage. The sides of the *China* show some of the hardships she has come through, but the injuries she has received will be better seen after she is put in dry dock. It is said that the salvage operations for the vessel alone cost £130,000. Her builders, Messrs. Harland & Wolff, will, of course, carry out the necessary repairs.

Besides these, the *Rotterdam* and *Staterdam*, both of which vessels were recently built at the Queen's Island, have been docked and fitted with a large addition to their water-ballast capacity, as well as having some minor improvements fitted. Both these vessels have again left this port, but somehow the *Staterdam* on her outward trip ran ashore on the Antrim side of Belfast Lough, and had to return to port again to be put in dock, but the damage done being trifling, she again left on the 18th ult., for Rotterdam to load cargo.

With all these extensive repairs on hand, Messrs. Harland & Wolff will be kept exceptionally busy for some weeks, and any casual observer may see how the want of good graving dock accommodation tends to hamper important repairs, as well as preventing the taking of Government contracts by this firm. Several of these have been offered them recently, but have had to be refused owing to the want of dry dock accommodation; however, we understand that a deputation from the Belfast Harbour Trustees have again been appointed to visit the Government Officials at Whitehall, to impress upon them, if possible, the necessity of rendering assistance with the graving dock accommodation financially and otherwise, and we trust they may be successful in their mission.

We referred last month to the most successful trial trip of the new Allan Liner *Castilian*, which was built and engined by Messrs. Workman, Clark & Co., Ltd., and it is accordingly with much regret we have to now report her short and most unfortunate career, as on her return maiden voyage she got on the rocks on the Nova Scotian coast, and has now broken up and sunk in deep water, but fortunately no lives were lost by the catastrophe.

The s.s. *Parisian*, also belonging to the Allan Line, is expected here very shortly to have her engines tripled and new boilers supplied by Messrs Workman, Clark & Co., Ltd. This was erroneously stated in last month's Clyde Notes as being executed by Messrs. R. Napier & Son, Glasgow.

So far no new orders are reported to have been booked here, but there is plenty of work in hand for many months to come, although the want of material for both shipbuilding and engineering works is causing great delay in the finishing of vessels.

It may be interesting to note here that shipbuilding is about to be re-commenced in Londonderry, the Foyle Shipyard being almost ready for building. There have been many changes effected on the plant and buildings since they were taken over y the Foyle Shipbuilding Company, and in a very short time e yard will be most complete in all the necessary arrange-nts. Four long building ways have been laid out with a to executing the extensive orders promised, and the blocks have been laid on second longest ways for an order on hand. This is a steamer of 6,800 tons deadweight, to be built of steel, and for which a quantity of plates have already arrived from Glasgow. The ways laid for the steamer are much longer than any laid when the yard was previously open. Formerly the vessels were built square to the yard, and launched straight out into the river, but the ways are now all being laid at an angle to go down the fair way, which will give much more extensive launching limits, and enable the vessels to be brought up more rapidly and also more convenient to the finishing wharf. A number of minor changes in the arrangement of the yard have also been made, all of which will tend to make the operations in the various departments more easily, more economically, and more expeditiously carried out, and it is expected that within a very short time a start will be made in forging the keel of the steamer on order.

NORTH-WEST OF ENGLAND.

(From our own Correspondent.)

Barrow.—There is a growing activity in the shipbuilding and marine engineering trades of Barrow, because with every week and every month increased facilities are being provided by the extension of old premises, the building of new ones, and the utilisation of new and improved tools of every sort. The works of Vickers, Sons & Maxim, which were well equipped as the Naval Construction and Armament Co.'s works, are now much more perfect in every department, and changes are being effected on every hand whereby even greater excellence of facility will be brought into play. In addition to the ordinary up-to-date machinery produced by English and Scotch makers for shipbuilding and engineering purposes, several very clever and economic machines of American origin are being, and have already been, put down. These are doing good work, and are in very many respects really marvellous specimens of engineering skill. It speaks well for the future of Vickers' concern at Barrow that so much enterprise is being shown in this work of bringing the works up-to-date, and what is more, keeping them up-to-date, because the advantages which this policy will give will be such as will enable the firm to work profitably when less well-equipped establishments cannot pay. Some time ago it was intimated in the monthly report under this head that Vickers, Sons & Maxim had acquired a large slice of additional land by which they proposed to extend their shipbuilding department and their slip-ways. In fact, the increase of the yard will give more than double the present frontage to Walney Channel and the present launching area. A large steel-casting foundry is about to be built in the engineering department, and a new wing to the engineering shop about 1,000 ft. long by 60 ft. wide has been erected in which the work of making gun mountings will be carried on. Some very fine machinery is being put down in this department, and work has already been commenced. A very large number of orders are already in hand for the building of gun mountings for Vickers' guns, not only those required for ships building at Barrow, but for other ships and for other purposes. It is in fact very probable that this branch of engineering at the Naval Construction Works will be one of the most active. It would be difficult, however, to imagine a more active state of things than is evidenced at present in the engineering works proper, for there is not only under construction at present the engines and machinery of H.M.S. *Vengeance*, but for the first-class cruisers *Hogue*, *Euryalus*, and *King Alfred*, the name given to the improved *Powerful*, to be built at Barrow. Further than this there are the engines for the West African and Pacific boats, the engines for the Pacific Co.'s liner, and much minor work. The launch of H.M.S. *Vengeance* will probably not take place until July, but the work of both hull and engines has progressed very much and the delay in her launch will not in any sense mean any delay in the time of her completion. Ships can be launched at a very heavy weight in Barrow, not only because of the hardness of the ways on which they are built, but because of the great area and depth of water in which they are launched. Work has been commenced on two of the three first-class cruisers in course of construction, and the preliminaries for the *King Alfred* are being rapidly pushed forward. She will probably be put down on the ways from which the *Vengeance* will be launched unless another order is booked in the meantime, and then another permanent way will be made for a cruiser. Messrs. Vickers are among the firms tendering for the new first-class cruisers of high speed required to complete last year's supplementary programme. The *Amphitrite*, first-class cruiser, was delivered during last month to Chatham Dockyard, and made the voyage round the coast under easy steam very satisfactorily. She is being copper-sheathed in the dry dock, and sometime during April, will commence her speed and other trials. The first of the two West African steamers was launched at Barrow in March, and will soon be ready for sea. Her sister ship is almost ready for launching. Every effort is being made to finish the Pacific steamer *Ortona* so that she may be launched in about three months, as her owners require her to take an early position on the Pacific station. There is a big scheme on for the provision of an additional thousand houses at Barrow, chiefly for the accommodation of the workmen of Messrs. Vickers, Sons & Maxim. The scheme is not yet fully out, but it is noteworthy that the requisite land has been acquired on Walney Island near the shipyard, and that Walney is destined to become a very important adjunct to Barrow at an early date.

West Cumberland.—There is great activity in the shipbuilding industry in West Cumberland and the two yards at Maryport and Workington are fully employed, and likely to remain so for some time to come.

Shipbuilding Material.—The demand for shipbuilding materials is very steady and full, and orders are coming to hand more freely than makers can deal with them. At the Barrow Steel Works arrangements are in progress for increasing the output of plates and other materials, and there are some prospects of a steel angle mill of a modern economic type being put down. Plates are quoted at £7 2s. 6d., to £7 5s. per ton.

The Hematite Trade.—Much briskness is shown in the hematite pig-iron trade, although prices have shown many fluctuations during the past month. Makers are very steady at 60s. to 61s. for mixed Bessemer, Nos. net. f.o.b., and warrant sellers ask 59s., buyers halfpenny less net. cash. Stocks of warrant iron in hand have increased to 210,000 tons.

Shipping.—The shipping trade is fairly busy, but the returns of tonnage exports do not show up favourably compared with last year.

Reviews.

The Engineer's Year Book of Engineering Formulæ, Rules and Tables for 1899. By H. R. Kempe, A.M.Inst.C.E. London: Crosby Lockwood & Son, 1899.

Mr. Kempe, in bringing out the sixth issue of his useful publication, has afforded—in addition to the information which has been contained in his previous annuals—a large amount of new information. An interesting article for dredging has been contributed by Messrs. Flower & Everett. They give accounts of the methods of work and of the actual results attained thereby in various foreign rivers, such as the Weser, the Volga, and in certain Dutch rivers. For small works they seem to prefer the old-fashioned spoon-and-bag method to the more modern plan of operating a grab by a crane, as they contend that it gives a more level bottom instead of a number of deep holes and high ridges. In view of the increased dimensions of modern steamers and of the necessity thus laid upon harbour authorities to increase the depth of their channels, this article seems singularly opportune. Important contributions in railway matters are afforded by various writers, well qualified to speak with authority. In view of the recent disclosures as to the methods by which the late Mr. Keeley achieved the reputation of his motor, the exhaustive remarks of Mr. Unwin on the transmission of power by compressed air, will be read with unusual interest.

A Retrospect of Eight Decades. By the Rev. E. L. Berthon. London: George Bell & Sons, 1899.

To most of our readers the author of this very chatty volume is best known as the inventor of the collapsible boat which bears his name. He, however, lays claim to the parentage of far more important inventions, including no less a factor in our modern civilisation than the screw propeller. As long ago as the year 1835 he was experimenting with his *Archimedes*, a three-foot twin-screw model, on the Lake of Geneva. Having faith in this device as a propelling power, and a certain interest in naval circles, he was able to show his model at work to the Surveyor of the Navy, and from him obtained an opinion highly characteristic of the official—at all events, of that day—to the effect that "the screw was a pretty toy, which never would and never could propel a ship." Mr. Smith, who in 1838 brought the invention again to the notice of the Admiralty, arrived, as Mr. Berthon most candidly admits, at it by an entirely independent investigation; and no doubt the same could be said of the researches of M. Ericsson, the Swedish inventor, who transferred his genius to the American people. Another invention, which appears to have been entirely that of our author, was a speed indicator, which was fitted to at least two of the Royal yachts. Amongst a very large amount of discursive information, which tells us in an interesting fashion of the great changes which have taken place during her Majesty's reign, we get little glimpses of matters which will be of interest to many of our readers, such as a brief account of a trip in the old P. & O. liner *Ripon* to the Mediterranean, and a longer history of a Cape voyage in the Union liner *Spartan*. Travels in Italy and Ireland, visits to Osborne, with models of his inventions, coach rides in our own country in pre-railway times, and a good deal of pleasant chat about people met in those far-off days, make up a very entertaining volume of very light reading.

Reed's Marine Boilers, their Priming and General Management, and Notes on Water-tube Boilers. By Henry J. Davis. Second edition.

It is with no little pleasure that we take up this book for review. Mr. Reed has done so much, and has placed the marine engineers under his obligation to so large an extent with his book aids to examinations under the Board of Trade, that a fresh edition of a book on boilers is an acquisition. A book on boilers is now incomplete which leaves out of consideration the new forms of water-tube boilers. Two years ago there still remained doubts whether the water-tube boiler had come to stay. These doubts have now been completely allayed by the action of the Admiralty for the Navy, and Messrs. J. Wilson & Sons, of Hull, for the mercantile marine. The frontispiece of this book shows the trend of things in marine boiler work as well as anything else. Formerly a work on boilers would have one of the large triple-furnace multitubular boilers for frontispiece; this one has the newest form of Belleville boilers, that with the economiser on the top.

The book begins with a long paper by Mr. W. R. Grove on boiling water. In it he informs us that in proportion as water is deprived of air the character of its ebullition changes, and it becomes more like that of sulphuric acid. The author then goes on to explain circulation, but on this he only refers to that of the Scotch boiler, and does not treat of the valuable experiments made by Professor Watkinson on that of water-tube boilers. We think this a mistake. The whole economy of the water-tube boiler depends on its rapid circulation, and therefore a work which treats of water-tube boilers without going fully into the question of circulation is the play of Hamlet without the Prince of Denmark. There is an excellent table showing the estimated performances of boilers of various types compared with their steam capacity and water level area. A feature in the book is the frequent reference to original papers read at the several engineering societies. This is as it should be. It thereby ensures the book keeping abreast with current engineering thought. Feed heaters are dismissed with a page, and if we consider that they occupied so much of the attention of the Naval architects at their last session, we think that is much too little. We agree, however, with the views laid down with regard to the same. The best known types of water-tube boilers are well described, but some of the best known are entirely omitted. For example, we find Phillip's boiler but not Mr. Mumford's. Then the Durr is omitted, although thousands of horse-power have been fitted on the Continent. These are some of the errors of the book.

The book is of 223 pages and has an excellent index. The type is large and clear. Generally speaking it may be said to be a very good elementary work on boilers. It has been divided into sections. We would have preferred chapters. The figures are very good, though few of them are working drawings. We can heartily recommend it to our readers.

LAUNCHES AND TRIAL TRIPS.

LAUNCHES—English.

Boadicea.—On February 9th there was launched at Hull for the Hellyer's Steam Trawler's Co., Ltd., of Hull, an iron ketch-rigged steamer, named the *Boadicea*.

Gilderoy.—On February 10th there was launched at Bill Quay-on-Tyne, for Messrs. Ellis, Spencer & Co., Limited, of Grimsby, a steel schooner-rigged steamer of about 153 tons gross, named the *Gilderoy*.

St. Bede.—On February 11th there was launched at Sunderland for Messrs. Rankin, Gilmour & Co., of Liverpool, a steel schooner-rigged steamer of about 3,600 tons gross, named the *St. Bede*.

The Mary.—On February 11th Messrs. Hunt, Fowler & Co., Hull, launched from their yard a steel coasting steamer built to the order of Mr. W. Nettleton, of Hull. Her dimensions are:—Length, 81 ft. 6 in.; breadth, 17 ft. 9 in.; depth, 7 ft. 9 in. The engines, which are compound 25 N.H.P., will be supplied by Mr. W. M. Escreet, engineer, Burton Stather.

Assumburg.—On February 16th there was launched at Hull for the Steam Trawling Fishing Co., of Kennemerland, an iron steam ketch of about 168 tons gross, named the *Assumburg*.

Gwynwood.—On February 16th there was launched at Walker, for Messrs. Ross & Marshall, of Greenock, a steel schooner-rigged steamer, named the *Gwynwood*.

Fulmar.—On February 23rd there was launched at Hull, for Messrs. Pickering & Haldanes Steam Trawling Co., Limited, of Hull, an iron steam ketch of about 211 tons gross, named the *Fulmar*.

Akranes.—On February 24th there was launched at North Shields an iron steam ketch of about 190 tons gross, named the *Akranes*.

Sirdar.—On February 24th there was launched at North Shields for Messrs. G. Meadows, Limited, of Grimsby, an iron and steel steam ketch of about 190 tons gross, named the *Sirdar*.

Sokoto.—On February 25th Messrs. Vickers, Sons & Maxim launched from their Naval Construction Works at Barrow the first of two sister steamers building by them to the order of the British and African Steamship Co. She is a first-class passenger and cargo steamer of about 4,000 tons, built to the highest class of Lloyd's, and fitted with all the latest improvements for the African trade. She is 345 ft. long between perpendiculars, 42 ft. beam, and 25 ft. 8 in. depth moulded. Her engines are of the triple-expansion type, with cylinders of 23 in., 38 in., and 63 in. respectively, and her steam pressure is 180 lbs. The new vessel, which is named *Sokoto*, was launched by Mrs. Ella M. Dempster, daughter-in-law of Mr. John Dempster, one of the directors of the British and African Co.

King Harold.—On February 27th there was launched at Selby, by Messrs. Cochrane & Cooper, a steamship built to the order of the Viking Steam Fishing Co., of Grimsby. The vessel was named *King Harold*.

Nelson.—On February 27th there was launched by Messrs. John Jones & Sons, at Liverpool, the powerful steam tug *Nelson*, of about 150 tons gross, indicating 600 H.P., built of Siemens-Martin steel, to the highest class at Lloyd's, and will form a valuable addition to the fleet of the Alexandra Towing Co., who have ordered a duplicate vessel from the builders.

Raithmoor.—On February 27th there was launched by Messrs. John Readhead & Sons, at South Shields, the *Raithmoor*, of the following dimensions:—Length, 335 ft. overall; breadth, 47 ft.; depth, moulded, 25 ft. The vessel is of the single-deck type, with full poop aft containing cabins, and long bridge amidships, with accommodation at after-end for engineers, and topgallant forecastle for crew. The ship has been built under special survey, and classed A1 at Lloyd's. She will carry 5,130 tons deadweight on a light draught, and is fitted with all the latest improvements and appliances for the working of the vessel, and for rapid loading and discharging of cargo. The engines are of the triple-expansion type, and are constructed by Messrs. Readhead & Sons. The cylinders are 24 in., 40 in., and 64 in. by 42 in. stroke, steam being supplied by two large steel boilers, working at a pressure of 160 lbs. per square inch. The vessel has been built to the order of Messrs. Walter Runciman & Co., of Newcastle-on-Tyne and London.

Wandby.—On February 27th Messrs. Ropner & Son, Stockton-on-Tees, launched a steel screw steamer of the following dimensions, viz.:—Length between perpendiculars, 336 ft. 6 in.; breadth, extreme, 46 ft. 6 in.; depth, moulded, 27 ft. 3 in. The steamer has been built to the order of Messrs. R. Ropner & Co., West Hartlepool, and is of the three-decked rule, fitted with the builders' patent trunk, full poop, bridge, and topgallant forecastle. The saloon and cabins for captain and officers will be fitted up in the poop, the accommodation for engineers in iron houses on the bridge deck, and for the crew in the forecastle as usual. She has double bottom on the cellular principle for water ballast, and will carry about 6,000 tons on Lloyd's summer freeboard, on a light draught of water. She will have all the most recent appliances for the expeditious and economical loading and unloading of cargoes, has direct steam windlass, steam steering gear amidships, with powerful screw gear aft, six large steam winches, to which steam is supplied by two large vertical donkey boilers, stockless anchors, &c., &c. She will be fitted with a set of triple-expansion engines by Messrs. Blair & Co., Limited, having cylinders 24 in., 40 in., 66 in. by 45 in. stroke. The christening ceremony was gracefully performed by Miss Margie Ropner, of West Hartlepool, daughter of one of the managing owners, who gave her the name of *Wandby*.

Mabel Grace.—On February 28th Messrs. Laird Brothers launched at Birkenhead a steel paddle-wheel steamer, which they have built to the order of the South-Eastern and Chatham and Dover Railway Companies for their passenger traffic between Folkestone and Boulogne. The vessel has been specially designed to meet the requirements of the Channel passenger service. She has a turtle back neck forward, and a large deck-house aft, over which there is a spacious promenade deck in continuation of the bridge. She is 300 ft. long, 36 ft. beam, and measures 1,920 tons o.m. Her machinery will consist of a set of three-cylinder compound fixed diagonal engines of large power to ensure a high speed. The vessel was named *Mabel Grace*. The companies were represented by Mr. G. Kelson, consulting naval architect, and Mr. Neil Guy, superintending engineer.

Airedale.—On February 28th Messrs. Wm. Gray & Co., Limited, launched the fine steel screw steamer *Airedale*, which they have built to the order of the London and Northern Steamship Co., Limited, Messrs. Pyman Bros., London, managers. She will take Lloyd's highest class, and her dimensions are, viz.:—Length overall, 341 ft.; breadth, 47 ft.; and depth, 24 ft. 10 in. The deck erections consist of a poop, bridge and forecastle. A handsome saloon and cabins for officers, &c., are fitted up aft; the engineers' rooms are in the bridge, and the crew's accommodation forward, including a bath-room for seamen and firemen. The hull is built on the deep-frame system, with a cellular double-bottom, large hatchways, five steam winches, steam steering-gear amidships, hand-screw gear aft, two donkey boilers, patent direct steam windlass, boats on beams overhead, shifting boards throughout, stockless anchors, two telescoping masts with fore and aft rig, and a complete outfit for a first-class cargo vessel. The Central Marine Engine Works of Messrs. Wm. Gray & Co., Limited, supply the engines, which are of the triple-expansion type, having cylinders 24 in., 38 in., and 64 in. diameter, with a 42 in. piston stroke, and two large steel boilers to work at 170 lbs. pressure per square inch. The vessel has been built under the superintendence of Mr. Wm. Birchby, on behalf of the owners, and the ceremony of christening the steamer *Airedale* was gracefully performed by Miss Nellie Pyman, of West House, West Hartlepool.

Fred.—On February 28th there was launched from the yard of Messrs. R. Williamson & Son, Workington, a finely-modelled screw steamer, built to the highest class at Lloyd's, for Mr. T. G. Best, Liverpool. Her dimensions are:—Length, 140 ft.; breadth, 23 ft.; depth, moulded, 10 ft. 3½ in., and designed to carry 330 tons on Lloyd's freeboard. The engines are to be supplied by Messrs. Ross & Duncan, of Govan, and are of the compound type, having two cylinders 18 in. and 36 in., with a stroke of 24 in. As she left the ways she was gracefully named the *Fred* by Miss Best.

Rajah.—On February 28th Messrs. Cochrane & Cooper, Limited, launched from their Grovehill Shipyard, Beverley, a new steam trawler of the following dimensions:—100 ft. by 21 ft. by 11 ft. depth of hold, built to the order of Mr. Ernest Sleight, Grimsby. Engines of 45 N.P. are being supplied by

Messrs. C. D. Holmes & Co., Hull. The vessel will be completed ready for sea with all modern appliances for trawling. Mrs. G. F. Carter, of Grimsby, named the vessel s.s. *Rajah*, and after the ceremony the company adjourned to the Beverley Arms for breakfast.

Twin-Screw Steamer.—On February 28th Sir Raylton Dixon & Co., Limited, launched from their Cleveland Dockyards, Middlesbrough, a handsomely-modelled twin-screw mail and passenger steamer, built for Messrs. Elder, Dempster & Co., of Liverpool. Her principal dimensions are:—382 ft. by 46 ft. by 25 ft., moulded. Accommodation will be provided for 108 first-class and 50 second-class passengers in most spacious and handsomely fitted cabins, with large dining-room panelled in marble and inlaid wood in house on deck. The first-class smoking-room, second-class smoking-room and cabin entrances will be elaborately fitted and decorated, and the vessel will be lighted throughout with electric light. A powerful refrigerating machine with large cooling chambers will also be provided for the conveyance of fresh meat, provisions, &c. Twin-screw triple-expansion engines will be fitted by Messrs. The Wallsend Slipway and Engineering Co., Limited, Newcastle-on-Tyne, having cylinders 21½ in., 35 in., 59 in. by 42 in. stroke, supplied with steam by four large single-ended boilers working at 180 lbs. pressure, and fitted with Howden's system of forced draught.

Oceanic.—On March 1st Messrs. Cochrane & Cooper, Limited, launched from their Grovehill Shipyard, Beverley, a new steam trawler of the following dimensions:—120 ft. by 21 ft. 6 in. by 11 ft. 6 in. depth of hold. This is the largest trawler yet built, and is an addition to the fleet of Messrs. Hall, Leyman & Co., Limited, Hull. Triple-expansion engines, 70 N.P., are being supplied by Messrs. C. D. Holmes & Co, and the vessel will be completed ready for sea with the most modern appliances for trawling. Miss M. E. Wiley, of Brough, named the vessel the *Oceanic*, and after the ceremony the company adjourned to the offices of the builders for luncheon.

Onward.—On March 1st there was launched at Whitby, to the order of Messrs Joseph Constant, of London, a steam barge, named the *Onward*. Her dimensions are as follows:—Length, 130 ft.; breadth, 25 ft.; depth, moulded, 10 ft. 11 in. She will be engined by Messrs. Fay & Co., Southampton.

Rhodesia.—On March 1st Messrs. John Priestman & Co. launched at Southwick, Sunderland, a steel screw steamer 351 ft. in length, 48 ft. in breadth, and 27 ft. 4 in. depth, which has been built to the order of Messrs. John Cory & Sons, Cardiff, and will take Lloyd's highest class three-deck rule. The engines have been built by the North-Eastern Marine Engineering Co., Sunderland, and are of the triple-expansion type, with cylinders 25 in., 41 in., and 67 in., by 45 in. stroke. Two large boilers supply steam at a pressure of 160 lbs. per square inch. The vessel, during construction, has been under the supervision of Captain Couch, and was christened *Rhodesia*.

Newington.—On March 2nd there was launched at Hull by Messrs. Cook, Welton & Gemmel, a new steam trawler named the *Newington*. The vessel will be fitted with engines by Messrs C. D. Holmes & Co.

Seine.—On March 4th Messrs. William Dobson & Co. launched at Low Walker on Tyne the steel screw steamer *Seine*, which they have built to the order of the United Steamship Company, of Copenhagen. The dimensions are:—Length, 247 ft.; breadth, 34 ft.; and depth, moulded, 18 ft. 6 in. The vessel is built to the highest class of the Bureau Veritas. The engines, which are being constructed by the North-Eastern Marine Engineering Co., Limited, are of the triple-expansion type, having cylinders of 19½ in., 32½ in., and 54 in. diameter, by 36 in. stroke. Steam is supplied by two single-ended boilers working at 180 lbs. pressure.

Beaver.—On March 9th there was launched from the yard of Mr. Joseph Scarr, Grovehill, Beverley, a steel screw tug of the following dimensions:—Length overall, 80 ft.; beam, moulded, 17 ft. 6 in.; depth, moulded, 9 ft. The tug was built to the order of Joseph Constant, Esq., of London, and is to take Lloyd's highest class for tug purposes. She is built of steel throughout, and specially designed for deep sea towing, with shelter deck full length of boiler casing. On leaving the ways she was christened the *Beaver* by Miss Palmer.

Clinton.—On Friday afternoon, March 10th, Messrs. Richardson, Duck & Co. launched from their yard a steel screw steamer of the following dimensions:—Length overall, 350 ft.; breadth, extreme, 46 ft.; depth, moulded, 27 ft. 3 in. This vessel, which has been built to the order of Messrs. H. Samman & Co., of Hull, will class 100 A1 in Lloyd's Register, and has been built under special survey. She is of the three-deck type with one laid deck, with poop, bridge, and topgallant forecastle. Accommodation for captain and officers is provided in a large deck-house on bridge, engineers being berthed in bridge 'tween decks at after end, and crew in topgallant forecastle. A cellular double bottom and fore-and-aft peak tanks are fitted for water ballast. Equipment includes six steam winches, large vertical donkey boiler, steam windlass, stockless anchors, steam steering gear, &c., &c. The engines, by Messrs. Blair & Co., have cylinders 24½ in., 40½ in., and 66½ in. by 42 in. stroke, steam being supplied by two single-ended boilers having a working pressure of 160 lbs. As the vessel left the ways she was christened *Clinton* by Miss Elsie Sage, daughter of W. A. Sage, Esq., of Hull, engineer superintendent for the owners.

Clan Colquhoun.—On March 11th Messrs. W. Doxford & Sons, Limited, of Sunderland, launched the turret-deck steamer *Clan Colquhoun*, the ninth vessel of this type built for the Clan Line Steamers, Limited, of Glasgow (Cayzer, Irvine & Co.), and the 49th steamer afloat. Dimensions:—440 ft. by 51 ft. 6 in. by 32 ft.; deadweight capacity, 8,400 tons. The engines have cylinders 27½ in., 45½ in. and 75 in. by 60 in., also built by the firm. The vessel is built under British Corporation survey, highest class, and on leaving the ways was gracefully christened by Miss Portlock.

Kent.—On March 11th there was launched by Messrs. R. & W. Hawthorn, Leslie & Co., Limited, at Hebburn-on-Tyne, the large steel screw steamer *Kent*. This is the first of four sister vessels building to the order of Messrs. Wm. Milburn & Co., of London. Her principal dimensions are:—Length over all, 435 ft.; breadth, 54 ft.; depth, 40 ft. to shelter deck. The vessel has been built in excess of the highest class at Lloyd's, and is the 14th of a series of 18 vessels built and building for the Australian and New Zealand frozen meat trade. The engines have been built by Messrs. R. & W. Hawthorn, Leslie & Co., Limited, and are of the triple-expansion surface-condensing type, with cylinders of 30 in., 48 in. and 78 in. diameter, and 54 in. stroke.

Peareth.—On March 11th Messrs. Irvine's Shipuilding and Dry Docks Co., Limited, launched a handsomely-modelled steel screw steamer of 4,820 tons deadweight carrying capacity on Lloyd's summer freeboard. The vessel has been built to the order of Messrs. Beckingham & Co., Newcastle-on-Tyne, and is built to Lloyd's highest class under special survey. She is of the following dimensions:—332 ft. overall by 46 ft. extreme breadth by 23 ft. ½ in., having poop, long bridge and topgallant forecastle for the housing of the crew, cellular double bottom for water ballast, all fore and aft. The accommodation for captain, officers and engineers is provided for in houses on bridge deck, the former immediately under the navigating bridge and the latter alongside the engine casing, and cabins arranged in the latest fashion to conduce to the comfort of the officers. Special regard has been paid for dealing with rapid loading and discharge of cargoes, for which extra large hatchways have been fitted, with powerful winches of the company's own make, and double derricks to hatches, together with all the latest improvements in the entire outfit of the vessel, including steam steering gear and the latest improved steam windlass, &c. The boats will be placed on platform deck overhead. The engines are of the triple-expansion type, and will be supplied by Messrs. Sir Christopher Furness, Westgarth & Co., Limited, Middlesbrough, and are of the following dimensions: 24 in., 38 in., and 64 in. by 42 in., steam being supplied by two large single-ended boilers working at 160 lbs. As the vessel left the ways the christening ceremony was gracefully performed by Mrs. Beckingham, of Newcastle. In passing we may state that the method adopted was rather novel, a little air gun being used, the projectile being a bottle of wine, which by a very simple arrangement was shot by the lady from the platform against the vessel's bows. The hull and machinery have been built under the supervision of Mr. James Anthony, the owners' superintendent.

Jabiru.—On March 11th Messrs. Wigham Richardson & Co. launched from their Neptune Shipyard the s.s. *Jabiru*, which they are building for the Continental service of the Cork Steamship Co., of Cork. The steamer is 255 ft. in length by 33½ ft. beam, and she has very comfortable accommodation for a limited number of passengers. She will be fitted with triple-expansion engines designed to drive her at good speed, and the arrangements for working both the ship and cargo are of the most improved type. This steamer is the fourth vessel built by Messrs. Wigham Richardson & Co. for this company, and the builders have more work in hand for them. The owners were represented at the launch by Capt. Hore, of Liverpool, the marine superintendent, and by Mr. J. A. Flockhart, of Liverpool, their superintendent engineer. The christening ceremony was gracefully performed by Miss Liljquist, of Helsingfors.

Elantsobe.—On Tuesday, March 14th, Messrs. Wm. Gray & Co., Limited, launched the fine steel screw steamer *Elantsobe*. She is of the following dimensions, viz.:—Length overall, 300 ft.; breadth, 42 ft.; depth, 20 ft. 2½ in., and has been built to the order of Raman-de-la-Sota, of Bilbao. She will take Lloyd's highest class, and is of the partial awning-deck type, with the saloon and accommodation for captain and officers in the poop, the engineers' berths amidships, and the crew's quarters forward. The vessel is built on the web-frame system with cellular double bottom for water ballast, and after-peak ballast tanks, steam winches, donkey-boiler, steam steering gear amidships, screw gear aft, steam windlass, schooner rig with patent folding masts, boats on beams overhead, and generally equipped in a first-rate manner for a cargo steamer. The engines are of the triple-expansion type, working on three cranks, made by the Central Marine Engine Works of William Gray & Co., Limited. The cylinders are 23 in., 36½ in., and 62 in. diameter, and the piston stroke of 39 in., with two large steel boilers to work at a pressure of 160 lbs. per square inch. The vessel has been built under the superintendence of Captain Ricardo-de-Goicoechea, on behalf of the owners, and the ceremony of naming her *Elantsobe* was gracefully performed by Miss Ethel Harris, of Torquay.

Claudius.—On March 15th Messrs. William Gray & Co., Limited, launched the large side-ballast tank steamer *Claudius*, which they have built to the order of Mr. C. Andersen, of Hamburg. Considerable attention is now being given to the ballasting of steamers, as the exigencies of the modern shipping trade require that ships should often go long distances in stormy seas, with simple bunker coal and ballast on board. The *Claudius* is somewhat similar to the *Mancunia*, the first side-tanker which was sent out by the same builders. The performances of the *Mancunia* have been very satisfactory. She made her first voyage in water ballast, and the captain reported that for ten days after leaving the channel, in strong gales and a very heavy sea, she behaved splendidly. Racing of the machinery was reduced to a minimum, it was never necessary to stand by the throttle-valve, and there was an absence of "hammering by the sea" in the fore end of the vessel, which is usual in such circumstances. The greatest angle of rolling in a heavy beam sea was 26 degrees, or practically half of what has been experienced in other vessels. Later reports from the same vessel confirm the great utility of the side ballast tank system. The *Claudius* is built to Lloyd's highest class, her dimensions are:—Length overall, 350 ft.; breadth, 51 ft.; depth, 27 ft.; deadweight capacity, 6,200 tons. There is considerable area on deck for carrying cattle or timber, &c., and the arrangements throughout the ship, including a special outfit of steam winches, derricks, &c., will enable cargo to be dealt with most expeditiously. The cellular double bottom extends throughout the ship, and with the after peak tank will contain 1,000 tons of water ballast, while the side tanks will hold 700 tons more, a total of 1,700 tons. The side tanks extend through the main and after holds and engine-room for a length of 191 ft., in way of which the ship has double sides, adding greatly to her strength and safety also. These advantages are secured without extra material being required in the construction of the side tanks. Lower decks and other parts used in strengthening ordinary ships and which greatly impede stowage being dispensed with, and the material applied in building the side tanks. Hence the new type loses nothing as a cargo carrier. The machinery consists of a fine set of triple-expansion engines of over 1,400 H.P., with three main boilers to work at a pressure of 170 lbs. per square inch, all from the Central Marine Engine Works of the builders. Mr. P. H. Bahnsen has superintended the building of the ship on behalf of the owners, and the patent side tanks are the invention of Mr. Archibald McGlashan, chief draughtsman to the builders. The ceremony of christening the *Claudius* was gracefully performed by Miss Brydon, of Hartlepool, daughter of the general secretary of Wm. Gray & Co., Limited.

Newholm.—On March 15th there was launched from the west *shipbuilding yard of* Messrs. C. S. Swan & Hunter, Limited, Wallsend, the second of two steel screw cargo steamers, built to the order of Messrs. J. J. & C. M. Forster, of Newcastle. The principal dimensions of the vessel are:—Length overall, 341 ft.; beam, extreme, 48 ft.; and depth, moulded, 26 ft. 6 in.; and she has been built to take the highest class at Lloyd's three-deck rule with one deck laid. The accommodation for the crew is provided in a large topgallant forecastle, the saloon and captain's room being in the poop, and the officers and engineers being berthed in houses on the top of the bridge. The deadweight carrying capacity of the vessel will be about 5,500 tons on a moderate draught of water. Facilities for working this large cargo have been amply provided. Besides the usual derricks on the masts, derricks have been fitted on four derrick posts, and an ample number of winches provided. In order to ensure safety in crossing the Atlantic in winter in ballast trim, a large deep tank has been provided for water ballast, besides the water ballast in the double bottom. The engines have been built by the North Eastern Marine Engine Co., Limited, of Wallsend, and are of the triple-expansion type, having cylinders 24 in., 40 in., and 64 in. diameter by 42 in. stroke, steam being supplied by three single-ended boilers 12 ft. 9 in. diameter by 10 ft. 6 in. long, working at a pressure of 170 lbs. per square inch. On leaving the ways the steamer was gracefully named the *Newholm* by Mrs. C. M. Forster. During construction the two vessels have been under the inspection of Captain Sarah, the marine superintendent of the owners.

LAUNCHES—SCOTCH.

Elgin, Eider and Era.—On February 24th there was launched by Messrs. Mackie & Thomson, Govan, three steam trawlers of 170 tons gross each, built to the order of Messrs. Muir & Houston, for the Great Northern Steamship Fishing Co., Limited, Hull. The vessels are 103 ft. 9 in. long between perpendiculars; 21 ft. in extreme breadth; and 11 ft. 7 in. in depth (moulded). Messrs. Muir & Houston will supply triple-expansion engines for each. The *Elgin* was launched by Mrs. Cassells, Partick; the *Eider*, by Mrs. Drummond, Glasgow; and the *Era* by Miss Taggart, Glasgow.

Gorbea.—On February 24th there was successfully launched from the yard of the Campbeltown Shipbuilding Co., a steel screw steamer of 3,400 tons deadweight for a Spanish firm of shipowners. The vessel, which has been built to the highest class at Lloyd's, is intended for general trading, She will be engined by Messrs. Hutson & Son, Glasgow. On leaving the ways the steamer was named *Gorbea* by Miss Jean Martin, Marieville.

Gymeric.—Lately Messrs. Russell & Co. launched at Port Glasgow a steel screw steamer named *Gymeric*, of 6,400 tons deadweight carrying capacity, built to the order of Messrs. Andrew Weir & Co., Glasgow. Her dimensions are;—Length, 345 ft.; breadth, 49 ft. 9 in.; depth, 28 ft. 6 in.; gross tonnage, 4,000 tons, She will be supplied with triple-expansion engines by Messrs. Rankin & Blackmore.

Clan Macaulay.—On February 27th Messrs. Alex. Stephen & Sons launched at Linthouse the fifteenth steamer built by them for the Clan Line. The vessel's dimensions are 326 ft. by 40 ft. 3 in. by 26 ft. 2 in., and her displacement is about 6,150 tons. She is classed 100 A1 three-deck rule in Lloyd's, under special survey. The fittings and equipments are very complete, and are all of the most modern and approved description. The main engines have cylinders 23 in., 38 in., and 63 in. diameter respectively, by 42 in. stroke. The boilers are fitted with Howden's forced draught, and work at 200 lbs. pressure. The steamer was named *Clan Macaulay* by Mrs. Joss, wife of one of the partners of Messrs. Cayzer, Irvine & Co., the managers of the Clan Line. Messrs. Stephen have other two steamers in hand for the Clan Line.

Belvoir Castle.—On February 27th Messrs. Gourlay Brothers & Co. launched at Dundee a steam trawler which they have built for the Crampin Steam Fishing Co., Grimsby, and which was named the *Belvoir Castle*. The trawler has been built to the highest class in Lloyd's Registry and specially designed for the Iceland line fishing trade. Her principal dimensions are:—Length, 123 ft. beam, 21 ft 9 in.; depth, 12 ft.; with a gross tonnage of about 200. The engines will be of the triple-expansion type,

Aurora and Aries.—On February 28th Messrs. Ramage & Ferguson, Limited, launched two steam trawlers, which form the first vessels built for the new company, "Newhaven

Trawlers, Limited." The dimensions are 105 ft. by 20 ft. 6 in. by 11 ft. 10 in. depth, moulded, and the propelling power is supplied by triple-expansion engines, having cylinders 12 in. 19 in., and 30 in. diameter, by 21 in. stroke, steam being supplied from a large multitubular boiler working up to 180 lbs. pressure. The christening ceremonies were gracefully performed, the first trawler being named *Aurora* by Miss Graham Brown, and the second was named *Aries* by Miss McKenzie Johnston, Edinburgh. The above trawlers have been built under the superintendence of Messrs. Irwin, Atkinson, and Young, consulting engineers, Liverpool.

Birker Force.—On February 28th there was launched from the Irvine Shipbuilding and Engineering Co.'s yard at Irvine a cargo steamer, built to the order of Mr. W. S. Kennaugh, Liverpool. Her dimensions are:—165 ft. by 25 ft. by 12 ft. Engines are to be fitted by Messrs. Hutson & Sons, Glasgow, and consist of a set of compound surface-condensing engines, having cylinders 18 in. and 40 in. by 30 in. stroke, steam being supplied from a steel boiler 13 ft. 6 in. in diameter by 10 ft. 6 in long, working at a pressure of 150 lbs. The vessel is rigged as a three-masted schooner, and is well supplied with deck gear for the speedy handling of cargo As the vessel left the ways she was named *Birker Force* by Mrs. Roger, Weir Lodge, Ayr.

City of Carlisle.—On February 28th the first vessel turned out by the new shipbuilding firm of Messrs. Taylor & Mitchell, Garvel Park Slip and Dockyard, Greenock, was launched, and was named the *City of Carlisle*. She is a screw steamer of the following dimensions:—120 ft. length, 21 ft. 6 in. breadth, and 11 ft. 6 in. depth, moulded, built to the order of Mr. G. W. Bowman, of Hull. She is specially adapted for deep-sea fishing, particularly at Iceland and Greenland. She will be supplied with triple-expansion engines by Messrs. Shanks, Anderson & Co., Pollokshaws. A large company of guests assisted at the ceremony, and Mr. Peter Taylor, in responding to the toast of his firm, said they were doing their best to make a name for Garvel Park. They had a graving dock alongside which was perhaps one of the finest in the United Kingdom. He thought they were entitled, having received every consideration from the Greenock Harbour Trust, to do the best they could in the way of getting work and recouping the Harbour Trust to some extent for the consideration they had shown.

May.—Lately Messrs. Hawthorns & Co., Limited, launched the twin-screw tender *May*, built to the order of the Northern Lighthouse Board. This vessel has been built for the special purpose of supplying the gas-lit buoys on the coast, and to act as an auxiliary to the present fleet. She is fitted with all the most modern appliances, including electric light, steam steering gear, &c. As she left the ways she was christened by Mrs. Johnson.

Fantee.—On February 28th there was launched at Whiteinch by Messrs. Barclay, Curle & Co., Limited, a steel screw-steamship, built to the order of the African Steamship Co., for their Liverpool and West African trade. The vessel is classed at Lloyd's 100 A1 spar-deck rule. Her dimensions are—345 ft. by 44 ft. by 25 ft. 8 in., and measures about 3,800 tons gross. She has been specially designed for the West African trade, her carrying capacity being large on a small draught to enable her to touch at ports not accessible to other traders On deck she is fitted throughout with all the most recent and up-to-date appliances for safe and rapid loading and discharging of cargoes peculiar to the West-coast trade. The vessel is being fitted out for 70 first-class and 40 second-class passengers, her 'tween decks being designed for the carrying of troops. She is a sister ship and duplicate of the *Sobo* (s.), of which a full description was given in our launch columns, November issue, page 331. The vessel and machinery have been supervised during construction by Mr. H. J. Ward, the company's naval architect, and Mr. W. G. B. Alder, the marine engineer superintendent. The machinery, of triple-expansion type, and the boilers, are being constructed by the builders at their Finnieston works. On leaving the ways the vessel was named the *Fantee* by Mrs. Goudie, wife of Captain Goudie, the commander. The vessel was afterwards towed to the harbour to receive her machinery.

Anaxo.—On March 3rd there was launched at Port-Glasgow, by Messrs. Russell & Co., a steel spar-deck screw steamer of 4,900 tons deadweight carrying capacity, for Messrs. G. T. Soley & Co, Liverpool. Dimensions:—Length, 325 ft.; breadth, 45 ft. 6 in.; depth, 25 ft. 6 in. Messrs. Kincaid & Co., Greenock, will supply the machinery. The ceremony of naming the steamer *Anaxo* was performed by Miss Alice Lambie, Lilybank, Port-Glasgow.

Hermes.—On March 4th there was launched from the yard of the Ailsa Shipbuilding Co., Troon, a finely-modelled steel screw steamer, built to the highest class at Lloyd's for the Neptun, Dampfschifffahrts Gesellschaft, Bremen, Germany. The engines, which are triple-expansion, are being fitted by Messrs. Muir & Houston, Limited, of Glasgow. The vessel is designed to carry about 1,760 tons deadweight on Lloyd's draught, and is fitted with four powerful steam winches, windlass, and steam and hand-steering gears, and every modern convenience for the rapid loading and discharging of cargo, and for the safe navigation of the vessel. As the steamer left the ways she was gracefully named *Hermes* by Miss Margaret Wallace, Ashgrove, Ayr.

Clan Mackay.—On March 13th there was launched at St. Monans a fishing-boat, built by Mr. John Robertson, to the order of the brothers Robert, Thomas, and James Mackay, sons of Mr. Robert Mackay, Dunn, St. Monans. The new boat is 69 ft. in length, with a breadth of beam 22 ft., and was named the *Clan Mackay*.

Warfield.—On March 13th Messrs. William Hamilton & Co. launched from their Glen Yard, Port-Glasgow, a steel screw steamer of about 2,100 tons net register, and to carry 5,400 tons deadweight, for Messrs. Hickie, Borman & Co., London. The vessel has been built for the Eastern and general trade. The following are the principal dimensions:—Length, between perpendiculars, 330 ft.; breadth, 45 ft. 6 in.; depth, moulded, 26 ft. 6 in. The vessel has been built to the highest class at Lloyd's on the deep-frame system, and is fitted throughout with a double cellular bottom for water ballast, the after peak also being utilised for this. The accommodation for the officers and crew is of the most complete description, the saloon, captain's room, and two spare state rooms being in large deck house on bridge deck. The officers' and engineers' rooms are placed alongside engine casing on bridge deck, while the crew are berthed under the topgallant forecastle. The machinery, which is being supplied by Messrs. David Rowan & Son, Glasgow, is on the triple-expansion principle, the cylinders being 24 in., 40 in. and 65 in. diameter by 42 in. stroke, steam being supplied by two large boilers working at 180 lbs. pressure. As the vessel left the ways she was gracefully named the *Warfield* by Mrs. Hamilton, of Benclutha, Port-Glasgow.

Asahi.—On March 13th there was launched the Japanese battleship *Asahi* by the Clydebank Engineering & Shipbuilding Co., Glasgow, which they have built for the Japanese Government. The principal dimensions of the vessel, which weighed, as she stood on the blocks, about 7,500 tons, are:—Length, between perpendiculars, 400 ft.; length, overall, 425 ft. 6 in.; breadth, extreme, 75 ft. 2½ in.; depth, moulded, 43 ft. 7½ in.; normal mean draught of water, 27 ft. 3 in.; displacement, 15,200 tons. The armament will be entirely of Elswick design and manufacture. The ship is to be propelled by two sets of three-cylinder triple-expansion engines. Each of the sets is designed to develope 7,500 I.H.P., giving a combined I.H.P. of 15,000. Steam will be supplied by water-tube boilers of the Belleville economiser type, working at a pressure of 300 lbs., which will be reduced at the engines to 250 lbs. The coal bunkers will have a total capacity of about 1,400 tons. The launching and naming ceremony was performed by Mme. Kato, wife of the Japanese Minister.

Newport News.—On March 13th there was launched at Port-Glasgow, by Messrs. A. Rodger & Co., a steel screw steamer of the following dimensions:—Length, 314 ft.; breadth, 44 ft.; depth, 23 ft. 3 in.; gross tonnage, 2,560 tons, with a deadweight carrying capacity of 4,350 tons. Messrs. Hall-Brown, Buttery & Co. Glasgow, will supply the engines, the cylinders of which are 22½ in., 37 in., and 61 in., by 42½ in. stroke. The vessel was named *Newport News* and is built to the order of Messrs. Furness, Withy & Co., West Hartlepool.

Paragon.—On March 14th there was launched at Aberdeen by Messrs. Alexander Hall & Co., a steam trawler, built to the order of Messrs. Laverack & Stephenson, Hull. The vessel is 115 ft. in length, 21 ft. in breadth, and 11 ft. 6 in. in depth of hold. She will be fitted with triple-expansion engines, and was named the *Paragon*.

Valetta.—On March 15th there was launched from the yard of Messrs. Murdoch & Murray, Port Glasgow, a steel screw steamer for Messrs. Gow, Harrison & Co., Glasgow. The dimensions are: — Length, 320 ft.; breadth, 46 ft.; depth, moulded, 23 ft. 9 in. The vessel is built to Lloyd's highest class and is designed to carry about 4,700 tons on a comparatively light draught. The erections are, a poop, long bridge and topgallant forecastle, the crew being berthed in the latter, whilst the saloon, officers' and engineers' rooms, etc., are placed in houses in top of bridge deck. Six steam winches, and eight derricks form the discharging gear, for four large hatches. The vessel is also fitted with a powerful steam windlass, and steam steering gear, the latter being placed near the engine-room with controlling shafting to bridge. The machinery consists of triple-expansion engines having cylinders 22½ in., 36½ in., and 60 in., by 42 in. stroke, with steam at 180 lbs. pressure, supplied from one large boiler fitted with Howden's forced draught. The ceremony of naming the ship *Valetta* was gracefully performed by Miss Clark, Montgomerie Crescent, Kelvinside. After the launch the vessel was taken to Glasgow, where Messrs. Hall-Brown, Buttery & Co. will supply the machinery. The ship and machinery have been superintended during construction by Mr. Geo. Macfarlane, M.I.N.A., Glasgow.

Maidstone.—On March 15th there was launched by Messrs. William Denny & Bros. from their yard at Dumbarton, a steel screw steamer, built by them for the South-Eastern and Chatham and Dover Railway Co.'s service between Dover and Calais. The moulded dimensions are:—195 ft. by 28 ft. by 15 ft. She has been specially designed for this service, the builders being assisted in the arrangement of details by Captain Dixon and Mr. Messenger, the company's superintendents at Dover. She has a straight stem and elliptical stern. The bottom throughout, except under machinery, is on the cellular principle, and the peaks are also adapted for carrying water for trimming purposes. She has two pole masts. The officers are berthed on the lower deck aft, and the crew in side-houses inside the forecastle. Horse stalls are fitted in the bridge and in the after-hold. She is lighted throughout, holds included, with electric light. The engines are of the three-cylinder triple-expansion type, and, with the two boilers, have been supplied by Denny & Co. The christening ceremony of naming the vessel *Maidstone* was performed by Miss Eva Ward, daughter of Mr. John Ward, one of the partners of the firm of Messrs. William Denny & Bros.

Scandinavia.—On March 16th there was launched by Messrs. Carmichael, Maclean & Co., at Greenock, a handsomely-modelled steel screw steamer, to the order of Messrs. Svneska Lloyds. The vessel has been designed to carry a deadweight of about 1,800 tons, and has accommodation under poop for crew and on bridge for passengers, captain, and officers, and will be furnished with all modern appliances for the quick working of cargo. The vessel has been built with a view of adaptability for general trade, and also for carrying a deck cargo of wood when required. The dimensions of the vessel are:—239 ft. 4 in. by 35 ft. by 17 ft. 9 in. moulded to main deck; gross tonnage, about 1,250 tons. She has been constructed to the highest class at Lloyd's and the requirements of the Swedish law. The engines will be supplied by Messrs. Muir & Houston, Limited, of Glasgow. The ceremony of naming the vessel the *Scandinavia* was performed by Miss Ruth Maclean, Dowanhill, Glasgow.

Poulton.—On March 17th Messrs. Fleming & Ferguson, Limited, Paisley, launched from their yard the powerful twin-screw pump hopper dredger *Poulton*, built to the joint order of the Lancashire & Yorkshire & London & North-Western Railway Companies, and is intended for clearing the Fleetwood Bar. The vessel has been built to Lloyd's highest class. The christening ceremony was performed by Miss Bayley, daughter of Mr. C. W. Bayley, secretary of the Lancashire and Yorkshire Railway Co.

Texas.—On March 16th Messrs. Charles Connell & Co. launched, at Scotstown, the steel screw-steamer *Texas*, to the order of Messrs. Robert Mackill & Co., for the United Steamship Co. of Copenhagen. Her dimensions are:—Length, 375 ft.; breadth, 50 ft.; depth, 28 ft. 8 in. moulded; with a deadweight capacity of about 7,000 tons. She has been built to Lloyd's highest class, with a cellular double bottom right fore and aft for water ballast. The engines, which are of the most approved triple-expansion type, have cylinders 25 in., 41 in., and 67 in by 48 stroke, worked by two single-ended boilers, and are being *constructed by Messrs.* David Rowan & Son, Glasgow.

LAUNCH—IRISH.

Winifredian.—On March 11th a large screw steamer was launched by Messrs. Harland & Wolff, at Belfast, for Messrs. Frederick Leyland & Co.'s Atlantic cargo, cattle, and passenger service. The vessel is 552 ft. long by 59 ft. beam, and with about 10,560 of a gross tonnage. She will have triple-expansion engines, constructed by the builders, and will be fitted with electric light, and have all the most modern appliances for working ship and cargo. The ceremony of naming the vessel the *Winifredian* was performed by Miss Martin, daughter of the general manager of the line.

LAUNCH—GERMAN.

Secunda.—On March 7th the Flensburg Shipbuilding Co. launched from their shipbuilding yard at Flensburg, a new steel screw cargo steamer they are building for the Flensburger Dampfschifffahrt Gesellschaft vor 1869. The vessel is 270 ft. between perpendiculars by 39 ft. beam by 18 ft. 2 in. moulded depth, built to German Lloyd's 100 A, and is to carry about 3,000 tons. Accommodation for the officers is contained in a steel house built on top of bridge deck amidships, the crew being berthed in forecastle. She is a partial awning deck boat fitted with steam windlass, steam capstan, steam steering gear and four powerful steam winches. The engines being supplied by the Flensburg Shipbuilding Co., are of the triple-expansion type with cylinders 19 in., 31½ in., 51 in., by 36 in. stroke. The vessel was christened *Secunda* by Miss Clothilde Danielseu.

TRIAL TRIPS.

Pendeen.—On February 23rd Messrs. William Gray & Co., Limited, sent to sea for her trial trip the s.s. *Pendeen*, which is the fifth vessel they have built and engined to the order of Mr. R. B. Chellew, of Truro (of which we gave full particulars in our launch columns, December issue, page 371). A very satisfactory run was made, the vessel on its conclusion proceeding to Venice to load.

Inchmaree.—On February 23rd this vessel (one of the fleet of Messrs. Hamilton, Fraser & Co., of Liverpool) also left the port after undergoing extensive overhaul and renewal of some parts of the machinery at the hands of William Gray & Co. Everything passed off very satisfactorily.

Woodford.—On Thursday, February 23rd, the s.s. *Woodford*, built by Messrs. Ropner & Son, of Stockton-on-Tees, to the order of the Britain Steamship Co., London (of which we gave full particulars in our columns, February issue, page 473), made her trial trip in the Tees Bay, which was quite satisfactory in every way, and the day being exceptionally fine, the trip proved very enjoyable to the visitors and others on board. The owners were represented by Mr. James Spence, under whose supervision the steamer has been built, whilst the builders were represented by Mr. Leonard Ropner. After adjustment of compasses, the steamer proceeded on her run round to Cardiff, where she will load.

Cardiganshire.—On February 25th the new screw steamer *Cardiganshire*, being the third vessel built to the order of Messrs. Jenkins & Co., Limited, of London, for their Shire Line of steamers, by the Sunderland Shipbuilding Co., Limited (of which we gave full particulars in our launch columns, March issue, page 512), was taken to sea for her official trial trip, and was in every way most satisfactory, a mean speed of 11½ knots being obtained on the measured mile, after which the vessel left for Middlesbro', where she takes in the first portion of her cargo for Japan.

Claverdale.—On February 25th the s.s. *Claverdale*, built by Messrs. Craig, Taylor & Co., Stockton-on-Tees, for Messrs. Edmund Haslehust & Co., of London (of which we gave full particulars in our launch columns, January issue, page 429), proceeded to sea for her trial trip. Throughout the whole of the trip the engines worked with the greatest smoothness, and on the run from the Tees to the Tyne a speed of 11½ knots was maintained. Mr. Hewlett, of the firm of Messrs. E. Haslehust & Co., expressed himself as being highly pleased with both the hull and engines, as also did Mr. Barringer, of the firm of Messrs. Jacobs & Barringer, the consulting engineers of the owners. Captain John Barker, who has superintended the construction of the hull and outfit, has taken command of the vessel, which was taken into Tyne Dock to load for Genoa.

Newcastle.—On February 25th the s.s. *Newcastle*, which has been built by C. S. Swan & Hunter, Limited, to the order of the Newcastle Steamship Co., Limited, of Newcastle, managed by J. J. & C. M. Forster (of which we gave full particulars in our launch columns, February issue, page 475), was taken out to sea for her trial trip. A mean speed of 10½ knots was attained on the measured mile, which was considered highly satisfactory, after which the vessel was taken into Blyth, where she loaded her first cargo, and sailed the following week for Alexandria.

Saint Kilda.—On February 25th the new steel screw steamer *Saint Kilda*, built by Messrs. Archd. McMillan & Son, Limited, Dumbarton, for Messrs. Rankin, Gilmour & Co., Liverpool, went down the Firth of Clyde on her trial trip. The dimensions of the vessel are 340 ft. by 45 ft. by 28 ft. 9 in., and the machinery has been supplied by Messrs. D. Rowan & Son, Glasgow. On the completion of the trial, which was in every way satisfactory, the vessel proceeded to Barry, where she is to road.

Silesia.—On February 25th the s.s. *Silesia*, which has been built by Messrs. Wigham Richardson & Co., at their Neptune Works, Newcastle-on-Tyne, for the Austrian Lloyd's Steam Navigation Co., Trieste (of which we gave full particulars in our launch columns, January issue, page 428), having very successfully completed her trials, sailed from the Tyne for Venice. On the trials the owners were represented by Mr. Smith, as well as by Mr. Vecchi, under whose superintendence the vessel, with her engines and boilers, has been built. The *Silesia* is commanded by Capt. Mayer, one of the most experienced captains in the Austrian Lloyd fleet.

Bardsey.—Lately the steamship *Bardsey*, built by Messrs. Richardson, Duck & Co., for Messrs. Farrar, Groves & Co., of London (of which we gave full particulars in our launch columns, March issue, page 513), had her trial trip. The vessel attained a speed of 11½ knots per hour, and this result, together with the whole arrangements of the vessel, met with the approval of the owners. The *Bardsey* has a deadweight carrying capacity of 5,800 tons.

Derwen.—Lately the new screw steamer *Derwen*, built by Messrs. John Readhead & Sons, West Docks, South Shields, to the order of Messrs. W. H. & C. T. Jones, Cardiff (of which we gave full particulars in our launch columns, February issue, page 476), has been to sea on her official trial trip.

Feronia.—On February 25th the s.s. *Feronia*, built by Messrs. W. Harkess & Son, of Middlesbrough, to the order of Messrs. Pile & Co., of London (of which we gave particulars in our launch columns, February issue, page 476), went out on trial from the Tees. The engines, which are of the triple-expansion type, have cylinders 14 in., 22½ in., and 37 in. diameter by 27 in. stroke. Steam is supplied by one extra large steel boiler, also constructed by the builders, to pass Lloyd's special survey and German law requirements for a working pressure of 160 lbs. per square inch. After adjusting compasses the vessel headed north, the passage between Hartlepool and the Tyne being accomplished at a speed of about 10½ knots.

Raithwaite —On March 2nd the large steel screw steamer *Raithwaite* had her trial trip in Hartlepool Bay. She has been built by Messrs. Wm. Gray & Co., Limited, of West Hartlepool, to the order of Messrs. The Pyman Steamship Co., Limited, of West Hartlepool (of which we gave full particulars in our launch columns, March issue, page 512). The vessel went out about six a.m., and after adjustment of compasses by Mr. Berry, was manœuvred to test her capabilities. Her speed, as registered by the patent log, was about 12 knots, and her performance in every respect highly satisfactory. The owners were represented by Mr. T. W. Smyth and Mr. W. Cromar, the shipyard by Captain Murrell, and the engine works by Mr. W. C. Borrowman. The vessel proceeds to Cardiff to load for Colombo.

Gertrud.—On March 4th the new cargo and passenger steamer *Gertrud* run a very successful trial trip in the Flensburg Bay. The *Gertrud* has been built by the Flensburg Shipbuilding Co., to the order of the Neue Dampfer Compagnie, in Stettin. She is a duplicate of the s.s. *Elsa*, and intended for the Baltic trade. The principal dimensions are:—Length, overall, 208 ft.; breadth, extreme, 29 ft.; depth, moulded, 14 ft. 1 in.; classed at German Lloyd's 100 A, and carries about 800 tons. She has been fitted with passenger arrangement below deck, officers' berths above bridge, and crew space in topgallant forecastle. Steam windlass and steam winches and De Voss patent lowering gear for lifeboats is arranged on bridge deck. The engines have been built by the Flensburg Shipbuilding Engineering Department, and are of the compound type, with cylinders 23 in. and 42 in. by 27 in. stroke. They worked very smoothly throughout the trial, and gave the vessel a speed of 10 knots.

Spithead.—On March 7th the screw steamer *Spithead*, built by the London and Glasgow Engineering and Shipbuilding Co., Limited, for the Clyde Shipping Co.'s ocean-going fleet (of which we gave full particulars in our launch columns, March issue, page 516), proceeded down the river on her trial trip, when everything worked most satisfactorily, and the vessel proceeded the same afternoon for Cardiff to load for the East.

Bardistan.—On March 9th this vessel had a very successful trial trip. She is a fine steel screw steamer 285 ft. in length, 41 ft. 6 in. in breadth, and 20 ft. 2 in. in depth, and is the seventh vessel built by Messrs. Wm. Gray & Co., Ltd., West Hartlepool, to the order of Messrs. Frank C. Strick & Co., Ltd., of Swansea and London. She has been built to Lloyd's highest class. Her deck erections consist of poop, raised quarter deck, bridge, and topgallant forecastle. The saloon and accommodation for captain and officers are fitted in the poop, the engineers' berths are amidships, and the crew's quarters forward. The vessel is built with bulb-angle frames, cellular double bottom, and after-peak ballast tanks, steam winches, patent donkey boiler, steam steering gear amidships, screw gear aft, steam windlass, schooner rig with telescoping masts, boats on beams overhead, etc. The engines are of the triple-expansion type, supplied by the Central Marine Engine works of Wm. Gray & Co., Limited, and have cylinders 21½ in., 34 in., and 57 in. diameter, with a piston stroke of 39 inch. There are two steel boilers working at a pressure of 160 lbs. per sq. inch. The vessel went out about noon, and after being manœuvred to the requirements of Mr. Berry for the purpose of adjusting compasses, was tested for speed, etc., her average performance with the log overboard being about 10½ knots. The owners were represented by Mr. Hay, assistant inspecting engineer to the firm, the shipbuilders by Captain Murrell, and the engine builders by Mr. W. C. Borrowman. The vessel proceeds to Barry to load for Algiers.

Degama.—On March 10th the fine steel screw steamer *Degama* proceeded on her official trial trip in Hartlepool Bay with a large number of visitors and officials on board. The vessel has been built by Messrs. Furness, Withy & Co., Limited, to the order of Messrs. Elder, Dempster & Co., of Liverpool, (of which we gave full particulars in our launch columns, February issue, page 475). The engines ran very smoothly during the trial, and the vessel attained a speed of 11½ knots. Mr. T. H. Smith represented the owners, and Mr. G. W. Sivewright the builders. After the trial the vessel proceeded to the Tyne.

Kum Sang.—On Saturday, March 11th, the fine steel screw steamer *Kum Sang*, built by Sir Raylton Dixon & Co., Limited, Cleveland Dockyards, Middlesbrough, to the order of Messrs. The Indo-China Steam Navigation Co., Limited, of London (of which we gave full particulars in our launch columns, February issue, page 476), was taken out to sea under the command of Captain J. M. Hay, for her official trials. Mr. Cheyne, secretary of the Indo-China Steam Navigation Co., Mr. Roberts the superintendent engineer, and Mr. Barrett, resident inspector for the company, were on board during the trials which passed off most successfully, and the vessel afterwards proceeded to Blyth to load.

Solo.—On March 11th the steamer *Solo*, which has been built by Messrs. Wigham Richardson & Co., to the order of the Rotterdamsche Lloyd of Rotterdam, went for a very successful trial trip off the mouth of the river. The *Solo* is built of steel, to the highest class in the Registry of the Bureau Veritas. She is 333 ft. long by 44 ft. beam, is rigged as a two-masted schooner, and has very comfortable accommodation for a limited number of passengers. During the trial the machinery worked without the slightest hitch, giving satisfaction to all concerned. The owners were represented on the trial trip by Mr. W. Ruys, head of the firm of W. Ruys & Sons, managers of the Rotterdamsche Lloyd, and there were also present Mr. A. Ruys, Mr. J. de Bruyn Kops, naval architect, of the Hague, under whose superintendence the steamer has been built, and Mr. Atkins, of Rotterdam, who superintended the construction of the engines and boiler. After the trial the steamer sailed for Rotterdam under the command of Capt. Engelsman.

Muristan.—On March 14th the new steel screw steamer *Muristan*, which has been built by Messrs. Wood, Skinner & Co., Limited, Bill Quay-on-Tyne, to the order of Messrs. F. C. Strick & Co., London (of which we gave full particulars in our launch columns, February issue, page 474), left the Tyne for her official trip, during which the machinery worked without a hitch, and gave every satisfaction to the company on board, which included Mr. Martin, representing the owners, and Mr. J. S. Wood the shipbuilders, Mr. S. Hunter for the engine builders, and Mr. A. Walker, of London, who, assisted by Mr. Hay, has superintended the construction of both ship and machinery. After the trial the vessel proceeded on her voyage to London, where she will load her first cargo.

Anna.—On Wednesday, March 15th, the steel screw steamer *Anna* left Messrs. Craig, Taylor & Co.'s shipbuilding yard, Thornaby-on-Tees, for her trial trip, which proved highly satisfactory. The leading dimensions are 299 ft. by 43 ft. 2 in., by 21 ft. 3 in. depth, moulded. She is of the single-deck type, to Lloyd's highest class, and is constructed to carry about 3,550 tons deadweight on a light draught of water. The captain's, officers', and engineers' accommodation is all placed amidships, the crew being in the forecastle. She is fitted with deep frames throughout, and has large cubic capacity; also water ballast fore and aft, and in peaks. The deck machinery consists of four large steam winches, steam windlass, steam steering gear, large donkey-boiler, screw gear aft, &c. She is rigged as a fore-and-aft schooner, with telescopic masts, and is also supplied with stockless anchors, &c. The engines, which were by Messrs. T. Richardson & Son, Limited, of Hartlepool, are of the following size, viz., 22 in., 35 in., 59 in. by 39 in., with two large boilers. During the whole of the trip they worked without the slightest hitch, running with the greatest smoothness, and a speed of twelve knots was maintained. The vessel has been built for Messrs. Fratelli Cosulich & Co., of Trieste, who were represented on the trial trip by Mr. Callisto Cosulich, this gentleman expressing himself as being highly pleased with both the ship and engines. The vessel afterwards left for Hamburg, under the command of Captain Antonio N. Cosulich. She will load in Hamburg for the far East.

H.M.S. Kestrel.—On March 15th and 17th the Clydebank Engineering and Shipbuilding Co. successfully carried out the trials of the the torpedo-boa destroyer *Kestrel*. On the 15th the *Kestrel* went for the official coal-consumption trial at full speed for three hours, and on the 17th the official full-speed trial took place. Six runs were made on the measured mile at Skelmorlie, giving a mean speed of 30·406 knots. The vessel subsequently completed the three-hours trial, which finished near Skelmorlie at 3.15 p.m. After the speed trial, stopping, starting, and steering trials were made. The Admiralty were represented by Messrs. Welch & Wisnom, overseers, and officials from Portsmouth Dockyard were also on board.

Ludvig Peyron.—On March 17th the s.s. *Ludvig Peyron*, built by Messrs. Carmichael, Maclean & Co., Greenock, for the Stockholm Company (of which we gave full particulars in our launch columns, December issue, page 374), went on her trial trip on the Clyde, and attained a mean speed of 9½ knots, with 1,700 tons of cargo on board, on 16 ft. draught. The coal consumption was 1·43 lbs. per I.H.P., which was considered highly satisfactory by the owners' representatives. Messrs. Muir & Houston, Limited, of Glasgow, supplied the vessel with triple-expansion engines, cylinders of 18 in., 30 in., and 48 in. by 33 in. stroke.

Correspondence.

[*We do not in any way pledge ourselves to the opinions preferred under this heading.*]

SPEEDS AND COAL ENDURANCE.

To the Editor of THE MARINE ENGINEER.

DEAR SIR,—With reference to the statement in your article on the new *Oceanic* in your last issue, that she and the *Teutonic* have the largest coal endurances in the world, I have seen it *stated elsewhere that* the Orient Line s.s. *Ophir* and *Omrah* *could keep the sea without recoaling for periods* of 130 and 150 days respectively at a cruising speed of 10 knots per hour. Would you kindly inform me whether this is so? Though not a marine engineer by profession, I take a great interest in matters maritime, and I am indebted to your paper for much valuable information concerning shipping.

Could you inform me what ship holds the record (*a*) for a passage and mail delivery from Plymouth to Adelaide; (*b*) for a passage from Adelaide to Plymouth?

I *believe* the *Ophir* of the Orient Line holds the outward *mail* record with 24 days 2 hours, but have no certain information as to the passage from Adelaide to Plymouth.

I notice the new steamer *Omrah* of the same line has just made a good run from Suez to Perim. Leaving the Canal at 10 a.m. on Friday last, she passed Perim yesterday at 1 p.m. *i.e.*, 3 days 3 hours for a distance of 1,211 miles, making an average speed of 16·146 knots per hour! Is this also a record? If not, at least it is considerably faster than the usual rate of progress in these waters, which is usually about 14 knots an hour.

I see the *China* has just left Port Said for Belfast, where, I suppose, Messrs. Harland & Wolff will repair her, but I presume she will not take her place in the P. & O. fleet again, as a mail boat?

Apologising for troubling you, and thanking you in anticipation,

I am, sir,
Yours faithfully,
S. L. BROAD.

Old Christchurch Road,
Bournemouth East,
February 21st, 1899.

Our correspondent asks a number of questions, most of which it is practically impossible to answer, we fear. The *China* has been temporarily repaired afloat at Perim, and only reached Belfast on the 18th March. Till she has been dry-docked and thoroughly examined by the builders and experts it is impossible for even her owners to answer the question as to her future. The question as to the mail record between Adelaide and Plymouth is not one that could be easily answered, for the vessels of the Australian lines do not go fast after they have discharged their mails on the homeward run at the Mediterranean port or before they have shipped them there on the outward trip. The fair test is the run to the mail port in the Mediterranean, or the time of mail transit to London. Each new ship when she comes out usually makes a run to show her paces, and then subsides into a jog trot, merely keeping her contract time and easing down if she is getting ahead of her time. As regards the coal endurance question, the statements published concerning the *Oceanic* and the *Teutonic* and the *Ophir* and *Omrah* are merely owners' and builders' statements. It is impossible for an outsider to check them. Only those well acquainted with the vessel know what her consumption at cruising speed would be per diem. Then, even if he knew that, he could not find out how much extra bunker space is reckoned in the provision for this long sea keeping. It is, however, probable that the *Oceanic*, whose cruising speed will be higher than that of the other ships named, will certainly have the greatest coal endurance.—ED. M.E.

Miscellaneous.

Catalogue.—We have just received a new illustrated catalogue which has been issued by Messrs. Fleming, Birkly & Goodall, Limited, of West Grove Mill, Halifax, and 39, Lime Street, London, E.C., which gives full particulars with reference to the large assortment of goods which they manufacture and supply. These comprise practically all the types and sorts of belting upon the market, and the various fastening devices for same, and apparatus for stretching the belts when making the joints. All the usual forms of hydraulic leathers, various washers of different materials, and delivery hose and fire appliances are listed. And, lastly, we would refer to steam and other packing, which is illustrated and fully described in this catalogue. It is in a convenient form and of a handy size for ready reference, which is a useful characteristic.

We understand that Messrs. Thos. Firth & Sons, Limited, Sheffield, the well-known firm of steel manufacturers, have appointed Messrs. Echalay, Laith & Co., of Newcastle-on-Tyne, to be sole agents in the North-East Coast district for all their manufactures.

Ventilation of Ships.—An interesting test of a 30 in. electric Blackman fan has been made on board one of the Laird Line steamers. The *modus operandi* was as follows:—All the openings in the hold were closed, and two heaps of refuse ignited for the purpose of filling the space with smoke. This, in a short time, got so dense that the electric lights were invisible at a distance of 20 ft. The fan was then set in motion, and in less than three minutes the atmosphere in the hold was perfectly clear, thus demonstrating that the whole of the air had been renewed in that short period of time. Since the experiment above described was made the following observations, which are worthy of note, have been taken in connection with a 16-hours' voyage. There were 110 head of cattle stowed in the hold, this being the full number allowed, and during the entire passage the thermometer never registered more than 60 deg. Owing to the vapour given off by the cattle being removed by the fans as quickly as produced it was possible to see from one end to the other during the whole of the time. The temperature before the cattle were taken on board was 50 deg. The directors of the Laird Line are so pleased with these results that orders have been placed for fans for the ventilation of the holds of some other vessels of their fleet. These are being fitted up under the superintendence of the engineers of the Blackman Ventilating Co., Limited, 162, Hope Street, Glasgow.

Wailes, Dove & Co. was registered on March 9th with a capital of £38,000, in £1 shares (15,000·5 per cent. cumulative preference), to acquire and take over as going concerns, and carry on the business of a manufacturer of enamels, solutions, tank-top coverings, cement, paints, and compositions for the protection of steel and iron now carried on by Edward J. Dove at Newcastle-upon-Tyne as "Wailes, Dove & Co."; also of the business of a marine surveyor and naval architect now carried on by Edward Dove at Newcastle-upon-Tyne as "E. F. Wailes & Co." The subscribers are:—Edwd. J. Dove, Greystoke, Grainger Park Road, Newcastle, manufacturer; Mrs. Mary C. Dove, Greystoke, Grainger Park Road, Newcastle; Mrs. Mary W. Dove, High Park, Newcastle; David N. Brims, Spring Bank, Benwell, Newcastle, contractor; Chas. Macdonald, Brodrick Street, South Shields, naval architect; Jas. E. Muir, Derby Crescent, Kelvinside, Glasgow, engineer; Percy Hedley Chirton, Clifton Road, Newcastle, gentleman. The number of directors is not to be less than three nor more than five; the first are Edwd. J. Dove, David N. Brims, Chas. Macdonald, and Jas. E. Muir; qualification, £500; remuneration as fixed by the company. The company is a semi-private one, a few prospectuses only being sent out to friends and customers of the firm.

Shipbuilding at Campbeltown—Though Campbeltown, on the East coast of the long peninsula of Kintyre in Western Scotland—of which part of Scotia it is, of course, the industrial capital—is more famed for its output of "strong waters"—in the way of whisky—than for its production, and consignment to their native element, of merchant ships; it can nevertheless boast of its achievements in the latter branch of industry as well. The Campbeltown Shipbuilding Co., entrenched as they are on French Point, within the land-locked bay or lock of Campbeltown, are exceptionally situated, so far as launching accommodation and steady plodding industry on the part of their employees are concerned, and this year already they have launched two steamers, and still have their fine building berths occupied. Three steamers are at present on the stocks—two of them near the plating stage of construction—and the keel of a fourth is about to be laid. This is on the berth vacated about a month ago through the launch of the screw steamer *Gorbea*, which is being engined by Messrs. Hutson & Sons, of Kelvinhaugh Engine Works, Glasgow, and will shortly run her speed trials on the Firth of Clyde. Though handicapped without doubt in various ways by reason of its isolation from industrial and shipping centres—the facilities for procuring and transport of material, for instance, as well as for the "dropping in" of owners' agents, consulting engineers, &c., being limited, to say the least—it is pleasing to note that the Campbeltown Shipbuilding Company is meeting with the success that is born of enterprise and satisfactory workmanship. The isolation referred to is not without its advantages, especially where sufficient enterprise and perspicacious gauging of the prospective needs of the shipping industry are to the front. These qualities seem to be "all there" at Campbeltown, and as a matter of fact, though most of the vessels the company produce are what are known as "spec" boats, seldom, if ever, are owners waiting when once the launching stage has been reached.

THE NEW YORK PUBLIC LIBRARY ASTOR, LENOX AND TILDEN FOUNDATIONS

The Marine Engineer.

LONDON, MAY 1, 1899.

MANY of the papers communicated to the Institution of Naval Architects necessarily are devoted to the consideration of stresses in a ship's structure, mainly interesting to those only who are engaged in the designing and building of ships' hulls. Such a paper is that contributed by Mr. J. Bruhn upon the stresses at the discontinuities in a ship's structure, which, however, is characterised by the attention given to the abnormal stresses set up in the plating about any discontinuities in the plating, such as hatchways and bridges. The author, after giving the usual and simple formulæ which serve to indicate the longitudinal and shearing stresses in a plain continuous hull, embodies these results in plain diagrams, showing, by the lightening and thickening of the stress lines, the general accumulation of the longitudinal and shearing stresses throughout the hull, assuming only one maximum bending moment. The results are interesting, graphically, to any reader, indicating the accumulation of the longitudinal strains in the upper and lower plating amidships, and the concentration of the shearing stresses in the central plating at distances about a quarter from either end of the vessel. A very distinct mental picture is also given of the general effect of all these superposed stresses under the various conditions of pitching or rolling by likening them to a network of stresses of which the meshes open and close as the moments vary. The exact calculation of the variable stresses produced about discontinuities, such as hatchways and bridges, presenting formidable difficulties, the author explains some very interesting experiments with sheet rubber of about ⅛ in. in thickness, cut so as to represent the discontinuity of hatchways and bridges, and strained to show by the elastic distortion of the surface the magnitude of the stresses about such discontinuities. The surface of the sheets were all lined out when in normal condition with fine parallel lines ¼ in. apart, both parallel to, and perpendicular to the direction of the pull, forming a complete set of squares, which, when the material was strained, became parallelograms. The elongation of these figures represented the strains, and the shearing strains by the alteration in the angles of the parallelograms. The results, when accurately measured, gave diagrams of the relative strains about such hatchways and the ends of bridges, naturally leading to direct information as to the character of the best doublings for a hatch corner, and for the best distribution of the thicker plating at the sides of the hatchways carried through continuously, and thinner plating between hatches, unless this distance was four times the width of the hatchways. In bridge stresses also important deductions are made, such as that the stresses increase with the length of the bridge, and larger in shorter than in longer wells, or higher in the way of narrow doors than in the way of broader ones. When a large amount of the material of the top sides is placed on the bridge, the shearing stresses at the end landings will be proportionately increased. The landings should be treble riveted, or a doubling plate should be joggled over the edge of the plate below to bring the rivets in double shear. As all structures are as weak as the weakest part, it is most important for ship architects to know from such information as this where the points of greatest stress lie, and how such extreme stresses should be dealt with.

OF a still more restricted scope were the notes communicated by Mr. C. F. Munday, serving to point out from the practical experience gained in the Royal Naval College, Greenwich, that a method of performing ship calculations to obtain cross curves of stability on a quadrature rule by M. Tchebycheff, and communicated in former transactions of the Institution by M. Kriloff, has proved to be much shorter than Simpson's method, and even more exact. The Russian method appears to be of great simplicity for the calculation of mid-ship and other cross-section areas, and also for water-line areas, thus giving displacement; but it is in using the rule with the integrator for cross curves of stability that the saving in time, and the reduction or avoidance of error by the simplicity of the calculations, are mostmarked to the advantage of the Russian method. It is at least strange to find that the Russians can teach something to British naval architects, but it is equally to the credit of the latter that they so readily admit this and profit by the suggestion.

MR. CHARLES H. HASWELL, from his vast range of experience, concludes some former reminiscences of the construction and operation of early steam-engines and steam navigation in the United States by a schedule of further interesting facts and steps in inventions and improvements introduced in the United States between 1807 and 1850. We cannot attempt to reproduce all the interesting steps of development indicated; but we may note that it was not until 1827 that any dry dock or marine railway existed in the United States in which, or on which, the bottom of boats could be cleaned of barnacles, breamed or metalled. When such operation was necessary, the hold was discharged, and large blocks and falls were led from her tops to a pier or bulkhead at low water and set taut. Then, as the tide rose, her outer side and bottom would be exposed and could be treated.

In 1842 Edwin A. Stevens, of Hoboken, designed and operated a closed fire-room in the steamboat *Rainbow*, supplied with air by a fan-blower located externally, and in 1845 the system was introduced in the United States steamer *Mississippi*. In the same year Captain John Ericsson applied screw-propeller blades to the sides of a steamboat like to a side wheel with diagonal blades, but they were not satisfactory. In 1844 Henry R. Worthington, of New York, designed and patented an independent steam fire and bilge pump, and in 1859 a duplex valve motor. In 1848 Frederick E. Stickles designed what is said to be the first application of a steam-engine to the rudder of a vessel, and successfully introduced it in operation.

WE are pleased to see that Mr. James Howden, so well known in connection with his forced draught system, still maintains his convictions that nothing can beat the Scotch or cylindrical boilers with a forced draught for marine purposes, and has the courage to express his convictions to the Institution of Naval Architects, in spite of the pseudo-fashionable craze for the water-tube boilers, and in spite of the fact that this author's ideas have not always been received with the attention that after experience has proved they merited. A good, healthy, and good-tempered opposition in engineering, as in politics, is always to be encouraged, and the old cylindrical boilers have been too long faithful and reliable servants to be discarded lightly, and without serious consideration. Mr. Howden, in dealing with torpedo-boat destroyers for sea service, of which so many are now being constructed, points out very reasonably that the destroyer, to be of protective service to an accompanying fleet, must be a sea-going vessel capable of keeping the sea in all weathers; or else an attacking fleet, when approaching a hostile port or coast, may be without the protection of the destroyers against the insidious attack of torpedo boats from the hostile port or coast. In support of these views Mr. Howden, quotes Mr. Dickie, an American engineer of great experience in naval construction, who has before him the tangible results obtained in the recent naval contests between the United States and Spain. Mr. Dickie is emphatic that the torpedo-boat destroyer, as at present constructed, does not come near meeting the requirements of sea-going service. Mr. Dickie therefore advocates torpedo-boat destroyers of 250 ft. length on the water-line, and 640 tons displacement, with a trial speed of 25 knots, which he reduces to 15 knots for Pacific sea voyage, or 20 knots for a coast voyage on the Pacific. This vessel would have a radius of action at 12 knots of 3,200 knots, and could keep the sea in all weathers. Mr. Howden, agreeing with the arguments of this gentleman as to the advantages to a fleet of such a sea-going torpedo-boat destroyer, goes one better, and asks whether a maximum sea-speed as 23½ knots is not sufficient for all practical purposes; and, if so, what is the use of hampering and vitiating the design by insisting upon such abnormal speeds as 25 or 30 knots an hour if the consequence is to prevent their utility as sea-going boats. With this slight reduction of maximum speed, which, however, is to be available at all times at sea, Mr. Howden gets in the claim for the cylindrical boilers and forced draught to be considered, with their well-known reliability and trustworthiness against sudden failure, and availability in all weathers with a small stoking staff, and with their well-known power for constant endurance at their maximum evaporation. With a 640 tons displacement, he shows that cylindrical boilers and forced draught for the suggested maximum sea speed of 23½ knots can be got in, and recommends the result as well worth the attention of the Admiralty.

THE horse-power absorbed by skin friction and wave making still appears to be wrapped in somewhat of a fog. Mr. James Hamilton has communicated some of his doubts and dilemmas on the subject to the Institution of Naval Architects, in his paper on the communications forwarded by Messrs. Inglis and Denny, and Professor Biles, on the subject of Mr. James Hamilton's paper on the horse-power absorbed by skin friction and wave making. Apparently specific examples do not appear to concur with Dr. Inglis's curve, as for instance the *Livadia* mentioned by Mr. Hamilton. As to Professor Biles's diagrams, Mr. Hamilton confesses he can make nothing of them, if they are what they profess to be. Mr. Denny has applied Mr. Hamilton's formulæ to six specific examples, with the result that the constant of

$$\frac{S^3\ D^{\frac{2}{3}}}{\text{I.H.P.}}$$

varies considerably in the various cases, and that without obvious reason, and even paradoxically. As an explanation, Mr. Hamilton points out that in all methods the efficiency of the propeller is assumed to be constant, and this is mixed up with skin friction, wave making, and engine friction. The conclusion arrived at by Mr. Hamilton is that, before such matters can be fairly analysed, the horse-power must be split up into its various parts, if only to discover the propeller efficiency in each case, and the engine friction.

Marine Engineers' Examination.—At the examination held on April 11th, 12th, and 13th, the following candidates passed for Extra First-class Engineers: Mr. A. Scott, of Liverpool, and Mr. T. Robertson, of Glasgow; the latter passing the first time of going up, and being prepared entirely by corresponpence. They were prepared by Mr. W. H. Thorn, 5, Waterville Terrace, North Shields, making 59 pupils who have passed in the above grade from this establishment, a number far exceeding that from any other existing school.

ORPEDO-BOAT BUILDING ON THE THAMES.

nuch to be deplored from a national point of view that Admiralty have not seen their way to place any of the new destroyers with one or more of the shipbuilding the Thames, since any slackness of work in these yards the loss of specially trained workmen, which loss cannot e good should a sudden demand for increased output necessary. The importance of this careful training ne home to the writer by watching the behaviour of a e torpedo-boat destroyer on which he had the pleasure ing a trial trip. Everything went "like clockwork,"

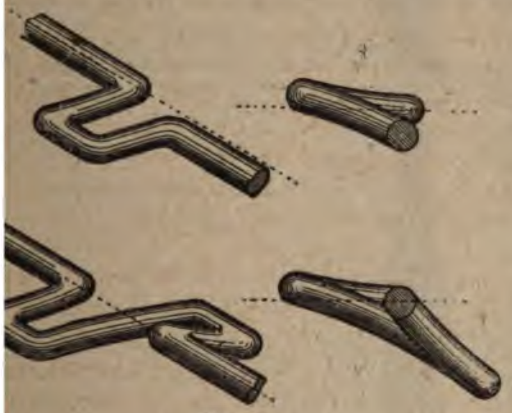

Fig. 1a.

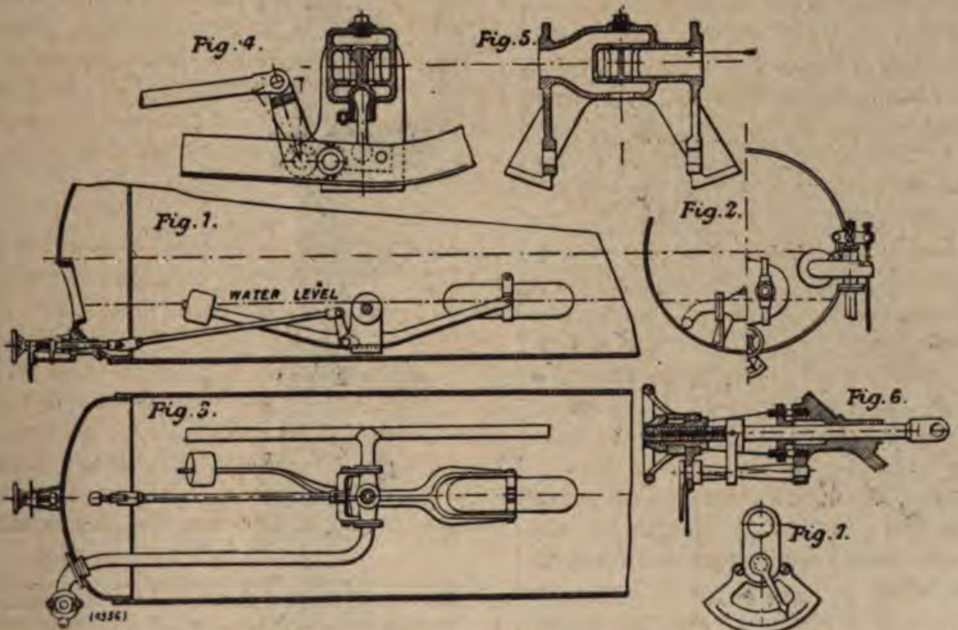
s familiar phrase well expresses the excellence of the nship necessary to achieve such a result, and the necessity maintaining at their full efficiency the staff of such her builders, Messrs. John I. Thornycroft & Co., by their output at a steady and fairly high rate.

firm consists of two partners, one of whom, Mr. John on, who is, we regret to hear, seriously ill, has done good both in a public capacity as Chief of the Ordnance ent, at Dum Dum, in India, and in other appointefore, as well as in a private capacity since he became a in this now well-known firm. The other, Mr. John I. roft, is well known as a pioneer in the shipbuilding



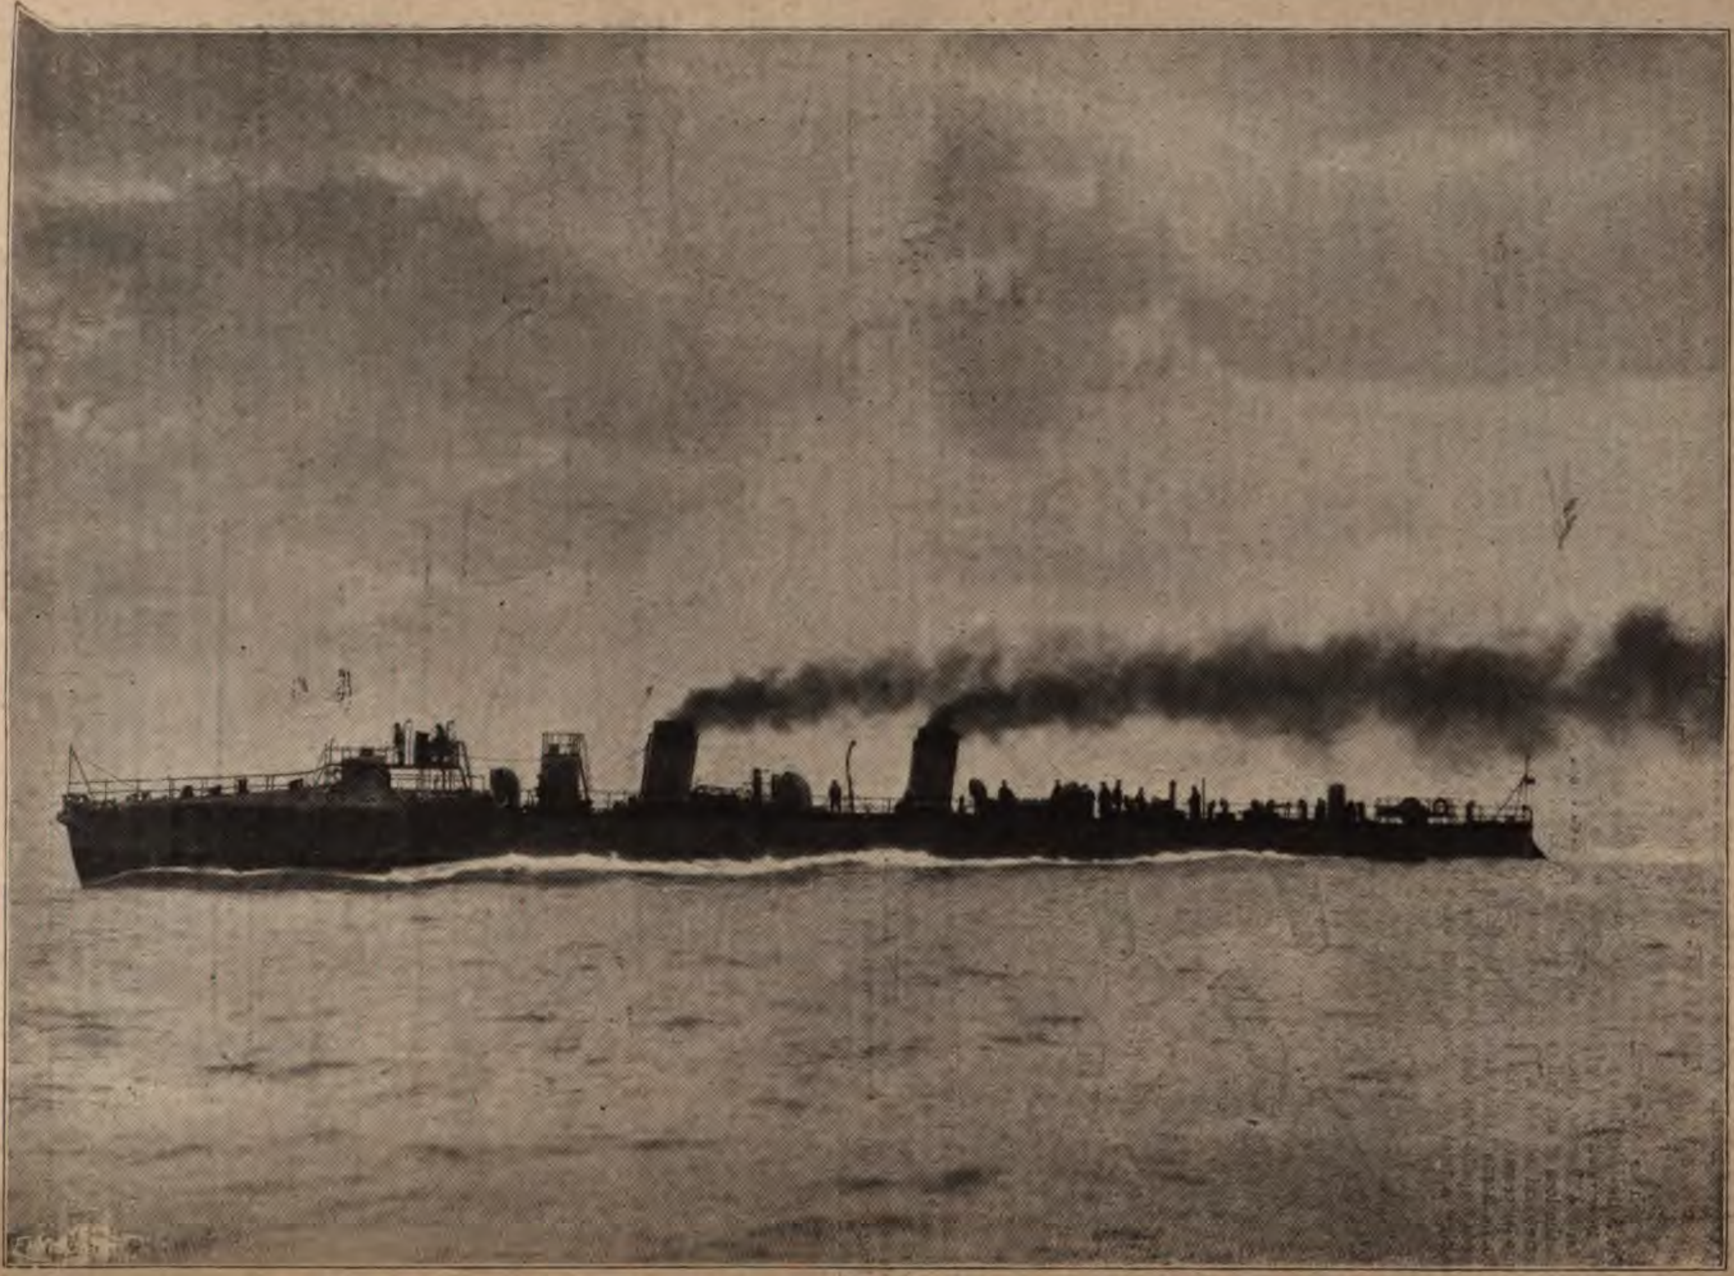
world. The late Chief Constructor of Her Majesty's Navy, Sir Nathaniel Barnaby, said in a recent lecture: "Out of the four great steps in speed-making which will make the last quarter of a century illustrious Mr. Thornycroft must be credited with three. Mr. Thornycroft in his several successes had given us a new form of boat, a new system of construction, a new form of propeller, and an effective way of generating steam by methods which had often been tried unsuccessfully and abandoned."

Mr. Thornycroft is a distinguished man of science and is one of the few engineers in England who have been awarded the Fellowship of the Royal Society, and the volumes of the Transactions of the Institution of Naval Architects and of the institution of Civil Engineers demonstrate that this honour has been well deserved. Both partners were distinguished pupils of the late Professor Rankine.

The small tube type of water-tube boiler, referred to by Sir N. Barnaby, did not find much favour with manufacturers and others until its merits were proved by the performance of the *Speedy*, which was fitted by Messrs. John I. Thornycroft & Co. with their patent boiler, with a result that this vessel developed 1,000 H.P. more than her sisters, which were fitted with locomotive boilers. Since then the small tube "express" boiler has rendered possible the 30 and 32 knot destroyers which are to-day being constructed throughout the world—mostly with boilers of Thornycroft type.

It was in 1885 that the Admiralty decided to build a number of vessels of the same size and speed as the torpedo boat, but with superior gun armament. Torpedo boats carried Nordenfeldt or Hotchkiss guns, firing steel shot between ½ lb. and 1 lb. in weight. The new catchers were to fire 3-pounder quick-firing shell guns and three two-barrelled Nordenfeldt guns. They were 125 ft. long, of 65 tons displacement, and with a guaranteed speed of 19 knots per hour. The speed was exceeded on trial by from 1 to 2 knots They were finally fitted out as torpedo boats.

In 1886 a new class of catcher of the *Rattlesnake* class was built. This boat was 200 ft. long, 23 ft. wide, of 550 tons displacement, engines 2,700 I.H.P., and speed 19 knots. The armament was a 4-in. gun and 6 three-pounder quick-firing guns, besides torpedo tubes. Then followed the *Sharpshooter* class—length, 230 ft.; beam, 27 ft.; and draught, 8 ft. 3 in.; engine, 4,500 I.H.P.; and speed, 21 knots. Locomotive boilers were fitted in them, and only 3,700 I.H.P. could be obtained, and a speed of 20 knots per hour. In 1892 eleven of the same class were built, with a displacement of 810 tons. They had locomotive boilers, developed 3,700 I.H.P., and attained a speed of 19½ knots. One of the eleven was the *Speedy*, and the builders, prevailing on the Admiralty to allow them to fit in their water-tube



THE JAPANESE TORPEDO-BOAT DESTROYER "MURAKUMO," BUILT BY MESSRS. J. I. THORNYCROFT & Co., CHISWICK, LONDON.

boilers, attained with them an increase of 1,000 I.H.P., and a speed of 20½ knots on trial.

Then came the *Daring* type of torpedo-boat destroyer, the speed of which was to be 27 knots. The *Daring* was 185 ft. long, 19 ft. beam, and draught 7 ft. The *Daring* attained a speed of 27·706 knots on trial, and the *Boxer*, of the same class, 29·175 knots. The last trial of the *Albatross* (on the 7th ult.) showed 32·294 knots per hour. We give a full page illustration of the Japanese torpedo-boat destroyer *Murakumo* (darkening clouds).

These high speeds require the greatest care to be taken in the balancing arrangements. The cylinders are inverted, and lie at an angle of about 12 deg., to the vertical. This admits of the cranks being brought close together without an intervening bearing; an arrangement which reduces to a minimum the disturbing couples which form so troublesome a feature in balancing problems. Two balance weights of moderate size only are found necessary, and certainly on the boat, even when going at 32 knots, the vibration is very slight indeed. The adjacent cranks are nearly opposite each other, and a model formed of a wire bent into the form of a crank, shown in the perspective view in Fig. 1a, shows a curious action when the wire is being twisted by means of a wooden disc at the end. When this is done there is only the twist transmitted to the wire at the other side of the cranks. With an ordinary crankshaft this is not so. The twist has in addition a lifting effect on the wire at a place where a bearing would be, and this would be followed by much friction. By arranging the cranks in the double form the friction, at an intermediate bearing, is obviated, and at the same time the pressure on the other bearings is greatly reduced.

On all trial trips water-service is provided for the wearing parts of the engines. The number of revolutions of the engines of the Japanese torpedo-boat destroyer being about 400 at full speed and the H.P. about 6,000, it can be understood that the effect of even a momentary increase of friction will be considerable. So water is used when necessary, and oil is supplied in plenty. The engine-room does not therefore appear to be the most pleasant place, or the craft of the engine-room artificer the happiest, in the world. It is in the closed stokeholds where things are entirely comfortable. The stokers seemed to be having an easy time of it, and almost doing their work sitting on their shovels. Certainly the atmosphere of the closed stokehold is not heated, the fan which produces the forced draught prevents that. One Japanese gentleman was sitting smoking cigarettes just in front of the furnace door in the most comfortable attitude possible. When the indiarubber-lined door of the stokehold was shut on us and we descended the stairs, we thought that something dreadful had to be undergone which in the interests of experience one had to suffer. The dreadful stories of the stokehold were in one's mind. The real experience gained was something very different. We wondered what it would be like when the trip was not a trial. If the interests of stokers are only to be considered, then the sooner the mercantile marine are fitted with small-tube water-tube boilers the better.

But, it may be asked, what about long voyages? Could the boilers be relied on to stand a long voyage? There was a torpedo boat, named the *Childers*, which had to be sent to Australia, in the early part of 1884, and the Admiralty, like other people, had its doubts about sending it so far a voyage alone. So a gun-boat was sent to take care of it and take it in tow. A storm came on, and the torpedo boat did not manage well in tow, the tow-rope broke and she got adrift. Those aboard the torpedo boat got up steam and went off to Australia and waited there for the gun-boat to come over. With the Japanese destroyers a speed of 200 revolutions and 20 knots is the easiest thing in the world to keep up as long as the coal lasts.

There is at the present time in the yard of Messrs. Thornycroft the racing yacht which will represent what England can do in the building of such craft. Considerable excitement has been occasioned by the attempts of outsiders to learn her construction and lines. These attempts have been unsuccessful. This vessel, the *Shamrock*, is to compete in the international yacht race between England and the United States, and if sound workmanship may do anything she will be sure to give a good account of herself. She has been designed by Mr. Fife.

Messrs. Thornycroft have very extensive shops at Chiswick, the number of men employed sometimes being as many as 2,000. The foremen and leading hands have been specially trained to their work, and some of them are known throughout the country as specialists. Mr. Milton, for example, informed the Institute of Naval Architects about the best manufacture of copper steam-pipes. The foreman coppersmith at the Chiswick yard knew everything about it long before, and was able to point out where Mr. Milton had not been correctly informed. There is a testing-room at Chiswick—a very essential part of the equipment of an engineering firm. The testing machine works up to 50 tons. The machine shop is very full, and a great number of the American quick-working tools have been introduced. There is a good forge with steam hammers for the small work, but the large forgings and iron or steel castings require to be made outside.

The Thornycroft water-tube boiler has been so much before the public of late in connection with the patent renewal case unfortunately unsuccessfully contested, and in connection with the record-breaking speeds of the destroyers, that it is almost superfluous to refer to it here. But, having seen the feed-regulator at work, and having seen it keep the level of the water absolutely constant, one is tempted to write a word about it. The figures representing this regulator are shown. Fig. 1 shows its elevation, Fig. 3 its plan. The principle is that of the ordinary ball-cock. There is the solid drawn-steel float held in the forked end of a lever. The float rises and falls with the water. The valve is shown in cross section Fig. 4, and longitudinal section Fig. 5. To regulate the quantity of water to suit the amount of steam being used, the vertical position of the fulcrum of the lever is altered. A hand wheel on the outside of the steam drum actuates the rod which regulates the amount of opening of the valve. Fig. 6 shows the piston, and Fig. 7 the front view of the indicator.

To hear some of those people with prejudices against small-tube water-tube boilers, one would get the impression that a tube was breaking down every few minutes, and that the fires were being raked out to allow of its renewal as often. There is a good story of one of the early boilers sent to work a mission launch on the Congo. It was sent out in pieces, and the man sent out to fit it up unfortunately fell a victim to the climate and died. The missionary, being an intelligent gentleman, got a little help from niggers, and built it in the boat, and it worked splendidly. Later, an engineer came out to the Congo with more prejudices than the missionary and the niggers. He condemned the boiler, took it out of the boat, and put in a vertical one in its place. The Thornycroft boiler was fitted up at a saw-mill, and when, after a year or so, the vertical boiler failed, the engineer anxiously applied to get the water-tube boiler back again, but the owner of the saw-mill would not part with it. Another Thornycroft boiler was therefore supplied.

TRIALS AND EXPERIMENTS MADE IN H.M.S. "ARGONAUT."*

By Sir John Durston, K.C.B., R.N., Engineer-in-Chief of H.M. Navy, Vice-President.

THE following paper gives an account of the results of the contract trials of H.M.S. *Argonaut* and certain experiments made while these were being carried out. Advantage was taken of the opportunity of making measurements of the actual water consumption of the engines under various conditions, with special measuring tanks fitted for this purpose.

The *Argonaut* is a twin-screw cruiser of 18,000 I.H.P.

The experiments were carried out on the specified contractors' trials, viz.: the thirty hours' trial at 3,600 I.H.P., a trial of the same duration at 13,500 I.H.P., and the full-power trial of eight hours at 18,000 I.H.P.

The engines are of the same dimensions and arrangement as those of the *Diadem*, described and illustrated in the paper read last year and given in our May, 1898, issue. They consist of two sets of triple-expansion engines arranged in separate engine-rooms divided by a middle line bulkhead, and are designed to develop the full specified power with an initial pressure at the engines of 250 lbs. by gauge. The boiler pressure is 300 lbs.

The diameters of the high, intermediate, and each of the two low-pressure cylinders are 34 in. 55½ in., and 64 in. respectively. The stroke is 4 ft., and the designed revolutions are 120 per minute, or ten more than the designed speed of revolution of the *Diadem*.

Each cylinder has a separate working barrel, which forms a steam-jacket with the cylinder walls. Steam may be admitted to these jackets and maintained at any desired pressure. The condensed jacket steam is led to collectors furnished with gauge

---

glasses and drained into the main condensers by screw-down valves.

The cylinders are arranged high and intermediate forward, and the two low pressures aft. The two forward cranks being opposite one another, the two after cranks are also opposite one another, but at right angles to the two forward cranks. On all the trials there was an entire absence of vibration of the ship.

The high and intermediate cylinders are fitted with piston, and the low pressures with double-ported flat slide valves; these are actuated by the ordinary link motion. The reversing gear is of the "all round" type usual in naval engines, and provision is made for adjusting the position of each link independently.

There are a feed and a hot-well tank in each engine-room wing, these are fitted with connecting pipes to the corresponding tanks on the other side of the ship.

Steam is supplied by thirty Belleville boilers of the economiser type. They are arranged in four groups, back to back, and are stoked in the fore and aft direction. Transverse bulkheads divide the boiler space into four separate compartments.

The total heating surface provided is 47,300 sq. ft., consisting of 28,300 sq. ft. in the generator portion and 19,000 sq. ft. in the economiser portion, as against a total of 40,550 sq. ft. in the *Diadem*, viz., 29,600 sq. ft. in generator and 10,950 sq. ft. in the economiser portions respectively. It will be noted the proportion of economiser to generator heating surface is much larger than in the *Diadem*, but the proportion in the latter was due to her boilers having been altered to economiser type while in course of construction. The exact proportion, however, is not definitely settled, and so far as experiments have gone at present, the ratio of these two surfaces may vary considerably without affecting economy, as long as practically the same total heating surface is maintained. The grate area is 1,390 sq. ft.

There are two main condensers with a total cooling surface of 19,000 sq. ft. Each is provided with circulating water by two independent centrifugal pumps, 45 in. in diameter, placed in its own engine-room. Bilge suctions are fitted to these four circulating pumps, and each is capable of discharging 1,200 tons of water per hour from the bilge. There is in each engine-room a hot-well pump for taking water which has been delivered by the main or auxiliary air pumps to the hot-well tank, and discharging it through a filter to the feed tank; an evaporating and distilling plant, the two being capable of making 90 tons of water per day when worked non-compound, and 56 tons when worked compound, for the boilers, or 32 tons per day for drinking purposes, and the usual auxiliary condenser for condensing the exhaust steam from the auxiliary engines; this condenser furnishes a cooling surface of 1,100 sq. ft., and has its own circulating and air pumps.

Besides these, a steering, a ventilating, an electric light, and two fire and bilge engines are placed in each engine-room; a third electric light engine being situated in another compartment.

Each of the stokeholds has its furnace air-pumping and ventilating fan; and each boiler-room a main and an auxiliary feed engine.

Outside the machinery space there are engines for air-compressing, boat, coal, and ash hoisting, capstan working, refrigerating, &c.

The *Argonaut's* trials took place in the English Channel, the trial at 13,500 I.H.P. taking place on November 29th and 30th, 1898, that at full power on December 3rd, and at 3,600 I.H.P. on the 12th of that month. The displacement of the vessel on all the trials was about 11,070 tons, and speeds of 21·14, 19·94, and 13·16 were observed over a measured course of 23 knots for the full, continuous steaming, and 3,600 I.H.P. trial respectively.

A table is appended showing the average weights of machinery and heating surfaces of the boilers of the ships of the *Diadem* class, and of two ships of the *Argonaut* class, which have made their steam trials.

In comparing the figures, it will be seen that there is a decrease of grate surface in the *Argonaut*. This is due to the fact that the proportion of heating surface was increased in the economiser; the corresponding reduction of generator surface (the number of stages in the element remaining the same) leading to a decreased number of elements, and consequently of firegrate in proportion to the power.

As to the efficiency of these arrangements, it will be seen that the consumptions of coal in the case of the *Argonaut* class are slightly smaller than in the *Diadem* class; while, due to the substitution of economiser for generator heating surface, and to the increase of the number of revolutions in the engines, there is a decrease in weight per I.H.P. of about 9 per cent.

The water-measuring appliances were arranged primarily to ascertain the quantity of steam used for the main engines under various conditions as regards jacketing of cylinders, steam pressure, and rates of expansion. Opportunity was also taken to make certain observations as to the amount of steam used by the auxiliary engines; but this was not the principal object in view, and the various alterations of pipes necessary to enable an accurate separation to be made between the steam used by the auxiliary engines necessary for the propelling engines and the other auxiliary engines of the ship were not made.

The arrangements adopted may be briefly described as follows:—First, in order to measure the total water passing through the main and auxiliary condensers, the hot-well pump discharges were disconnected from the grease extractors and connected in each case to a pair of measuring tanks placed on the upper deck, as shown in the diagram. These were alternately filled and emptied, the water, when measured, flowing by gravity through the grease extractors into the feed tanks. Each of the four tanks was of 240 cub. ft. capacity, which gave about five-minute intervals between the times of switching from one tank to another when running at full power. It was arranged that the only steam or water entering the main condenser, except that from the separator, which was measured and allowed for, was that from the main engines and their jacket drains, so that the economy or otherwise of the various methods of working the main engines could be exactly ascertained.

To measure the water passing through the auxiliary condenser, the auxiliary air pump discharges were disconnected from

the grease extractors and arranged to discharge to small measuring tanks of about 30 cub. ft. capacity. As in the case of the large tanks, these were fitted in pairs; they were placed on the upper engine-room platform, and the water was run from them to the hot-well pump suctions, its quantity being thus included in the amount measured by the large tanks on the upper deck. The difference in the quantities of water measured by the small and the large tanks thus gave (subject to the allowance named above) the water used by the main engines and jackets. The diagram shows in principle the arrangement of tanks and connections employed, unnecessary detail being eliminated for the sake of clearness. Identical arrangements were made for measuring both the total and auxiliary water from each engine-room.

THE ABOVE SKETCH INDICATES THE GENERAL ARRANGEMENT, BUT FOR CLEARNESS, THE EXACT POSITIONS HAVE BEEN SLIGHTLY ALTERED.

The slide valve settings in full gear, as actually measured, give the following cut-offs in the respective cylinders:—High pressure 73 per cent.; intermediate pressure, 67 per cent.; and low pressure, about 46 per cent. of the stroke. The cut-offs used during the trials are given in the tables.

It should be observed here that, as arranged for convenience of comparison in the tables, the order is that of the total ratios of expansion. The alphabetical order of the reference letters *gives the actual sequence of the trials*. The general scope and *results of the tests made are shown in the tables*.

Referring to Table I., which deals with the 8 hours' full-power trial, the main linking gear was run out to "full gear," and the high-pressure independent gear was used as found necessary to maintain the required power. The steam pressure at the engines varied from 236 lbs. to 244 lbs., and that at the boilers from 290 lbs. to 299 lbs. The real ratio of expansion was 8·5 throughout the trial.

The trial was started with the jackets out of use. After three hours the low-pressure jackets were filled with steam of about 20 lbs. pressure above that in the receiver, and remained in use for the remainder of the trial.[*] For the last two hours, the other jackets were also brought into use, the pressure maintained in the intermediate being about 20 lbs. above that in the receiver: but that maintained in the high-pressure jacket was not so high as its receiver pressure, it being apprehended by the contractors that the cylinder walls might become too dry for efficient working at the high piston speed required for maximum power.

Turning to Table II., which deals with the trial at 13,500 I.H.P., or the maximum continuous steaming power, it will be observed that the conditions of initial pressure and ratio of expansion varied considerably throughout the trials. The thirty hours was divided into six periods of four and one-half hours each, and one of three hours' duration.

---

[*] In dealing with the tables and the following description it should be borne in mind that the engines are jacketed on the cylinder barrels only.

In trials G, C, D, the main and high-pressure independent linking gears were used to regulate the power. In trial G, with 12·5 expansions, all the jackets were in use, the pressure of the receiver being maintained in the high-pressure jackets, and pressures above those in their corresponding receivers in the intermediate and low-pressure jackets. In trial C, with 10·4 expansions, the intermediate and low-pressure jackets were used, the pressure maintained in them being in excess of their received pressure; while in trial D, with the same ratio of expansion, all the jackets were shut off. The steam pressure at the engines during these three trials varied from 229 to 248 lbs., and the boiler pressure from 251 to 280 lbs.

In trial F the main linking gear only was used to regulate the power obtained, the slide valves of all the cylinders being thus linked up. In this case 9·7 expansions were given, and the steam at engines and boilers was respectively 235 and 275 lbs. No jacketing was used on the cylinders.

In trial B, with 9·1 expansions, the main links were run out to full gear, the high-pressure independent link being used to obtain the cut-off; in this case steam of 287 lbs. was used at the boilers, and 190 lbs. at the engines, and, as before, no jacketing was used.

In trials A and E, again, the jackets were out of use, all the slide valves were in full gear, and the total expansion was 8·3

times. In trial A the steam pressure at boilers was 194 lbs., and in trial E 282 lbs., the pressures shown at the engines being about 170 and 180 lbs. respectively, the difference between these two trials being that in one case the boiler steam was of higher pressure and reduced more by throttling than in the other.

In Table III. it will be seen that the thirty hours' trial at 3,600 I.H.P. was divided into six equal periods, each of five hours' duration.

In trials A, B, and C, the main and high pressure independent linking gears were set to obtain the required power, the total expansion being 15·7 and the steam pressure at engines being about 168 lbs., and averaging 285 lbs. at the boilers. In trial A the high-pressure jacket carried nearly the same steam as the receiver; the intermediate and low-pressure jackets being maintained at about 20 lbs. above theirs. In trial B the high-pressure jacket was not in use, the steam pressure in the other jackets being maintained as in A. In trial C, as in the succeeding trials, D, E, F, the jacketing was entirely shut off.

In trial D the main links only were used to obtain an expansion of 13·2, the steam at the engines being 142 lbs., with a boiler pressure 280 lbs.

In trial E the main linking gear was in full gear, the high-pressure independent gear only being used to obtain the cut-off. 9·1 expansions were given to the steam; the pressure at the engines being about 78 lbs., and at boilers 285 lbs., this was reduced by throttling.

In trial F, all the links were placed in full gear, and with a total expansion of 8·3, 68 lbs. was the pressure used at engines.

and 130 lbs. at boilers to obtain the power. No lower boiler pressure than this being practicable on account of the working of the electric light and steering engines.

Now to examine the effect of jacketing, as shown in these trials.

It will be seen by referring to Table I. that the engines were, with the exception of the alteration in the use of the jackets, under the same conditions in trials C, B, and A; and that the steam consumption varied from 16·64 lbs. per I.H.P. per hour when all the jackets were in use to 15·75 when all were shut off, it being intermediate, or 16·15 lbs., when the low pressure jacket only was in use. Thus, the consumption due to main engines and jackets was reduced ·89 lbs. per I.H.P. per hour, or 5·3 per cent., in changing from condition C to condition A, and ·49 lb. per I.H.P. per hour, or 2·9 per cent., from C to B.

In table II. trials G, C, D were under similar general conditions, as in Table I., as regards the use of jacketing, except that the high pressure jacket only was shut off in trial C. Trials C and D were carried out at an expansion of 10·4; trial G, which was at the end of the 30 hours' contractors' trial, was made at 12·5 expansions. Hence, although G shows a slight advantage to the jackets, compared with C, yet to compare the results of this trial with those on Table I. we will take C and D only. Here also there is a reduction of water consumption with jackets out of use, of ·43 lb. per I.H.P. per hour, or 2·7 per cent. between C and D.

In Table III., trials A, B, and C are under the same general conditions of steam pressure and expansion, and only differ as regards the use of the jackets. Here again, although in a very slight degree, there is a reduction of water consumption when

Total I.H.P.		9,107

the jackets are shut off, viz., ·06 to ·08 lb. of water per I.H.P. per hour, or rather less than ½ per cent.

Bringing these results together, the trials show approximately an increase of water consumption per I.H.P. per hour through the use of jackets as applied therein of—

·9 lb., or 5·3 per cent., at 18,000 I.H.P.;
·4 lb., or 2·6 per cent., at 13,500 I.H.P.; and
·06 lb., or less than ½ per cent., at 3,600 I.H.P.

The points of difference in these trials, which would affect the relative efficiency of the use of steam jackets, are the revolutions and expansions, and it appears that with the comparatively low revolutions and high expansion used at 3,600 I.H.P., the influence of the jacketing on the efficiency of the steam practically balances the expenditure of heat in the jackets, and that at lower speeds and powers, such as obtain at the cruising speeds of a fleet, a gain would probably be shown by the use of the steam jacket. At the higher powers the tests appear to show that no gain in economy is obtained by steam jacketing as carried out in this vessel.

Next considering the effect of the links.

On the full-power series the setting was not altered, and, therefore, had no effect on the consumption.

In Table II. trials D, F, B, E, and A were carried out without the use of the steam jacket, and the results may be exhibited as follows:—

	D.	F.	B.	E.	A.
Expansions	10·4	9·7	9·1	8·3	8·3
Lbs. of Water per I.H.P. per hour	15·44	15·36	15·97	16·22	15·73

It will be noticed that trials A and E took place at the same ratio of expansion, the difference being in the boiler pressures maintained.

In table III. the expansions vary from 15·7 in trial C to 8·3 in trial F, no jackets being in use in any of these trials. The consumptions are shown in the following table:—

	C.	D.	E.	F.
Expansions	15·7	13·2	9·1	8·3
Lbs. of Water per I.H.P. per hour	16·26	16·68	17·58	17·72

And it will be seen that corresponding to a decrease in the expansion from 15·7 to 8·3 there is an increase of about 9 per cent. in the consumption.

The consumption of water for all auxiliary engines in use throughout the machinery department and the ship during the hours in which the evaporators were not in use was, relatively to the power of the main engines:—

3·57 lbs. per I.H.P., or about 22 per cent. of the consumption of main engines only on the trial at 3,600 I.H.P.

1·59 lb. per I.H.P., or about 10·4 per cent. of the consumption of main engines only on the trial at 13,500 I.H.P.

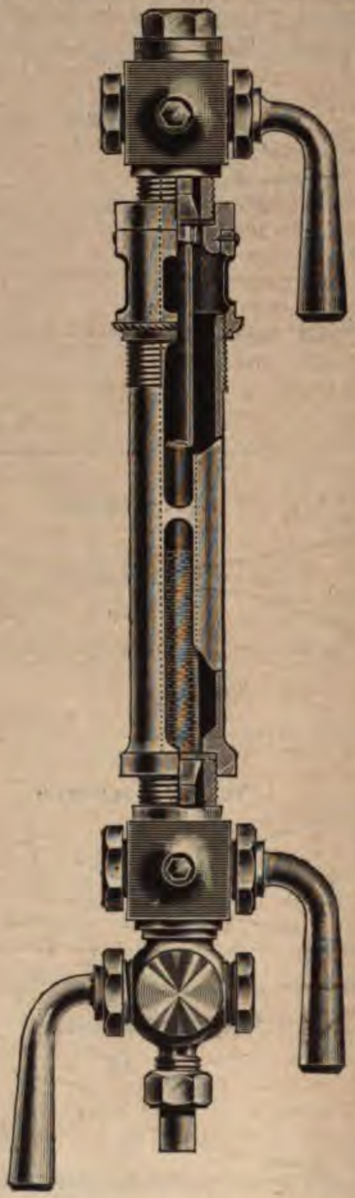
During the full-power trial the evaporators were in continuous use, and the amount of water passing through the auxiliary condenser was 44,651 lbs. per hour. As the evaporators were worked compound, and the secondary steam was led through a distiller, the drainage water from the second evaporator, as well as the boiler steam used in the first evaporator, was included in this quantity. The amount of water made by the distillers was measured by tanks. Allowance being made on the basis of the results of separate experiments made on evaporators and distillers, by the same maker, it is estimated that the consumption of steam for all auxiliary engines (excluding evaporators) was 1·88 lb. per I.H.P. per hour, or about 11·9 per cent. of the consumption of the main engines only. This increase in consumption for auxiliaries over that at 13,500 I.H.P. was, no doubt, due to the fact that, while the auxiliary engines which had been used on the 13,500 I.H.P. trial were generally working at higher speeds corresponding to the higher power of the main engines, double the number of furnace air-blowing engines were in use, working at a considerably higher speed, besides eight fan engines, running at 150 revolutions per minute, which were in use on this trial only.

Specimens of the indicator diagrams are given, those selected being for the trial showing the smallest water consumption of the main engines in each table.

Marine Engineers' Examination.—At the quarterly examination of Extra First-class Engineers, held in April, Liverpool has come to the front this time again, and Messrs. Walter E. Pride, David Gibson, and William Moffat were successful. The three candidates were students of Pritchard's Marine Engineering Academy, 8, Walton Road, Liverpool.

VILE'S PATENT WATER GAUGE.

THE breaking of water gauge glasses is of very frequent occurrence, and in these days of high pressure the consequences are often of such a nature as to clearly prove that the risks of injury from such cause are very great. The variation in length of the glass due to the expansion and contraction set up by the changes of temperature to which it is subject under working conditions, such as when, for instance, the glass is blown through for the purposes of cleaning it and ascertaining that the communication with the boiler at the top and bottom is intact and in proper working, is no doubt one of the most fertile causes of the fracture. For instance, if the packing or other jointing means at the top and bottom mountings hold the glass tube so tightly as to prevent it sliding therein when the glass expands, a compressive stress is set up, which tends to buckle or bend it, thus



readily producing fracture; or, on the other hand, when the temperature of the glass falls it contracts and sets up a tensile stress, which also increases the liability to fracture.

Many ingenious and elaborate devices have been devised in the past to overcome these difficulties, but we know of no device so simple as that which we now have the pleasure of placing before our readers, and which has obtained a very good name after nearly two years' use on a large number of steamers.

It may be said that it is essentially designed to effect the joint between the gauge glass and the mountings, so that, under no circumstances of variable internal pressure upon the mountings and glass, shall there be direct end or high lateral pressure upon the glass; and further that, by a metallic extension piece surrounding the gauge glass in direct metallic continuity with the mountings a high and more uniform temperature shall be maintained in the immediate vicinity of the external surface of the glass. Another important feature is that the invention is readily applicable to existent fittings.

By reference to the illustration it will be seen that the mountings are of the usual construction, the ordinary screw gland nuts having been removed from the screwed noses of the top and bottom fittings.

The glass is supported in each mounting by a cupped or hat washer of suitable elastic material, which will stand the high pressure steam such as "Woodite." The cylindrical part of the washer is brought to a knife edge, so that the steam pressure will itself make a sliding steam or water-tight joint upon the gauge glass. The flanged portion bears against the ends of the screwed noses.

The washers are maintained in place by the pressure set up by the slotted extension piece provided at the upper end with a short screwed portion engaging upon the same, so that the length of the extension piece can be increased and decreased by the screwing on or off of this short piece. When the steam-tight joint is made by pressure, having the tendency to thrust apart the fittings, it will be noticed that no strain whatever comes upon the gauge glass itself, but it is practically supported in a floating condition, totally uninfluenced by any alteration in alignment of the axes of the top and bottom mountings. The extension piece merely engages over the noses of the mountings loosely, so as to be guided thereby. When the internal pressure is relieved in the act of blowing down a gauge glass, it is obvious that there would be a tendency for the mountings, which have been kept apart by internal pressure, to close sharply together, and thus the risk would be run of fracturing the glass. In the device under notice this effect is entirely obviated, as the extension piece prevents any such action. The slots in the parts of the extension piece are provided to enable the gauge glass to be seen whatever the position of the extension piece.

There is another good feature worthy of note, viz., that it is found that the high pressure or temperature, or both combined, produce a change in the molecular structure of the glass, and it is often necessary to change the glass before it actually breaks. This particular method of mounting lends itself very readily to such an operation, which can be effected in a very few minutes without any difficulty or danger attached thereto.

We have had the opportunity of inspecting copies of a large number of testimonials relating to the invention as to results in actual use, and in every case the device receives the highest praise as to its efficiency and simplicity.

The inventor and manufacturer of this device is Mr. A. Vile, of 5, Denton Road, Cardiff, who is a chief engineer of many years' experience, and knows the difficulties that have existed hitherto, and therefore is, in a very good position to find an easy solution to the problem.

THE FLEETS OF THE MAIL LINES.

(*From our own Correspondent.*)

The "Angerton."

AMONGST the wrecks of the month of March was that of the Newcastle steamship *Angerton*, a vessel of some 2,600 tons, and of fifteen years of age. She was formerly of the Milburn Line. In 1885 she was in a somewhat serious casualty, stranding on the coast of Portugal and sustaining very severe damage. On that occasion she was, however, floated, the salvors getting the handsome contract of £200 certain, and if successful—as they were—a lump sum of six thousand pounds in respect of their work for the hull, and a further fifty per cent. in respect of the cargo. Her recent loss, however, was complete, her hull and cargo being disposed of for little over three hundred pounds. On her final trip she was bound from a South Wales port to Alexandria with a cargo of fuel, and stranded on the Egyptian coast about fifteen miles west of Alexandria. It should be noted that at the inquiry held at Alexandria a few days ago the conduct of her chief engineer, Mr. J. J. Chandlish, was commended, though other of her officers were less fortunate.

The "Tarifa."

Few of my readers are aware probably that the old Cunard *Tarifa*, whose departure to the yard of an Italian shipbreaker I chronicled some little time ago, held an Atlantic record. I only learnt the fact myself within the last few days. Yet a fact it is. And it is a record which is twenty-nine years old and still unbroken. It was not a speed record, of course. The poor old hooker was not built that way. It was barometric. On the 5th February, 1870, the *Tarifa* saw the barometer down to 27·3 in., a lower reading than any which had been recorded before or has been since that time, though the Nederland American liner *Spaarndam* saw it very fairly low at 27·57 in. in February of the present year. I have looked the voyage in question up in my notes, and I find that the *Tarifa* left Liverpool on the 1st February, 1870, and sailed from Queenstown at 4.15 p.m. the following day. She was bound for Boston, where she arrived at midnight on the 15th, having made the passage in thirteen days and a half, which was by no means a bad run for her, considering that the crack Cunarder *Java*, which sailed for New York three days ahead of her, was thirteen days on the passage whilst the Inman Steamer, *City of Baltimore*, two days behind her, was only just under thirteen days in crossing. This latter vessel then held the record for a day's steaming. The fact that the *Tarifa* did not make a particularly bad passage on this occasion is especially noticeable when it is remembered that eleven and twelve days seems to have been the old ship's usual time.

The S. Lawrence Trade.

Arrangements in view of the opening of the S. Lawrence have been made some little time now. The Allan Line has arranged to run the Shaw, Savill & Albion steamship *Tainiu* for the summer season in place of the lost *Castillian*. The *Tainiu* had a great name in her original trade, and held the record both ways on the long sea route. But she was too expensive in her running for the altered conditions of her original trade, and it is some time since she has been on the station. Under a very elaborate Spanish name she served the Spanish before the war in taking troops out to Cuba. She will doubtless prove comfortable enough for the Canadians, but her speed of but fourteen knots can hardly be considered excessive for the North

Atlantic in the present year of grace. The company has also taken over the old *Gallia*, formerly a Cunarder and recently running for the Beaver Line Associated Steamers.

Some little time ago I mentioned that Messrs. Elder, Dempster & Co. had bought the goodwill of the Beaver Line and the surviving "Lake" boats from the liquidators of the Canada Shipping Company. The Messrs. MacIver, who had been acting as agents for the Beaver Line since its reconstruction, contended that the right to the name was vested in them. They had certainly done what they could to infuse new vigour into the concern, having acquired the Cunard *Gallia*, which I have just referred to, and the New Zealand *Tongariro* to supplement the exertions of the older vessels. The position between the two firms has now resolved itself into this. There is the Beaver Line (Elder, Dempster & Co.), which is intending to maintain a service with fine and large new twin-screw cargo boats, and which made its inaugural sailing to the S. Lawrence with the steamship *Monterey* on the 27th April. There is also another and rival line managed by the Messrs. MacIver. It calls itself (as it has a perfect right to do) the "Beaver Line Associated Steamers, Limited. It can do this for the reason that when Messrs. MacIver took the management of the Lake boats and acquired the *Gallia*, they formed a separate limited company under that style to purchase supplementary vessels. Thus, though the main name has been taken away from them, the subsidiary title remains. There are thus two lines in the place of one, and it would appear that the struggle between them will be keen enough; for Messrs. MacIver are reinforcing their fleet with another New Zealand boat. This is the *Ruapeha*, larger and more modern than the *Tongariro*. The *Ruapehu's* latest claim to distinction was her feat in towing out the great floating dock, built for the Spanish Government by Messrs. C. S. Swan & Hunter, of Newcastle, from the Tyne to Havannah.

Meanwhile, as I have already remarked here, the Dominion Line, whilst maintaining its hold on the S. Lawrence, is making a serious and successful attack on the British passenger trade, of which by this time it has acquried a practical monopoly.

The "Stella."

The awful disaster to a London & South-Western Railway steamer bound to the Channel Islands, with a holiday crowd, cast a gloom over the Easter of 1899, though, at the same time, there was a melancholy satisfaction in the account of the behaviour of the crew of the vessel, who miminised by their coolness and discipline the loss of life, and in that of the passengers who retained their presence of mind and their self-control under circumstances of peril to which they must have been total strangers. It would have been well if the cheap and nasty Press, the experts—so self-styled—and advertising members of Parliament could have shown something of the same quality of self-effacement and have evinced a little respect for the characters of those who were no longer able to reply in their defence, and shown some sympathy for the surviving relatives of men who died at their posts. Some of the comments which have been made upon mere hearsay evidence have been little short of scandalous. It will be quite time to speak of the disaster, and its causes and lessons, when the result of the enquiry ordered by the Board of Trade is made known.

I may, however, say something of the vessel herself. She was the last launched of the three sisters which, in 1890, the railway company had launched from the Clydebank yard of Messrs. J. & G. Thomson as a reply to the new Channel fleet of the Great Western Railway. They were fitted with twin screws and triple-expansion engines, the most carefully designed accommodation that long experience could suggest, a high rate of speed, sufficient size to make them comfortable sea boats—they were nearly 1,100 tons gross register—and soon made themselves popular. Appliances for safety were not forgotten, the vessels being divided into eight water-tight compartments. I notice that the *Stella* was unlucky at her launch, which was attempted on the 15th September, 1890. When nearing the water she unexpectedly stopped and the efforts of those in charge of the arrangements failed to move her. She was, however, safely floated on the following tide and sustained no injury by the occurrence. I only mention it because some of those who are connected with the sea still have their superstitions about the luck of launches, and they may be interested to note such facts.

The "Gaspesia."

On the night of the 16th April the unlucky *Gaspesia* arrived at last at the port of Trepassey, Newfoundland, being assisted thither by the steamer *Kite*. It appears, according to the reports which have been flying about, that an offer to salve the old P.S.N. boat had previously been refused by her master. One can hardly wonder at it if the terms of the would-be salvor were correctly quoted. He "only" asked the sum of 100,000 dols. This would be a good deal more than the vessel herself would be worth in her sound condition. For it is the exact sum at which Messrs. C. W. Kellock & Co. placed the sound value of the Cunard steamship *Pavonia* in the recent salvage suit. The *Pavonia* is nine years younger and 1,700 tons greater than this vessel. Still, the little *Kite*—she is a wooden screw sealer of but 280 tons gross, belonging to Messrs. C. T. Bowring & Company—has done very well for herself, her owners, and crew, even though she has performed the task without any agreement.

The damage to the *Gaspesia* seems heavy. Her rudder was reported as fractured very early in her term of imprisonment, and since she has got into port, it has been stated that she has both frames and beams broken by the pressure of the ice. So she must go into graving dock on the other side, and it will be some time before Milford sees her again.

The *Werra* and *Fulda* are still reported as lying in the docks at Birkenhead, and no announcement, up to the time of writing, has appeared as to the resumption of the ice-free service from Milford.

Speaking of

Messrs. Kellock's,

I may mention that this firm has now opened a London office at 59, Cornhill, E.C., in addition to its well-known offices in Liverpool, where it has been established for upwards of three-quarters of a century.

A Result of the Recent Heavy Losses in Missing Steamers

is seen in the recent order by the Committee of Lloyd's to the effect that any broker found dealing with a clerk (on private account) will be expelled from the institution. The rule is one which has long been in force on the Stock Exchange with salutary effect. Probably it has not been found necessary to adopt it at Lloyd's hitherto. It is practically only in the overdue market that outsiders can gamble. Speculation in this department seems heartless and indecent, for it is making bets on matters which closely touch the lives of hard-working men and the happiness of helpless women and children. Yet it is obvious that it would be neither possible nor just to forbid altogether insurance of this kind of risk. Many persons have very large and legitimate pecuniary interests, which they need to at least partly cover when a vessel is at sea for an unusual period without being reported and it would not be right to forbid their doing so. But anything which tends to check gambling pure and simple in this department is, in the cause of decency, to be very much welcomed.

A Change of Name.

The old Guion liner *Arizona*, once the holder of the "blue ribbon of the Atlantic," went out to work in the new Trans-Pacific service of the Northern Pacific Railroad Company—as may be within the recollection of my readers—after being re-engined and boilered by her builders, the Fairfield Company. The United States Government having acquired her as a trooper, she is now called *Hancock*, in memory of one of the generals of the United States army in the War of Secession.

The Cunard Company's Meeting

was held last month. I do not propose now to go into their accounts or to review their position. That is inviting enough for a candid critic, but it cannot be dealt with here. But at the meeting Lord Inverclyde, the chairman, took occasion to inform his shareholders that the retaining fee in respect of the steamers *Lucania* and *Campania* would—according to notice received from the Admiralty—be withdrawn in September. This was a very disquieting piece of news indeed, as it fell from his lips. We see how the Germans and the French are building vessels suitable for commerce-destroying in time of war, or for fast transport service when the exigencies of the times may require it. We have nothing but the *Oceanic* of this class, even under contemplation. The vessels of the American Line have just proved under the actual test of service conditions how invaluable this class of vessel really is as an auxiliary to naval operations. Any real discouragement to patriotic shipowners would have been most disastrous to the country. But the naval estimates show that no reduction in the amount to be expended in these retaining fees is contemplated, and the matter was at best the discovery of a mare's nest on the part of his lordship.

The fact is that the Admiralty have merely given the notice, to which Lord Inverclyde alluded, with a view to a possible revision of terms, and with the object of getting, if possible, a better return to the country for the money it annually expends in this direction. No one can find anything but approval for such a course of action.

The French Atlantic Trade.

The Compagnie Générale Transatlantique is making further extensions of its service. A new cargo line from Havre to New York, with a call at Paulliac, is under contemplation. The pigeon post too—for what it may be worth—is being pressed forward, and experiments in this direction are made with every west-bound steamer of the mail line. In order to encourage the emigrant traffic from Italy, special trains, originating at Modane, on the Italian frontier, are run in connection with every mail steamer from Havre. But serious opposition is threatened to the company. The vessels of the American Line—commencing with the westward trip of the steamer *New York* in April—now call at Cherbourg on both the eastward and westward trips. The Hamburg American Line calls at Cherbourg with its express steamers, and is also starting a new intermediate service with big twin-screw passenger and cargo boats from Hamburg and the Thames, calling at Boulogne-sur-Mer, whilst the Nord-Deutscher Lloyd continues to put in at Cherbourg with its express steamers on its way to and from Southampton.

The West Indian and Pacific Steamship Company

continues its good luck (or good management) of 1898. One of its 8,000-ton twin-screw boats, the *American*, has been chartered to the National Line to help the new steamer *Manhattan*, of the same size, to maintain the London and New York service. The sister-ship *European* has just towed the broken-down steamer *Silverdale*, of Newcastle (owned by Messrs. Milburn), into Bermuda, and will, no doubt, thereby make a good salvage, as the *Silverdale* had broken her shaft and was entirely disabled when the *European* came along. The new boats of the same company, named respectively *Antillean* and *Colombian*, are also under charter, being employed in work between Galveston and Hamburg for the Hamburg American Company's service.

American Steamship Enterprise.

The assumption of the responsibilities of colonial empire have caused the Americans to launch out into shipowning, and consequently into steamship building. So the American-Hawaiian Steam Navigation Company has been incorporated with a capital of £150,000 sterling. Its headquarters will be in New Jersey, and it intends to trade through the Straits of Magellan from New York to San Francisco, and thence to Hawaii. Its operations may be extended to Alaska, America's more northern possession on the mainland. Its first order for two twin-screw cargo-boats of a length of upwards of 400 ft., and of a tonnage of about 8,500 each, has been placed with the Union Iron Works of San Francisco. These vessels are to be ready for work by April of next year. Another similar pair have been ordered from the Roche Shipbuilding Company, of Chester, Pennsylvania. Economy of coal consumption is—as is practically a necessity when the character of the voyage for which they are designed is considered—one of their essential characteristics. The New York and Cuba Mail Company, for which last year Messrs. Cramp, of Philadelphia, built a fine new steamship named the *Havana*, have had a twin-screw mail boat of nearly 6,000 tons launched by the same famous builders. She will be named the *Mexico*, and will have all the latest improvements which characterise modern ships of the highest class. The same builders have contracted with the Oceanic Steamship Company to construct three other twin-screw liners of a guaranteed speed of 17 knots, to ply between San Francisco and Australasian ports. The vessels in question will be of about 6,000 tons gross register, and will, in addition to their coal and passenger capacity have room for about 2,000 tons each of cargo. There is a rumour, however, that, owing to reasons connected with the non-passing of the United States Shipbuilding Subsidy Bill during the recent session of Congress, the work upon these vessels will not at present be pressed forward.

The American Line

has during recent months made its service but a fortnightly one. One of its vessels, the *Paris*, made a trip from New York round the new West Indian possessions of the United States with a party of tourists, and opportunity was taken, whilst ther of its vessels were dry-docked, to fit bilge keels, which will eventually be added to the whole of the fleet, so as to insure steadiness at sea. All the vessels are now at work again, and the regular weekly service is resumed, with one of the fleet advertised as an extra boat once every three weeks, on Wednesdays. The *New York*, leaving Southampton on the 25th March, called at Cherbourg, and her example in this direction will be followed, so that French passengers will be enabled to travel by the American Line without having to cross to Southampton. Arrangements are made whereby week-end trips to the other side of the Channel can be made by those who are fond of comfortable sea trips, facilities being given for the return of such passengers to Southampton by the London & South Western Railway Company's vessels. The only drawback to such trips will be that the time which the traveller can spend on the ocean liner will be all too short.

The White Star Line.

The *Afric* after her maiden trip was sent across to Belfast, where her builders are engaged in increasing her passenger accommodation. The *Germanic* is still at Belfast, having a thorough overhaul, and it will be some weeks yet ere she will resume her place in the mail line. Meanwhile her place is being filled by the *Cymric*, whose only fault seems to be that she has not accommodation for a sufficiency of passengers.

Work on the *Oceanic* is progressing well, and about mid-summer she should be ready to leave her builders' hands. To her has been appointed as chief engineer, Mr. Thomas Wilson Sewell, who is the commodore engineer of the line. This gentleman has had charge of the machinery of all the vessels now running regularly with the mails for these owners, and has previously been in the first *Oceanic* and in the *Baltic*. He has crossed the Atlantic no less than five hundred and twenty-eight times as chief engineer in the White Star Line. His previous experience had been in the service of Messrs. Lamport & Holt. In the new ship he will have a staff of twenty-one engineers under him, the total engineering staff amounting to no less than 182 men, as against 160 in the *Teutonic* and *Majestic*.

The Pavonia

has returned to her work, making her first departure from Liverpool since her accident on the 11th of April. Appreciation of what those in charge of her did in the fulfilment of their duty during her most trying experience has been shown, though perhaps our authorities were more tardy and less gushing than the Germans showed themselves in regard to the officers and crew of the *Bulgaria*. The Cunard Company distributed the sum of five hundred pounds amongst the officers and crew of the vessel. The silver medal of Lloyd's was awarded to Captain Atkin and to Mr. Duncan, the chief engineer, by the Committee. These, and other marks of appreciation, were presented to the officers, at a public meeting held in the Town Hall at Liverpool, by the Lord Mayor (the Right. Hon. William Oulton), who made a very sensible, and not too adulatory, address upon the occasion. The Board of Trade has been approached with a view to inducing the department to grant some recognition to these officers. But the suggestion was not accepted, the Marine Department responding with the declaration that it was not their custom to take any notice of the behaviour, save, of course, in the way of censure, of their certificated officers in regard to the ships with which they were entrusted. This answer is perhaps open to the retort that the sooner this precedent is departed from, the better it will be alike for the Board of Trade, the country generally, and the certificated officers.

No inquiry has been held into the accident to this ship. Yet she must certainly be admitted to have sustained such "serious damage" as would have warranted the Board in ordering one had it been disposed to do so. A very useful purpose might have been served if it had been held, as it would have been very instructive to see whether the mode of securing the boilers in position was that usually adopted, and whether improvements in the method cannot be introduced without serious difficulty.

Within the last few days another vessel, *La Serena*, has been towed into an Australian port in the same condition as regards her boilers. In this case, however, the vessel had been in contact with rocks, and her bottom had been set up to a considerable extent. No blame could therefore under these circumstances have possibly been attached to the mode in which the displaced boilers were secured.

The Milwaukee,

of the Elder Dempster Fleet has become a ship again. Her stranding on the East Coast of Scotland last year, and the heroic remedy adopted for her salvage, will not have been forgotten. Messrs. C. S. Swan & Hunter, who were her builders in the first instance, had the salved portion of the hull returned to them. They placed it on their pontoon dock and built a new fore body to the vessel. This work having been completed, the vessel was launched,for the second time in her short life of under two and a half years, on the 12th April, and she will shortly resume her duty in the fleet, having been re-classed at Lloyd's, and being now as good as she was when she first came out.

Some interesting facts appear in the

Annual Report of the Norddeutscher Lloyd.

The company is prosperous enough—the dividend recommended being at the rate of seven per cent. But with this matter we are not interested, save in so far as we may take it as an indication that German competition with British shipping is not likely to become anything save more keen in the future. The building of big steamers, however—of course on the twin-screw principle—seems bound to go on here. The old *Spree* is coming out shortly as a practically new twin-screw express steamer steamer under the name of the *Kaiserin Maria Theresa.* She will apparently have nothing to connect her with her former self except a short length of her fore body. Why any one should have thought it worth while to sacrifice a good vessel for that passes understanding; but there it is. Two vessels of the size and type of the *Barbarossa* are building for the China service. They are to be called the *Konig Albert* and the *Prinzess Irene.* Two steamers of similar size are building for the Atlantic cargo service, and another larger vessel to be called the *Grosser Kurfurst* is constructing for the New York express service. This latter service will therefore be maintained by the *Kaiser Wilhelm der Grosse*, the present record holder, the *Kaiser Frederich*, which not having come up to the builder's guarantee is not yet accepted, the rejuvenated *Kaiserin Maria Theresa* and the *Grosser Kurfurst*, One might almost suggest to the Germans that it would be wise to make it penal to give vessels names which are three and four barrelled. For it seems as though awful confusion would be certain to arise between the *Kaiser Wilhelm der Grosse* and the *Kaiser Wilhelm II.* and between the *Frederich der Grosse* and the *Kaiser Frederich*, whilst the length of the names now in the fashion with the company contrasts most unfavourably for practical purposes with such names as *were formerly* adopted, such as *Elbe*, *Spree*, *Eider* and *Lahn*. *These latter too being geographical* and patriotic, had much to recommend them to all classes of the German community. There are again three twin screw steamers of 7,500 tons each named the *Kolr*, *Frankfurt* and *Hannover* building for the Baltimore service. As to their nomenclature there is no fault whatever to be found. Only one of all the ships named in building is in a British yard. Messrs. Wigham, Richardson & Co., of Newcastle, have had the good fortune to secure an order for a large twin screw cargo boat; but it is simply through the inability of the German yards to undertake all the work which the great shipping companies of the Fatherland hrust upon them.

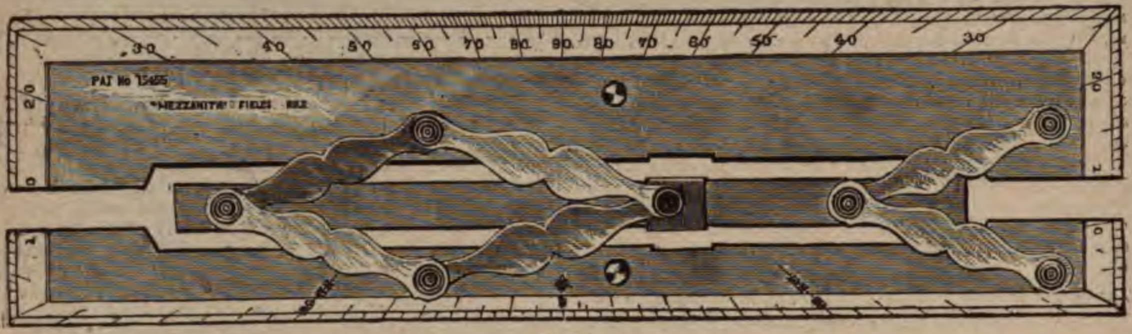


Fig. 1.

THE "HEZZANITH" PARALLEL RULE.

THE objectionable feature which obtains with the ordinary parallel rule consisting of two straight parts or rules, jointed to one another by two connecting rods of equal length pivoted to the rules and parallel to one another is well known, viz., that the progression of the rule over a surface can only be effected in a diagonal line and in one direction only; hence, when the rule is used over a wide range normal to the edge of the rule, a very large margin of room must be available in the direction of the ruling edge in order to use the rule effectively. This feature is entirely due to the construction of the parallel motion of the rule.

Now, navigators and others who have to carry forward parallel lines over large surfaces, such as on charts, will, we feel sure, thoroughly appreciate the benefits to be derived from an instrument which will effect this object in a line normal to the line they desire to carry forward.

We have pleasure in bringing to the notice of our readers a very ingenious, simple, and effective device which is adapted to carry out the above object. In the adjoining diagrams Fig. 1 represents one form of the rule; it will be seen that the two parts of the rule are pivotally jointed by four connecting rods of equal length to an intermediate element, and that the three elements are maintained in a parallel position to one

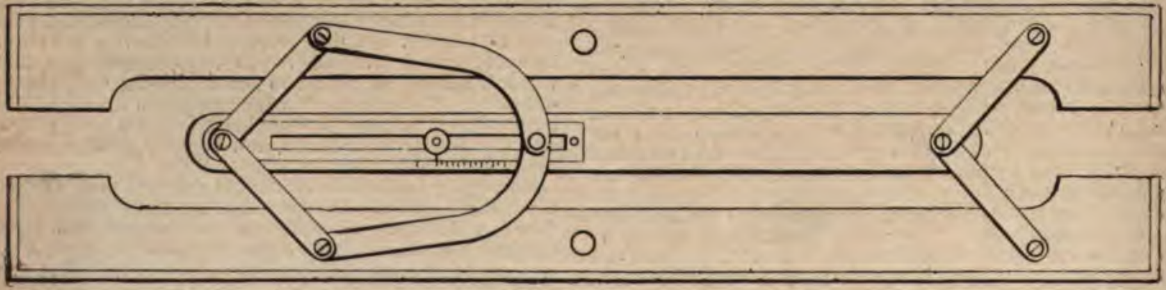

Fig. 2.

another by a sliding sleeve engaged upon the central element, the sleeve being pivotally connected to the two parts of the rule by two connecting rods of equal length.

Now, it will be readily seen that, when the two parts of the rule are moved relatively to one another, the parts are always parallel, and the motion is normal to the edge of the rule.

In Fig. 2 we illustrate a modification of the device in which the sliding sleeve is superseded by the pivot of the middle connecting rods engaging in a slot situated in the central element. The side of the slot is graduated, and an adjustable stop is engaged therein, so that the relative movement of the two parts of the rule can be regulated to a predetermined and definite amount. By this means lines of exactly the same length, and immediately over each other, can be drawn; and, further, the distance between the lines can be regulated at a fixed uniform distance by the adjustable stop.

We feel sure that this useful little instrument only requires to be known in order that its merits shall be widely appreciated by its extensive use.

The manufacturers are the well-known firm of nautical-instrument makers—Messrs. Heath & Co., Limited, of London and Crayford.

BUENOS AYRES HARBOUR WORKS.

At the ordinary meeting of the Institution of Civil Engineers, on Tuesday, the 18th April, Mr. W. H. Preece, C.B., F.R.S., President, in the chair, the paper read was on "Buenos Ayres Harbour Works," by Mr. J. M. Dobson, M.Inst.C.E.

As early as 1862 the late Mr. Eduardo Madero, of Buenos Ayres, had turned his attention to the question of docks for the port of that city, but all applications to Congress for permission to construct a system of docks failed until the year 1882, when an Act was obtained under which the executive Government were authorised to contract with Mr. Madero for the construction of docks and warehouses, together with entrance channels. The docks were to be constructed on the riverside of Buenos Ayres, between the gas works on the north and the Riachuelo river on the south.

On the recommendation of Messrs. Baring Bros, Mr. Madero applied to the late Sir John Hawkshaw, Past-Pres. Inst. C.E., to undertake the engineering, and his firm reported in March, 1884. The report was subsequently approved, and the appointment of Sir John Hawkshaw, Son and Hayter confirmed. A contract for the general work was let to the late Mr. Thomas Andrew Walker; a similar engagement being also made with Messrs. Sir W. G. Armstrong, Mitchell & Co., for the whole of the hydraulic machinery.

In the preparation of the plans, two points had to be carefully studied, viz., the exact position of the docks and the direction of the entrance channel. It was ultimately decided to place the docks parallel to the coast and to provide locks at both ends. With regard to the direction of the channel it was decided to turn it as quickly as possible into the run of the river in order to avoid excessive silting.

The works comprised: A south basin with a water area of 35 acres, and a depth of 21 ft. 3 in. below low water. Four docks connected with each other by passages, crossed by swing-bridges, having a lock at the south end 65 ft. 6 in. wide and 442 ft. 9 in. long, with a depth over sills of 21 ft. 9 in. at low water, and at the north end a lock 82 ft. wide and 508 ft. 4 in. long, with a depth over sills of 22 ft. below low water. The two locks were each crossed by a swing-bridge, and the depth of water in the docks was 23 ft. 9 in. below low water. A north basin, having a water area of 41 acres, with a depth of 21 ft. 3 in. below low water. On the east side of this basin was the entrance to the north channel, which was 100 metres wide at the bottom with slopes 10 to 1. It had been dredged to its intersection with the south channel, a distance of 9·8 kilometres. On the north side of the basin were two graving-docks equipped with all necessary pumping machinery: one dock 600 ft., the other 492 ft. long, each having a depth of 20 ft. over the sill at low water. The total water area of the four docks and two basins was 174 acres, and the length of quays 27,821 lineal feet. Thirteen warehouses had been built on the west side of the docks, having a total capacity of 641,715 cubic yards, and a floor area of 202,751 square yards (41·89 acres). Eight sheds (one bonded) had been constructed, having a total capacity of 122,040 cubic yards, and a floor area of 27,870 square yards (5·76 acres).

The whole of the foregoing works were enclosed by an outer wall nearly three miles long, of which 7,793 lineal feet were of stone construction, the remaining portion being of timber. There were railway lines on both sides of the docks connected with the north and south trunk lines of the Republic.

The docks, passages and lock-walls were all built of rubble masonry of granite, the coping, bedstones, quoins, steps and machinery foundations being of ashlar masonry of granite. In one month alone 17,488 cubic yards of rubble masonry were built, requiring some 26,700 tons of stone from the contractors' quarries.

In order to carry out the works, banks had to be formed to enclose the different sections. At the south end of the south basin, owing to depth of water and the tide, crib-work was constructed so that side-tips could be used, thus depositing the material more rapidly to form the bank. As each dock was completed a timber dam was erected in front of the passage which connected the completed dock with one to be constructed.

The pile-engines used in the construction of the outer wall were the first constructed of their kind. They were really steam hammers, but instead of the hammer-head moving and the cylinders remaining stationary, the hammer-head was fixed and the cylinder struck the blow.

From the entrance of the north basin to Ko. 2·3 the dredging of the north channel was in tosca, with a layer of sand at the top. From Ko. 2·3 to Ko. 4 it was in mud intermixed with sand, and from Ko. 4 to the end the dredging was in mud. The mud and sand were brought and pumped ashore, and the total area filled represented 294 acres. Great difficulty was experienced in landing the tosca dredged, amounting to 651,700 cubic metres.

The channel had six beacons in the length of Ko. 9·8. Buoys were moored every 1,000 metres apart. The channel was not yet completed to deep water. When the plans wereprepared it was intended that the Government, who were dredging the south channel, should complete a channel from the intersection to deep water by the time the north channel was finished to that point, but such had not been the case.

The whole of the bridges, gates, sluices, capstans, cranes, and lifts were worked by hydraulic power.

The graving-dock walls were built of rubble masonry of granite, with altars, copings, steps, &c., of ashlar masonry of granite. In the west dock (first commenced) the invert was built of bricks, but, as it was impossible to secure sufficient bricks to complete the second invert, concrete was substituted. The water was admitted to each dock by two sluices, one on either side of the dock, and with these two sluices the dock could be filled in about twenty minutes. The dock entrances were closed by ship caissons.

The pumping machinery consisted of two centrifugal pumps with vertical spindles, each driven by a balanced compound condensing horizontal steam-engine coupled direct to the pump spindle. The west dock was completed in 10 months from the date of the Act, and the east dock, together with the pumping station, in 15 months. The amount of work done during the 15 months was enormous—including 56,464 cubic metres of rubble masonry alone.

The total area of land reclaimed from the river was 926 acres, of which 561 acres had been made up more or less to quay level; and the total cost of the works was £6,997,360.

Marine Engineers' Examination.—At the recent examination for Extra First-class Engineers, Mr. W. H. Shephard and Mr. Archibald McK. Laird were two of the successful candidates. These gentlemen were students at Leask's Marine Academy, and both passed the first time of going up.

Aspinall Patent Marine Engine Governor. — We are informed that Messrs. David Joy, Son & Pryor, of 85, Gracechurch Street, London, have been appointed agents for the London and Southampton districts for the Aspinall Patent Marine Engine Governor.

FRIEDMANN'S SIGHT-FEED LUBRICATORS. NATHAN (PATENT.)

TO secure a regular, equal, and economical lubrication of the various moving parts in an engine, it is essential that sight-feed lubricators, with multiple independent feeds should be used. Friedmann's lubricators, of which over 50,000 have been sold, are from single to quadruple independent sightfeeding, contents from 1½ pint to 9 pints. Each sight-feed fitted with an auxiliary feed, which may be used in case a sight-feed glass should break, or also to increase the regular feed in case of emergency. The lubricators are entirely of gun-metal, fitted with all necessary cocks, valves, safety arrangements and condensor, etc., and represent a perfect auxiliary for modern engineers.

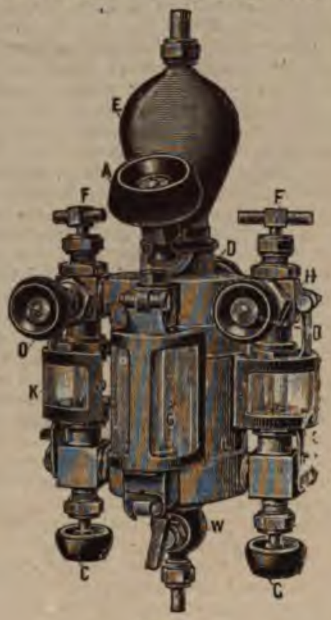

Fig. 1.

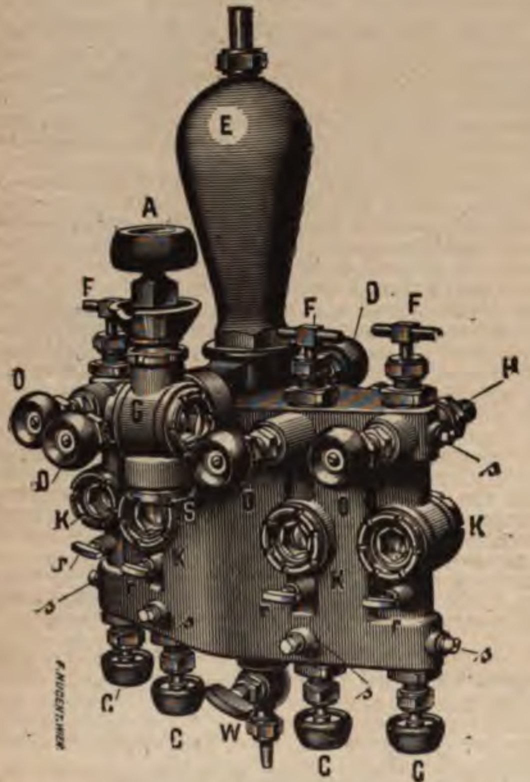

Fig. 2.

In the adjoining illustrations we show the latest types of two patterns of the Friedmann's Lubricators, put on the market by Messrs. Klinger & Co., 66, Fenchurch Street, London, E.C. It will be seen that Fig. 1 represents a double sight-feed lubricator with round glasses, while Fig. 2 shows a quadruple sight-feed lubricator with flat glasses. A is the filling plug, C the oil regulator valve, D the water valve, E the condenser, F the safety valves, G the gauge glass, H the oil pipes, K the sight-feed glasses, J the oil cup, O the auxiliary oilers for use if the sight-feed glass breaks, or to increase the regular feed, W the drain cock, V the valves to clear the sight-feed, and S S are the cleaning studs.

NAVAL ARCHITECTS.

DISCUSSION ON SIR JOHN A. DURSTON'S PAPER.

MR. THORNYCROFT said this was a most important paper, as it was the first occasion on which they had an account of the water consumption of the engines in the ships of Her Majesty's Navy. The paper dealt with the subject in a manner which ought to give them the greatest pleasure. It gave them also the particulars of the working of the engines during the experiment; and the water for auxiliary engines was so separated that they had the water used by the main engines and also that for the auxiliary machinery.

Mr. C. E. Stromeyer thought this was a most valuable paper, inasmuch as it gave them accounts of the large quantities of water used by the main engines and auxiliary machinery separately.

Mr. Seaton said there was very little controversial matter in the paper. He believed it was the custom of the Admiralty to test Belleville boilers on shore. But they seldom were given the evaporative power of the boilers, and if they could have that it would add much to their knowledge, for they could then separate the efficiency of the boiler from that of the engine. The paper showed that the lower the pressure of the steam the better the result. For high speed of piston steam jackets involved a loss, and he had been long of that opinion. They had now obtained from this paper accurate measurements of the water consumption as against the coal consumption per I.H.P.

Sir John A. Durston, in reply, said the water consumption of the auxiliary engines amounted to 3·57 lbs. per I.H.P., or 22 per cent. only of the consumption of the main engines on the trial at 3,600 I.H.P. That figure of 22 per cent. showed the importance of taking the consumption of the auxiliary engines, and they hoped as time went on they would show a better record for these than 22 per cent. of the main engines. The jacketing served the purpose of warming up the engines before getting under way. The air formed a non-conductor between the working barrel and the atmosphere of the engine-room.

Some Steam Trials of Danish Ships. By Captain A. Rasmussen, of the Engineering Department, Royal Danish Navy.

This was a paper on trials of vessels under different conditions. They were undertaken for the purpose of determining (1) the maximum speed, the full power speed, and the sea speed at normal draught and at a standard depth of water (6 fathoms for small vessels, 8 for larger ships); (2) speed trials for the determination of the curves of H.P. and revolutions at normal draught and at different depths of water; (3) speed trials for the determination of the above-named curves at the standard depth of water and at different displacements; (4) coal consumption trials for the determination of the most economical use of the propelling machinery with different numbers of boilers and engines in use; (5) trials for determining the time necessary for raising steam and getting under way; (6) determination of the power of the propeller to decrease and increase the speed of the vessel.

Sir Wm. H. White was sure the feeling of every member of that institution was one of gratitude to Captain Rasmussen for giving that paper, the preparation of which was entirely due to himself. Captain Rasmussen, about five years ago, gave in *Engineering* the results of similar trials. The Danes had a good reason for making these trials about their coasts. They had large stretches of shallow water. He thought the results were of more scientific interest than practical application. From the diagrams, it appeared that at speeds from 12 to 15 knots per hour the expenditure of power was extremely great in proportion to that at more reasonable depths. The trials to determine the influence of displacement on speed confirmed our modern practice.

Mr. Thornycroft was interested in the paper because the vessels referred to in it were built by his firm. He had always thought it dangerous to have windows in the boilers, but he was glad there had been no accident as yet.

Mr. Macfarlane Gray was interested in Fig. 1 of the paper, which was a diagram containing curves of slowing speeds. He had been searching for years for such information, and was glad he had found it. It had great importance in reference to collisions at sea. He would be glad to know in what space vessels could be stopped or reversed.

Sir E. J. Reed said he would like to know the character of the bottom of the vessels used in the trials.

Mr. Martell asked whether a vessel was influenced by the action of the earth at the bottom of the sea when it was travelling in shallow water. Water, they knew, pressed with equal force on a ship from any direction. Did the earth attract like the planets.

The Machinery of Warships—Twin v. *Triple Screws.* By Commodore George Melville, Engineer-in-chief of the United States Navy.

It was read by Lieut. Norton. He said, in the preparation of a set of tables, showing the force required to drive a vessel of a given displacement at a given speed, data had been used which were gathered from the results of about 200 trials of nearly as many ships. It was shown that the propulsive efficiency of vessels with three screws was in almost every case above that of ships approximately the same size, speed, and general lines, but fitted with only two sets of engines. The cruisers *Columbia* and *Mineapolis* had shown themselves superior in efficiency and speed to other vessels, in consequence, mainly, of having three propellers. Other factors were the greater safety of the machinery of the ship, due to the use of three screws. Smaller propellers were required for the same total power. Of full-power trials, from the economical standpoint, it was best to use a single screw. Beyond this point the use of twin screws would lead to a reduction of the power required for a given hull and maximum speed; and at any time where twin screws were good, triple screws were better. His estimate of the average economy of twin screws over single screws was about 8 per cent. for vessels of maximum speeds from 12 to 20 knots, and triple screws were more economical than twin screws by from 5 per cent. for 15-knot ships, to 12 per cent. for those of 24 knots speed. Taking a vessel of, say, 12,000 tons, 23,000 H.P., and 22 knots speed when all engines were used at full power—(1). The power required to drag one screw, uncoupled from the engine and left to revolve freely, was 150 H.P. at 10 knots, 600 H.P. at 15 knots. (2). If coupled to the engine at 10 knots speed, the power absorbed in dragging was slightly in excess of 300 H.P. (3). If two screws were dragged, the loss from drag was practically double what it would be with an idle screw for the same speed of ship. (4). The loss in power due to condensation in an engine was almost exactly one pound of steam in the cylinders for each H.P. of the maximum power for each engine. It applied to jacketed engines. (5). With three equal screws the entire propeller had not sufficient area to give economical results when used alone at speeds above 8 knots; and the use of the two wing propellers alone could be depended upon to give a considerable gain in economy for all speeds from 8 to 17 knots inclusive.

Mr. Seaton acknowledged the indebtedness of the institution to Commodore Melville, but thought that he had in emphasising to the utmost the advantages, and minimising to the utmost the disadvantages, of the triple-screw had proved too much. Forty years ago, during the time of the Crimean war, the triple screw was tried in a vessel in the British Navy. The trial was accidental, but it was resorted to for one of the reasons urged by Commodore Melville for the adoption of the triple screw. A single-screw floating battery built at that time developed such a very poor speed that something had to be done, and the authorities came to the conclusion that the fault was due to the smallness of the screw. As her draught did not permit her having a larger screw it was decided to put in two wing screws driven by gearing from the original main engines. Any improvement of speed obtained from the three screws would be completely eaten up by the friction of the wheel gearing.

Professor Miles did not attach much weight to the advocacy of the triple screw on transatlantic ships, on the ground of greater security in case of such an unusual circumstance as the complete break down of both engines.

Sir Wm. White said the paper contained very few facts, and they could not discuss the question of the relative merits of the triple and the twin screws on the basis of recorded facts. He knew more than he could at the moment say—exact information of the scientific character, not worthy of triple-screw steamship performances, but of the comparison of such performances with model experiments. He could say he knew of no facts to establish the contention that "the use of triple screws leads to a considerable economy at the highest speeds." Was it not a suggestive fact that after being introduced to arrangements (1) of triple screws of fairly equal size; (2) of a very small screw in the centre and two large screws at the side—a system which had been boldly tried in Russia—they were introduced to (3) a large screw in the centre and the two small screws at the side? But we must certainly look forward to higher speed; and we had to accept limitations of draught. Therefore if present propelling arrangements and present types of machinery were persisted in, and unless some more radical changes took place, the time might not be long before for certain classes of ships triple or multiple screws would become the rule.

Lieutenant Norton said he knew Commodore Melville had the authority of fact for the conclusions set forth in the paper, and, no doubt, he would before the transactions were printed be pleased to furnish the facts to the Council.

Stresses in a Ship's Structure. By Mr. J. Bruton.

He discussed the break in the continuity as represented by the end of a bridge. He shows the shearing strain of the hatch corner to be 3·09 times greater than the mean full strain across a section in way of the hatchway. He also discussed the late Professor Jenkins' views in which he stated the shearing stresses on the deck plating were very small indeed.

Mr. Martell said in dealing with vessels of general construction where continuity of strength was maintained throughout the length of the ship up to the gunwale, Lloyd's experienced no difficulty, such ships with the ordinary framing and building provided for could take care of themselves. Great difficulty was felt in meeting the problems arising out of new stresses brought to bear and the symptoms of weakness exhibited at the junctures were those erections were made. Another serious matter prominently brought forward in the paper was the continued extension in the size of hatchways in ships of the present time. Lloyd's were frequently urged to make allowance for steel or iron decks, but when looked into it was found that those decks were cut away by enormous hatchways, often two-thirds the breadth of the deck.

Professor Biles said the question of stresses had been a constant worry to believers in the girder theory. There were two methods of dealing with the question, one was by having no discontinuous points in the structure, the other method was to strengthen the discontinuous points sufficiently to resist extra stresses brought to bear on them. An attempt was now being made to make the bridge-deck long enough, and strong enough, to resist the main stresses of the ship, but he thought it was worth consideration to try to disconnect the bridge-deck horizontally from the main structure of the ship, rather than to attempt to make the points of discontinuity strong enough to resist the stresses that came upon them.

Discussion on Mr. Milton's Paper.

Sir John A. Durston said as far as the Admiralty was concerned, many of the points dealt with were insisted upon in the specifications. The latest requirement specified for in regard to the use of steam pipes was that pipes above 1½ in. diameter should be made in steel, and those below in copper solid drawn. Steel pipes up to, and including, 9 in. in diameter were to be solid drawn, while above that diameter they were preferred to be solid drawn; but might be welded with a butt strap over the weld.

Mr. Seaton said the best they could do with their old copper pipes was to take them out and put steel ones in their place. Mr. Martin, of Flushing, made his pipes as we should a hollow shaft, formed them out of the solid, and the cost was not greater than that of copper pipes. The fear that the steel pipe might corrode on the inside, had deterred a great many engineers from selling their copper pipes and substituting steel ones. After very many years' experience of wrought-iron, cast-iron, and steel pipes, he had found practically no damage of any kind on the inside.

Mr. List said the number of cases in which his firm had had to take out pipes a few days before sailing was quite remarkable. He had fitted copper pipes in straight lengths with expansion joints and bound these with copper wire. They had not caused the slightest trouble. The pipes used by his firm had cast-steel flanges screwed on in all cases, and no trouble from leakage had occurred in any of the flanges in the experience of four or five ships. It was found after three or four years' use that there was a brown deposit on the surface, probably a little oxide, but there was no corrosion. He did not think it was necessary to periodically take down copper pipes and anneal them. If the pipes were tested every four or five years by hydraulic pressure it would be sufficient. Wrought-iron pipes were a good deal cheaper than copper ones, but the stuffing-boxes and other arrangements brought up the expense.

Mr. Wingfield exhibited a piece of copper on which his foreman coppersmith had allowed two drops of tin, heated over a blow-pipe, to fall. One drop had gone right through the copper, leaving a hole, while the other had embedded itself in the copper. Tin was thus an undesirable alloy.

Mr. Milton said the question of soldering material had been gone into very thoroughly by Professor Arnold and himself. He had found on enquiry that half the manufacturers used half per cent. of tin. He found nearly all solder manufacturers kept close to 50 per cent. of copper and 50 per cent. of zinc. respectively. He had seen common brazing solder go right through a ⅜-in. pipe.

Portable Pneumatic Riveters,

by Mr. W. J. Badcock, was read by the Secretary, Mr. G. Holmes. He said, as Manager of the Chicago Shipbuilding Co., he had after experiments introduced machinery, capable of being operated by unskilled labour, by which all the rivets in a ship could be driven, which had been entirely successful and, in the last ship which was completed, 250,000 rivets were so driven out of a total of 340,000, and but for insufficient air supply the proportion would have been greater. They used a pneumatic hammer, consisting of a cylinder, in which a piston reciprocated, delivering almost a continuous series of blows against the end of the chisel, caulking tool, or rivet die. The hammer was light and powerful, short enough to go between frames, and small enough to get at rivets in corner angles.

The Strength of Boilers.

by Mr. C. E. Stromeyer, Chief Engineer of the Manchester Steam Users' Association. He said they did not yet know what the collapsing pressure of a furnace was. He gave the per centage of strength for a rivet seam to be

$$B = \frac{1{\cdot}26\ (l-d)\ \tfrac{3}{4}\ d\ \tfrac{1}{4}}{l}$$

He took cases of floors which collapsed under pressure, and examined their strength in the light of formulæ and found they were sometimes as much as 113 per cent. too strong, and in other cases 40 per cent. too weak. He discussed the plates for an oval-shaped furnace, slab plates, firebox, crown girders, tube plates for feed heaters. The paper had a long appendix giving the results of numerous tests.

Mr. Milton said the author stated, "In conclusion, I beg to say one word with regard to my use of Lloyd's formulæ for boilers. The engineering members of this Institution are more familiar with these rules than with any others, and naturally would compare them with any experiences which are laid before them, and Lloyd's Register will, I hope, be pleased at seeing their rules set up as a universal standard of comparison." Yet wherever else in the paper, Lloyd's rules were referred to, they appeared to be mentioned to show they were incorrect. He really must take exception to such a position. The experiments made by the Leeds Forge Company, and other firms, were not perhaps made with tubes "almost mathematically cylindrical," but they dealt with other matters as they were in ordinary furnaces, with the sole object of obtaining knowledge of the strength of the furnaces actually to be used. Dealing with the statement that "occasionally moral pressure on the part of shipowners and engineers, had resulted in a reduction of scantlings," Mr. Milton said he joined the staff of Lloyd's Register 24 years ago, and was cognisant of every reduction of scantlings which had been made. The initiative in these cases had usually been taken by officers of Lloyd's Register, while at the present time Lloyd's Register had the benefit of the advice—not the moral pressure—of a consultative body of engineers and shipowners, on whose experience the modification in the rules is based.

Mr. Stromeyer hoped that even the results of the experience which he had put before them, like the knowledge of other outside science, might be found useful by marine engineers. So far from wishing Lloyd's to alter their rules or do anything hasty in that direction, he maintained that his paper did not in any way advocate that they should be departed from. Everything at sea depended on insurance rates. Lloyd's had never had an explosion, and the insurance world looked to Lloyd's Register as a guide on the subject of the safety of ships and their machinery. The information given in the paper had been given for the purposes of comparison with Lloyd's Rules.

Sir Edward Reed said it was perfectly clear the paper had been written in absolutely good faith, and that the council had seen in it ample merit for its production.

Mr. Howden read a paper on "Torpedo Boat Destroyers for Sea Service," and Mr. James Hamilton "On the Communication forwarded by Messrs. J. Inglis and A. Denny and Professor Biles on the subject of Mr. James Hamilton's paper on the horse-power absorbed by Skin Friction and Wave Making."

Professor W. E. Dalby read a paper on "The Balancing of Engines, with Special Reference to Marine Work." He said it was to explain and illustrate a semigraphical method of treating balancing problems in a direct and simple manner. He showed how to obtain a simple formula for finding the best distribution of the mass of the connecting-rod between the revolving and reciprocating parts. He showed how to ascertain the resultants of the disturbing forces and couples for a system of masses revolving about a fixed axis, how the resultant force and resultant couple might be reduced to a Poinsot's central axis for purposes of comparison. The conditions of balance were stated in a geometrical form. He showed that the motion of a system of revolving masses in balance might be projected on a plane, and the projected simple harmonic motion would be in balance; and inversely assuming a system having simple harmonic motion, its balance might be investigated by translating the motion into a corresponding circular motion. He finally showed the balancing of a four-crank engine, neglecting the angle of the connecting-rod.

Professor Dunkerley said he would like to ask if the calculated masses were at all approximate to the actual masses, such as might be expected to be found, or whether there was considerable alteration necessary; and if the designers would, before the engine was in the ship, trouble to so arrange their masses as to guarantee in the absence of obliquity a perfect balance. To solve the problem only three masses were required. If they had four reciprocating masses given, the problem was indeterminable; they had got too much, and in ninety-nine cases out of a hundred there would be no exact solution.

Professor Greenhill said the subject was familiar by reason of the paper of Mr. Macfarlane Gray. He was sorry that gentleman was unable to be present. About 30 years ago it was thought a crank axle in a locomotive would very soon become a thing of the past. While it had never appeared in America, it was gaining ground in this country. The superiority of the crank axle consisted entirely in the diminution of the disturbing mass moments, as Professor Dalby's explanations and the experiments with the model had shown. Hitherto, it seemed as if attention in balancing had been devoted to bringing the centre of gravity into the line of the axle, so as to annul disturbing centrifugal force, ignoring as apparently intractable those transverse disturbing moments. He thought it would be worth while striking a compromise, leaving a certain amount of unbalanced centrifugal force in the axle of the locomotive engine, and with that latitude striving to diminish the products of inertia in mass moments.

Mr. Thornycroft said one felt after hearing the paper that they could balance an engine in five minutes. He could not quite agree that the difference of one-ninth of the maximum force of the moving masses was so small an item as not to be taken into consideration, and was rather afraid a disturbing force of that amount caused real trouble in a ship. The practice of his own firm to avoid the niggling of the ship by the turning moments had been to put the cylinders as near together as possible. If equal forces were put as nearly opposite as possible, the disturbing forces were to a large extent eliminated.

Sir William White, as one of those who had to do with building ships, said he should hope they were all agreed that it could not be good either for the engine or for the ship to allow the causes of vibration to remain any longer than they need be. From a naval architect's point of view, he regarded the placing of a badly balanced engine in a ship as nothing less than an outrage. To be compelled to adopt a largely increased strength of structure to stop a thing which never ought to begin was certainly a wrong way of working.

Professor Dalby said the introduction of properly balanced engines would, no doubt, largely increase the patronage of passenger ships, minimising, as they would, the discomforts of over-sea voyages.

THE X.L. ADJUSTABLE LATHE MANDREL.

WHEN turners wish to turn anv piece of metal concentric with a cylindrical bore of small dimensions they fix the metal on a solid cylindrical mandrel. This mandrel has a slight taper, and the piece to be turned is forced on to the mandrel. The adjustable mandrel we illustrate simplifies the fixing of such greatly, and entirely prevents any injury to the cylindrical surface to be held, and also possible injuries in the process of forcing on.

The mandrel consists of two parts only—a tapered screwed plug and a flexible round nut. This nut is cylindrical and flexible on the outside, and tapers like the screw. A larger eye can be fitted by using a parallel cylindrical flexible sleeve, slotted in the same manner as the nut and placed over it. The screw and nut are made of best steel, thoroughly case-hardened and practically unwearable. They are lighter than the solid mandrel, and are more easily fixed. Thin tubes or bushes may be turned on them without injury. They are being adopted in Messrs. Yarrow and Co.'s and many other engineering firms. They are made from one inch up to twelve inches diameter, and are sold by Messrs. John Turnbull, Junr., & Sons, of 39, Victoria Street, Westminster, London, and 18, Blythwood Square, Glasgow.

FRIEDMANN'S PATENT RESTARTING INJECTORS. 1899 PATTERN.

WE have the pleasure to place before our readers the latest patterns of the well-known Friedmann's Injectors, of which 160,000 are in use. Friedmann's injectors, 1899 pattern, are fitted with the latest and most modern improvements; every care has been taken to get an article scientifically as well as mechanically perfect. The main features for which these injectors have been designed are:—1st, that should the admission of steam or water be interrupted from any temporary cause, the injector will restart itself as soon as such cause of interruption has ceased; 2ndly, that the injector shall work steadily, and without the least loss through the overflow after the steam valve has been fully opened; 3rdly, no regulation required should the steam pressure and temperature of feed-water vary, thus reducing attention to a minimum; 4thly, simplicity in construction, involving great ease of cleaning; and, 5thly, that the quantity of water delivered shall increase with the boiler pressure. These injectors have no moving parts and will take very hot water. However, the greatest advantage of these injectors is the *enormous quantity of water* they deliver in contrast with all other injectors. Friedmann's injectors deliver at a return pressure of 200 lbs., a far larger quantity than at a steam pressure of 100 lbs. This feature cannot be over-estimated, as there is a clearly increasing tendency to raise the steam pressure. In the adjoining diagrams we illustrate in Fig. 1 a front elevation of the vertical combination injector; Fig. 2, a side elevation; and Fig. 3, a sectional front elevation of the same. Figs. 4 and 5 show similar views of another pattern.

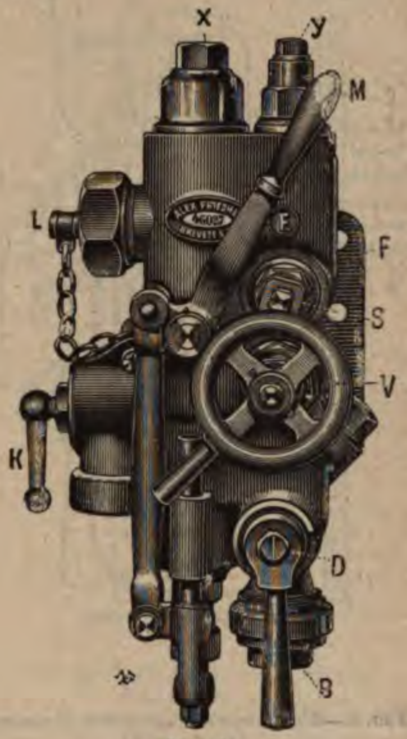

Fig. 1.

In these illustrations it will be seen that A is the steam inlet, B the water inlet, C the water delivery, D the water regulating valve, F the flange for mounting the injector, K the overflow valve, k the overflow pipe, M the starting lever, S the boiler check valve, Y the back pressure valve, X the cap for removing the covers, and L the union for fire hose connection.

We understand that the range of regulation in working is over 50 per cent.; the injector can therefore be worked continuously or intermediately.

These injectors are put on the market by Messrs. Klinger & Co., of 66, Fenchurch Street, London, E.C., who have just issued a new catalogue, illustrating and clearly describing the various specialities they sell. They include in this catalogue some extremely interesting facts with reference to the function of the various devices in comparison with others in the market.

NAVAL MATTERS—PAST AND PROSPECTIVE.

(From our own Correspondents at home and abroad.)

Contracts and Penalties.

AN old question has once again come to the fore, that is, the delivery of vessels by contractors long after the time specified by the Admiralty. In a letter to the *Morning Post* on this subject a correspondent points out that in the case of a destroyer which ought to have been completed four years ago, the penalties would have amounted to £23,000, if they had been enforced by the authorities at Whitehall. Other instances are given of destroyers which have been sadly behindhand in delivery, and the writer argues that the penalty clauses should be enforced. It would be folly, however, if it were not left entirely to the discretion of the Admiralty to settle whether this should be the case, for special circumstances often arise making it impossible for the contractors to complete the vessels in the stated time. The engineering dispute for instance, was responsible for a great deal of delay in the delivery of vessels, and if the Admiralty had enforced their rights at this time, the mischief caused by the strike would have been still further increased. The question, it will be remembered, was raised in Parliament some time ago, and, in reply, Mr. Goschen said that the Admiralty had no desire to penalise the contractors, or to fine them for having failed to complete contracts which could not, in the special circumstances, have been completed. But it is not right to put down all the delays to strikes, and, when it is no longer possible to advance this matter as an excuse for breach of contract, the contractors should not be allowed to escape so easily. It should be remembered that the penalty clause has at least one excellent effect, if it is not allowed to become a dead letter; it deters those from contracting at cutting prices who in the public interests are best kept out of the competition.

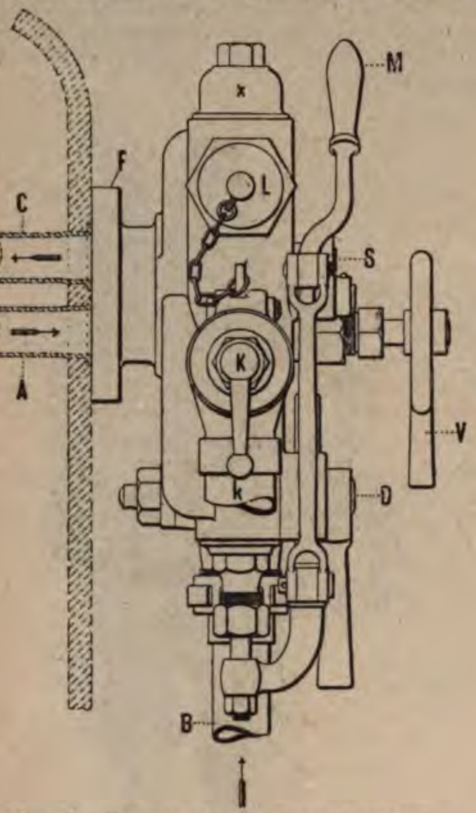

FIG. 2.—FRIEDMANN'S RESTARTING INJECTORS.
(*See page* 69.)

Portsmouth Dockyard.

There is little doubt that the *Terrible* will have to undergo a considerable overhaul before she is once again ready for sea. New boiler-tubes will have to be provided, for it is clear that all the welded-tubes will have to be taken out of her, and weldless tubes substituted. It is a pity the *Terrible* cannot be sent for a spell of foreign service, as this would probably do more towards getting her into proper working order than all the tinkering at the hands of the dockyard "maties." Her sister-ship, the *Powerful*, has just made a record run from Hong Kong to Manila without the least mishap, which speaks very highly for those in charge of her machinery department. It will not be long now before the *Andromeda* and *Gladiator* are ready for sea, and the steam trials of the *Canopus* will most probably take place in two or three months' time. As regards the other ship in hand, the *Pandora*, she is taking shape very rapidly, and also the *London*, but this battleship would get on much faster if more hands were employed upon her. Work on the *Formidable* is not progressing quite so rapidly, as the dockyard authorities have had to wait a long time for the Admiralty to decide on some minor details of her construction. The scheme of shore defence for Portsmouth, commenced here last year, is being continued, for it is now settled that about 20 or 30 12-pounder quick-firing guns are to be mounted on the shore at Stokes Bay. Portsdown Hill forts are to have the same number of guns mounted. The *Alexandra* is now in dock here undergoing her annual refit.

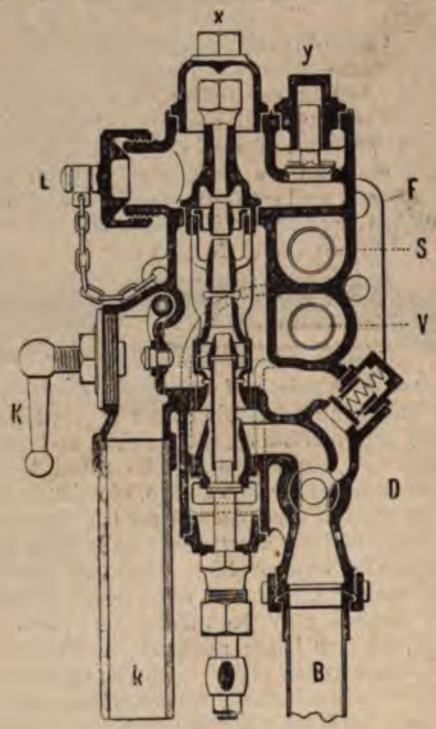

FIG. 3.—FRIEDMANN'S RESTARTING INJECTORS.
(*See page* 69.)

The Promise of the Estimates.

Turning to the other side of the question, it seems that a great deal of arrears of the work caused by the dispute in the engineering trade in 1897 is to be made up, for it is promised that five battleships, fourteen cruisers, seven unprotected vessels, and twenty-four torpedo-boat destroyers will be passed into the Fleet Reserve before the end of the financial year, 1899-1900. The battleships are the *Albion*, *Canopus*, *Glory*, *Goliath*, and *Ocean*, and the cruisers include the *Andromeda*, *Spartiate*, *Ariadne*, and *Amphitrite*; the *Gladiator*, *Hyacinth*, *Highflyer*, and *Hermes*; *Pandora*, *Pioneer*, *Pyramus*, *Perseus*, *Prometheus*, and *Pomone*. Of the unprotected vessels the most important is the Royal yacht, which is to be launched on the 9th of this month, and the other vessels are the sloops *Condor* and *Rosario*, the gunboats *Bramble*, *Britomart*, *Dwarf*, and *Thistle*. The trials of these vessels must certainly arouse considerable interest, for several of them represent new classes. Almost all are fitted with Belleville boilers, and five machinery makers are represented, Messrs. Maudslay, Lairds, Penn, Hawthorne, and the Greenock Foundry Co. During the year six ships are to be launched, and the same number of armoured ships commenced, in addition to three third-class cruisers and two sloops. This, it must be admitted, will be a good year's work, especially when compared with the previous financial year, in which only ten protected cruisers and twenty-one destroyers were added to the effective list. To man all the vessels which it is anticipated will be passed into the Fleet Reserve would require a good deal more than ten thousand officers and men, for the five battleships alone will require a complement of 3,750.

Comparisons of Naval Programmes.

Some interesting facts relative to the amount of money which is spent every year on the navies of the various great Powers appeared recently in a daily contemporary. The figures given endeavour to show, by a comparison of the naval expenditures of the great Powers for the last ten years, that we are still a good deal behindhand as regards the naval construction of this country and its rivals on the sea. We are informed that during the last ten years the expenditure on naval construction averaged sixteen millions a year, which was not quite so much as the amount expended by France and Russia combined. This way of looking at the question, however, is not exactly the right one, for it is well known that in Great Britain the naval authorities get better value for their money than do the navy departments of other countries. In much the same way the writer makes out a table showing the relative strength of Great Britain, France, and Russia in battleships, cruisers, torpedo boats, &c., but omits to state that France and Russia have a great many more old-fashioned and practically useless vessels than this country; for instance, he shows that in battleships we are four behind our two rivals, that we have two armoured cruisers less, fourteen coastguard ships less, four torpedo cruisers less, and one hundred and seventy-seven torpedo boats less; the only vessels in which we have any preponderance being, what the writer styles, "ordinary cruisers," of which we have a majority of fifty-six, and torpedo-boat destroyers, of which we have a majority of one hundred and four. However, such articles as these help to keep up the interest of the public in the Navy, for if only optimistic views were taken of our naval strength, it would not be very long before the need for another Navy League would be felt.

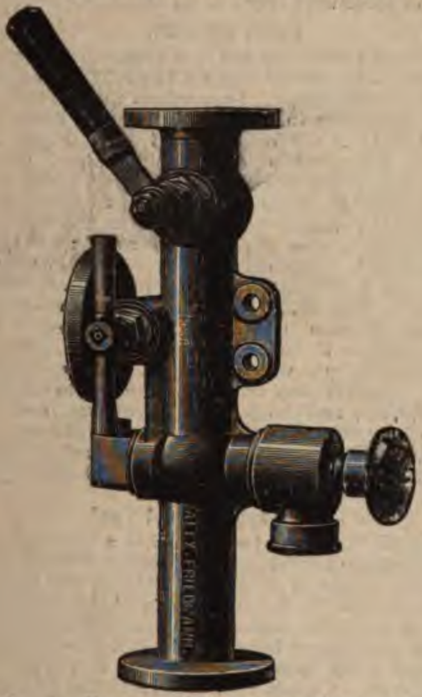

FIG. 4.—FRIEDMANN'S RESTARTING INJECTORS.
(*See page* 69.)

Devonport Dockyard.

The various vessels under construction at this yard all continue to make good progress. The *Bulwark* has not had so much material worked into her as had the *Implacable* when she had been on the slip a corresponding length of time, but this is chiefly due to the bad weather which has been experienced, as the men had some difficulty in working in the gales and storms. Her rate of progress, however, is rapid, and she is not likely to be delayed by the non-delivery of castings, as the stem-piece was unshipped here over a month ago. The competition which existed between the various yards 12 months ago is, to all appearances, not being repeated in the case of the *London*, *Bulwark*, and *Venerable*. Never before have three battleships been building at this yard simultaneously. The *Ocean*, however, will shortly leave here, as she is being prepared for sea as rapidly as possible. Some trouble has been experienced in obtaining a sufficient number of skilled mechanics, and this state of affairs can only be remedied by the Admiralty doing away with some of the restrictions and increasing the pay of the men. A sad accident happened at the Keyham Factory a few days ago, which resulted in the death of Harris Brown, a first-class student. It appears that he was tampering with machinery which he did not know much about, and no one in authority being near to stop him he continued to do so with fatal results. A student who is making his mark at this place is Mr. Percy Goodyear, who entered the college in 1895 as an engineer student. He gained the highest number of marks in advanced mathematics at the last examination, and thereby carried off the prize. The *Collingwood* narrowly escaped ramming another vessel, the *Traveller*, in the early part of last month. She was, however, prevented just in time.

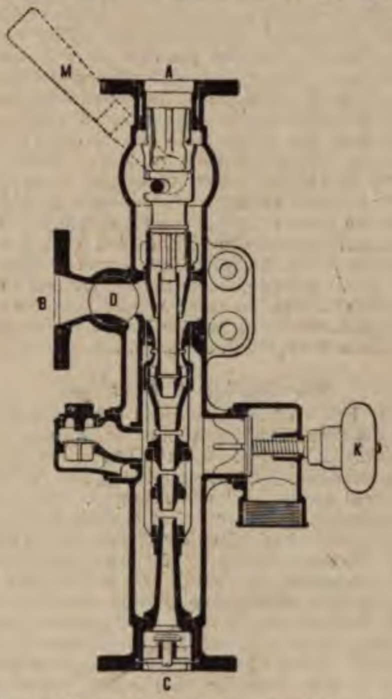

FIG. 5.—FRIEDMANN'S RESTARTING INJECTORS.
(*See page* 69.)

The Speed of Torpedo-boat Destroyers.

The speed of torpedo-boat destroyers is rapidly on the increase. The preliminary steam trials of the new torpedo-boat destroyer *Albatross*, on the Maplin Sands, a couple of weeks ago, showed that this boat is capable of steaming at a speed of more than thirty-two knots, or about thirty-seven miles an hour. Messrs. Thornycroft are the builders of this fast vessel, which is practically an experimental boat, one of several which were ordered by the Admiralty about eighteen months ago. The weather at the time of the trial was very squally, but, in spite of this, a mean speed of 32·294 knots was obtained on the measured mile. The *Albatross*, however, was on this occasion running with the wind and tide, and when she steamed back against the tide and in the teeth of the wind her speed fell to 30·303 knots. In all the circumstances this was very good, and the builders are to be further congratulated on the fact that no mishaps occurred to the engines or boilers. The *Albatros* is 227 ft. in length, has a beam of 21 ft. 3 in., and a draught of

8 ft. 6 in. Against this excellent record, however, must be placed the trial of the Chinese torpedo-boat destroyer, *Hai Lung*, a vessel built by Messrs. Schichau, of Elbing This boat is 193 ft. 6 in. long, has a beam of 21 ft., and displaces 280 tons. At a trial in the open sea, with all weights on board, and 25 tons of coal, this vessel made 35·2 knots, a little more than forty miles an hour. This, however, was with forced draught, for with natural draught and sixty-seven tons of coal on board, the *Hai Lung*, only made thirty-one knots. But there is still a chance that we may have a faster boat than the Chinese torpedo-boat destroyer when the first of the new *Turbinias* takes the water. The original *Turbinia*, it should be remembered, was only a quarter the size of the *Hai Lung*, and yet made thirty-five knots. In addition to which we do not yet put great faith in foreign trials.

Naval Works.

It has at last been decided to commence work on the new naval barracks at Portsmouth, and the contract for the work has been given to Messrs. Lovatt & Co., who are to commence operations immediately, and complete the work in three and a-half years. Sixty-two and a-half acres are to be taken up by the new buildings, which is probably the largest area of ground used for the purpose in Great Britain. The cost is to be £400,000, and when completed the new barracks are to accommodate 5,000 men. The old Anglesea barracks are not to be pulled down, but the inside is to be practically rebuilt. The present Station Hospital is to be removed to make way for the officers' quarters, but before this can be done a new station hospital is to be built on Portsdown Hill. Taking into consideration the fact that it is now three years ago that two and three-quarter millions sterling was set aside for this and other naval works, the same amount in 1897, and that the total payments for the three years ending March 1st, 1898, gave an aggregate expenditure of £2,126,747, there seems to have been some delay in completing the contracts for the various works. The amount expended should be more nearly approximate to that estimated, or the conclusion is forced upon us that more money is asked for than is required, or that it is asked for before it is wanted.

The Docking of Warships.

The return home of the first-class battleship *Victorious* has brought to the front the question of docking accommodation for ships on foreign service. On the China station the largest dock is that belonging to the Hong Kong and Whampoa Dock Co., which will easily hold the *Powerful*, but, in the opinion of the commander-in-chief on that station, is not quite wide enough for the *Victorious*. In view of this the statement which was made at the annual meeting of the company mentioned by the chairman is most interesting. He stated that the matter of docking vessels of extreme dimensions had occupied the attention of the directors for some considerable time, because it was found very difficult to provide the necessary accommodation required for many of the larger vessels now trading to the port. With a view, however, to meeting immediate wants it had been decided to lengthen the Admiralty dock fifty feet at an approximate cost of about 25,000 dollars, and while this work was being carried on the dock would continue to be available for docking purposes. He stated that it was of the utmost importance that they should possess every facility for docking the largest merchant vessels, for that otherwise the accommodation would be provided elsewhere, and would be the means of bringing keen competition into their business. He also stated that, as the larger type of vessels were increasing in number, the time was approaching when they would have to recommend to shareholders the necessity for constructing a new dock on the same lines as the Admiralty dock, but having a length of 750 feet on the blocks. This is good news, but if the intelligence from America to the effect that by electro-plating the bottoms of vessels docking can be dispensed with for an indefinite period be correct, then the necessity for new docks abroad will to a certain extent, disappear. But this news must be accepted with all reserve. If it is true, an enormous saving in money would result in the long run, and ships would not have to be withdrawn from places where their services are likely to be needed for the purpose of being docked, as in the case of the *Victorious*, The bottom of a small vessel might be electro-plated as a test.

Sheerness Dockyard.

Of the ships building and completing here the *Pomona* has not yet passed into the Reserve, although she is on the point of doing so. She is to be commissioned for service on the East Indies Station on the 18th of this month to take the place of the *Redbreast*. She has concluded the whole of her trials successfully, but has yet to go to Chatham to have her underwater fittings examined. The *Pomona* has proved herself the fastest cruiser of her class, as it will be remembered she made 20·2 knots under very bad weather conditions. The *Warspite*, upon which a considerable sum has been spent during the past three months, has at last left for the Pacific Station. Nine years ago she left this place for the same station, on her first term of service afloat, flying the flag of Admiral Hotham, and under the command of Captain the Hon. Hedworth Lambton. The *Edinburgh* has taken the place of the *Sanspareil* at this port as the flagship of the commander-in-chief, and the *Sanspariel* is to be at once taken in hand for repairs, and will not be able to resume her place as guard-ship until the end of next month. The repairs necessary are mainly connected with her machinery and boilers. On the 4th of this month the *Partridge* once again hoists the pennant. She is to leave on that date for the Cape of Good Hope and West Coast of Africa Station. The repairs on her have included a number of her bottom frames being replaced, as a number of these were found to be defective.

Refits for 1899.

The financial year which has just commenced promises to be a particularly busy one as regards the refit and repair of warships at home and abroad. In previous numbers the names of the vessels which are to be taken in hand at home have been given. Abroad, the *Revenge*, *Royal Oak*, *Royal Sovereign* battleships, the torpedo depot ship *Vulcan*, the gunboat *Cockatrice*, and special-service vessel *Imogene*, are all to undergo repairs or refits at Malta. Close upon £9,400 is to be spent upon each of the battleships, and £7,300 on the *Vulcan*. £5,920 is also to be spent upon the *Centurion* at Hong Kong, and the store-ship *Humber*; the sloops *Algerine* and *Phœnix* and the surveying vessel *Waterwitch* are also to be dealt with at this place. At the Cape £2,850 is to be spent upon the *Monarch*, and the gunboat *Widgeon* is to have a refit. Turning to Bermuda, only one vessel is to be taken in hand at this place. This is the *Indefatigable*, upon which £6,400 is to be spent in refitting her. In Australia the cruiser *Tauranga* is to be repaired at a cost of £4,800, and the gunboat *Karrakatta*, and the sloop *Torch* are also to undergo refits, the *Karrakatta* at a cost of nearly £3,000. Esquimault is also to have its share of work, for the surveying vessel *Egeria* is to have £1,690 spent upon her at this place.

The Supply of Oil Fuel.

Where good oil fuel can be obtained at a moderate price, and with some degree of constancy, are questions which have often exercised the minds of those interested in the application of petroleum as fuel for warships. Tests have been made with Russian oil and with mineral oil from other sources, but as regards the oil obtained from Russia, it has been asserted that that country would have it in its power to cut off the supply if it thought fit. Canada now appears in the field with an oil which it claims is specially adapted for use as fuel. In the oil fields of West Ontario twenty-eight million gallons of crude petroleum are produced annually, and the oil is said to be of a heavier specific gravity than the United States' oil, and contains a larger percentage of carbon than either the Russian or American oil. Oil fuel, it appears, has been used in Canada for the last twenty-five years under ordinary steam boilers, and no difficulty whatever is experienced in applying this admirable system of heating by liquid fuel wherever it is desired to use it. The combustion is absolute and complete, there is no trace of smoke visible where this petroleum fuel is used, and the heat can be regulated and controlled with great ease and precision. The oil used is not the crude petroleum just as it is pumped from the rock, but a residuum which is obtained after the distillation of the water and lighter hydro-carbons from the crude, which are of little use as heat-giving elements. The partial failure of the trials on the *Surly* is probably due either to the quality of the oil used or the inferiority of the burner, but if the non-success is due to the first-named, the Canadian petroleum might be given a chance. It would be better all round if England could rely upon her supply of liquid fuel for her warships from her colonies instead of going to Russia or the United States for it. Oil that requires very little treatment, and is practically odourless, can also be obtained from Borneo.

Chatham Dockyard.

With the *Venerable* and *Cruiser* building, and the *Goliath* and *Irresistible* completing, in addition to several vessels undergoing

a refit, there is plenty of work at this yard for all hands. As regards the first-named battleship, it is probable that she will be launched about the end of July. The estimated cost of material and labour is £845,000 for this ship, but it is expected that this will fall short of the real amount required by some £20,000. While the Japanese cruiser *Tokiwa* was at this yard she had her launching gear removed, her under-water fittings completed, and her bottom covered with anti-fouling composition. The cost will, of course, be defrayed by the Government of Japan. We have refitted here the *Forte*, *Sanspareil*, *Astrea*, *Severn*, *Swordfish*, and *Dreadnought*, and work on the whole of these vessels continues to make good progress. The *Dreadnought* has been supplied with a new set of boilers, and a preliminary trial turned out quite successful. The boilers were constructed at this yard, and the speed obtained was a good deal over 13 knots, so that the engineering staff here is to be congratulated. She is to be passed into the A division of the Medway Reserve, and will probably be commissioned for service in the Reserve Squadron. The refit of the *Warspite*, which has just left for the Pacific Station, cost nearly £20,000. This includes a new armament of ten 6-in. quick-firers.

A Good Story.

The letters on the naval-engineer question which recently appeared in the *Morning Post* over the *nom de plume* of "Reform" have at last come to an end. This is not to be regretted, for their tone was much too violent to allow of any good resulting from their publication. One of the questions with which "Reform" dealt with, it will be remembered, was that of giving naval engineers the authority to punish their own staff, and in connection with this question rather a good story recently appeared in a contemporary. It appears that Admiral Sir Vesey Hamilton was one time first lieutenant of the frigate *Desperate*, commanded by Captain Dunning White. Captain White one day informed Lieutenant Hamilton that he intended to delegate to the chief engineer the authority to punish the stokers, with which the lieutenant did not agree. "You can't do it, sir," he said frankly. "You may retain the authority yourself, or you may delegate it to me, but the regulations won't allow you to delegate it to anyone else." The skipper, however, was determined to have his own way and said so, whereupon Lieutenant Hamilton declared that, if he were stripped in this way of part of his powers, he should decline to act as first lieutenant at all. "Then I'll do without you, sir!" was the skipper's prompt response, and do without his 'first luff" he did. From that day Lieutenant Hamilton took his place as one of the junior lieutenants, and meanwhile the captain carried out the duties of first lieutenant himself. This lasted through the summer. but when the winter came, and the ship was daily encased with ice, it was too much for the skipper, and he gave in. Sending for Lieutenant Hamilton he told him "carry on" again. "And the stokers, sir?" said Lieutenant Hamilton. "Oh, d—— the stokers; you can do what you like about them!" Admiral Sir Vesey Hamilton, says the writer of this story, is now reputed to be the only officer on the flag list who is in favour of naval engineers having the authority to punish their own staff, but the gallant old admiral writes to say that this is not the case, and that he is still of the same opinion as when he was a lieutenant.

The Trials of the "Amphitrite."

The series of steam trials to which the new first-class cruiser *Amphitrite* has been subjected came to an end two weeks ago. In the course of these trials those in charge of the machinery endeavoured to solve the question whether the steam first used in pumps and other auxiliary machinery could be subsequently used in the evaporators for making fresh water for the boilers. The experiment was a success. As regards the ordinary steam trials, everything went off as well as could be wished for. On her first 30 hours trial at one-fifth of the full power the *Amphitrite's* rate of fuel consumption was 1·54 lbs., with an I.H.P. of 3,751, which is considerably less than the coal consumption of the other vessels of the same class, with practically the same I.H.P. On the second trial the machinery worked splendidly throughout, although severe weather conditions were experienced. This trial, which lasted 30 hours, showed that the mean power was 13,695 I.H.P., the coal consumption being 1·48 lbs. per I.H.P. per hour. After this came the gun and circle trials, and then the full-power trials, on which the contract conditions were exceeded. The mean power for the eight hours was 18,229 I.H.P., the ship being at her full displacement; and as regards the coal consumption, it proved to be the lowest yet recorded for water-tube boilers. Messrs. Vickers, Sons & Maxim are to be congratulated on the results obtained.

Warship Building in the United Kingdom.

According to Lloyd's shipbuilding returns for the past quarter the total tonnage of warships now building in the United Kingdom amounts to 434,065 tons. Seventeen vessels representing 152,870 tons are under construction at the Government yards and 281,195 tons, representing sixty-nine vessels, are accounted for in the private yards. Three first-class battleships are building at Chatham, three at Devonport, three at Portsmouth, one at Barrow, one at Birkenhead, and one at Jarrow, and orders for three others have been obtained by the Thames Ironworks Co. At Barrow one first-class armoured cruiser is under construction, two at Clydebank, and two others at Govan, each of these vessels to displace 12,000 tons. One first-class cruiser, three second-class, and four third-class, in addition to four gunboats and six sloops, are also under construction in this country for the Navy. Five torpedo-boat destroyers are in hand at Clydebank, three at Chiswick, and three at Hebburn, and five others in different parts of the country. Thirty-one vessels are in hand for foreign Governments, of which there are on the stocks at Elswick six armoured vessels, three protected cruisers, and two torpedo-boat destroyers. The Thames Ironworks Co. are building a battleship for Japan, and Messrs. Yarrow are building four destroyers and five torpedo-boats for our "friends" the possible enemy.

Pembroke Dockyard.

At the present time, work on the new Royal yacht takes precedence of everything else. A week or so back Sir William White and Rear-Admiral Fullerton visited this yard, and spent a good deal of time on board the new vessel. Efforts are being made to have her as far advanced as possible when she is launched, for the Duke of York is to make an inspection of the ship on the day following this event. The Duke and Duchess of York are to arrive at New Milford on the 8th inst., but will sleep that night on board the present *Victoria and Albert*, prior to giving the name at present borne by this vessel to the new yacht. The copper sheathing of the new vessel is finished, and she received her first coat of paint some few weeks back. The carved work which is to be placed on the bows will be put up on the day of the launch, but afterwards removed. Roughly speaking, the estimated cost of the new yacht is to be £354,000, and not, as has been stated in some papers, "nearly a million." Although so much attention is being given to the new Royal yacht, the new armoured cruiser *Drake*, which is preparing to build here, is not forgotten. Most of her keel-plates have been prepared, and some of them temporarily connected together.

The British and French Squadrons in Italian Waters.

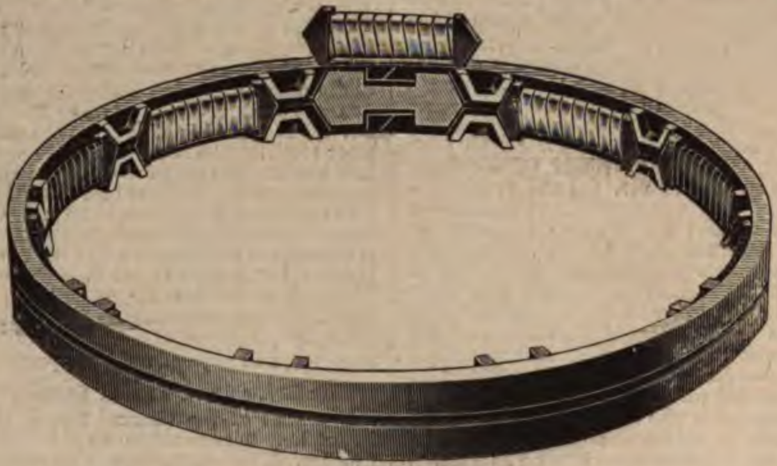
The visit of the Channel Squadron to Sardinia, will, it is hoped, help to cement the good feeling between Italy and this country. There appears to be no need for jealousy or mistrust on account of the kind reception given to the French Squadron, for it is to Italy's interest to do all in her power to keep open the Mediterranean, and therefore it would not pay her to listen to overtures made by the French. Admiral Fournier entertained the Italian officers on board the *Brennus*, and on this occasion said that he hoped to see a more rapid expansion of the Italian Navy. He is also reported as declaring himself much pleased at the reception given to the French Squadron, and expressing a hope that the reception would make an excellent impression in France by affirming once more the fraternity of the two countries which have so much interest in coming to an agreement. France and Italy are always likely to be in agreement if the latter country chooses to give way to the former's pretensions. The British Squadron arrived in the Gulf of Aranci on the 17th of April, and is to remain in Sardinian waters until the 2nd of this month, visiting during its stay the Gulf of Palmas, Cagliari Bay, Porto Conte, and the roadstead of Alghero. Altogether there were eighteen British warships, fifteen French, and fourteen Italian.

The Kaiser in a new Role.

From the news to hand it appears that William II. of Germany has taken upon himself the direct personal command of his navy, and a cabinet order has been issued having regard to the new organisation. The "Ober-Kommando der Marine," has been dispensed with, with the exception of one branch, which will be known as the "Admiralstab der Marine," with headquarters at Berlin. Prior to its being done away with, the "Ober-Kommando der Marine," controlled and directed the Baltic and North Sea stations, the squadrons, and the inspectorates of ordnance, torpedo matters, the marine infantry, and the training. Rear-Admiral Bendemann is to be the chief of the staff of the new Admiralstab Der Marine, and is to be directly responsible to the Emperor, who will, through the staff, direct the "politico-military affairs connected with ships on foreign stations." The chiefs of the two naval stations, the inspector of training, as well the commanders of the first squadron and cruising squadron are all to be immediately subject to the Emperor. The general result of these and other changes will be, too, to place the Emperor in practically the same relations with the fleet as he is with the Prussian army.

THE CLYDE PISTON RING.

WHEN high pressure steam gets behind the piston it presses it with considerable force against the cylinder walls and so causes much friction. Were it possible to prevent the ring from expanding beyond a certain amount it would be ensured that the pressure producing the friction would not exceed a certain amount. This the Clyde piston ring, sold by Messrs. John Turnbull, Junr. & Sons, of 39, Victoria Street, Westminster, London, and 18, Blythswood Square, Glasgow, provides for. It will be seen from the figure that the ring is kept from springing out too far by means of the holder with the enlarged ends. This fits into a place made for it, and being of H shape keeps the ends from going further than a definite distance out.



The packing itself is practically a plain ring kept tight between the piston head and junk ring with a ready means of adjusting lateral wear. The clip-lock ensures perfect steam tightness with minimum friction. The springs in the ring are interchangeable, except that fitted at the cuts of the ring. These openings in the ring are always kept in line in the same section, and not placed at right angles or opposite. The lock heads are reduced from time to time to adjust the wear and the expansion.

They have been fitted into the cylinders of engines in the Donaldson Line, Bell Line, and other lines.

Messrs. Echalaz & Leith, of Newcastle-on-Tyne, have been appointed sole agents in the North-East Coast district for the well-known Sheffield firm of steel manufacturers, Messrs. Thos. Firth & Co., Limited. In our announcement of this appointment in the April number the name of the first-mentioned firm was given incorrectly.

ELECTRICAL NOTES.

(From our own Correspondent.)

THE wireless telegraphy, which is so much to the fore in the ordinary newspaper at present, and as it is destined to be of moment to all who go down to the sea in ships, so the first message transmitted across the Channel will be of interest to all those who take a deep interest in this subject. That message was despatched to the *Times* on Tuesday, the 28th of March, and runs as follows:—"Communication between England and the Continent was set up yesterday morning by the Marconi system of wireless telegraphy. The points between which the experiments are being conducted are South Foreland and Wimereux, a village on the French coast two miles north of Boulogne, where a vertical standard wire, 150 ft. high, has been set up. The distance is 32 miles. The experiments are being carried on in the Morse code. Signor Marconi is here conducting the trials, and is very well satisfied with the results obtained."

This as a working system has been greatly successful, and it will be of still further interest to consider Signor Marconi's explanation of it. He first began with a distance of 1¾ miles, and noticed that a very small movement of the transmitting reflector was sufficient to stop the signals at the receiving end, which could only be obtained within a latitude of 50 ft. to the right or left of the centre of the beam of reflected radiations. The receiving apparatus is placed in the focal line of a reflector, and within range of the oscillator, and the bell will ring only when the reflector is directed toward the transmitter, and will not ring when the reflector is not directed towards it. If the reflector is caused to revolve by clockwork or by hand, it will therefore give warning only when occupying a certain sector of the circle in which it revolves. It is therefore easy, in the case of a ship in a fog, for it to make out the direction in which another ship may be signalling to it; and by the conventional number of taps or rings she will be able to discern either a dangerous point to be avoided, or the port or harbour for which she is endeavouring to steer. He succeeded in signalling over a distance of 2½ miles, and by means of reflectors he succeeded in signalling over 1¾ miles, mentioned by Mr. Preece at the meeting of the British Association of 1896.

In the beginning of last year a station was erected at Alum Bay, Isle of Wight, and another at Bournemouth, the distance between being 14½ miles, in order to test the practicability of the Marconi system under all conditions of weather. At Alum Bay the station was in the Needles Hotel, and in Bournemouth at Madeira House, South Cliff. At each station a pole 120 ft. high was used, which supported the aerial conductor, a stranded conductor of 7·20 copper wire insulated with rubber and tape. A 10-in. induction coil is used at each station worked by a battery of 100 Obach cells M size, the current taken by the coil being 14 volts from 6 to 9 amperes. The spark discharge takes place between two small spheres about 1 in. diameter, this form of transmitter having been found more simple and more effective than the Righi oscillator. The length of spark is about 1 centimetre. The experience was that no kind of weather can stop, or seriously interfere with the working of such an installation. In September of last year the station at Bournemouth was transferred to the Haven Hotel, Poole, making the distance eighteen miles. Better instruments allowed the height to be reduced to 80 ft. An average of 1,000 words were daily transmitted. In May of last year Lloyd's asked that stations should be placed at Ballycastle and Rathlin Island in the north of Ireland. The distance was 7½ miles, of which four were overland, and the remainder across the sea, a high cliff intervening. At Ballycastle a pole 100 ft. high was used to support the wire; at Rathlin the lighthouse supported a pole 80 ft. high. At Rathlin the lighthouse keepers soon learned how to work the wires, and the station was worked by them alone. In July the Dublin *Daily Express* asked that the results and incidents of the Kingston Regatta should be reported. A station in the grounds of the harbour master of Kingston was made, and a pole 110 ft. high placed. A steamer, the *Flying Huntress*, followed the yachts. The height of the vertical wire on the mast was 75 ft. A telephone was fixed at the station on land and connected with the *Express* office, and the messages sent in as they came were published in succeeding editions of the paper. Over 700 messages were sent and received. With a height of 80 ft. on the ship communications could be made at a distance of 25 miles. The curvature of the earth interfered at long distances. Three stations were installed at Cowes. The height of the pole at Osborne House was 100 ft., and the conductor was suspended to the top of the mast of the royal yacht *Osborne*, the height of which was 83 ft. from the deck. The vertical conductor consisted of a 7·20 stranded wire at each station. The distance was 1¾ miles, the hills of East Cowes were between the two stations, and the one could not be seen from the other. Uninterrupted communication was maintained between the royal yacht and Osborne House during the sixteen days the system was in use. Here is one of the messages:—

"From Dr. Fripp to Sir James Reid.

"H.R.H. the Prince of Wales has passed another excellent night, and is in very good spirits and health. His knee is most satisfactory."

Electro-plating the Hulls of Vessels.—The tug *Assistance*, an ocean-going boat, was electro-plated and launched on Feb. 22nd, 1895, and a short time ago, when hauled out of the water and examined, she was found to be absolutely free from barnacles. For the last year she has been touring in the lower waters of the Chesapeake, and remained constantly at work while other tug boats had to be taken out every four weeks. The method consisted in the use of flexible shallow box-shaped baths open at one side, each bath containing a copper electrode and the plating solution, the bath being made water-tight by flexible packing at the edges. The baths are made to follow the curvature of the vessel by means of tension ropes, screw stems, or by magnets attached to the frame of the bath. The vessel is made the negative pole by connection with an electric generator, the plating bath is the positive electrode; and the plating of the hull is accomplished by shifting the baths from the plated to the unplated sections, and slightly overlapping upon the sections already placed so as to form a continuous coating. A current of 7½ amperes per square foot and a difference of potential of 1¼ volts are sufficient to deposit a uniform coating on the surface of the vessel. To keep the density of the solution uniform, circulation is effected by permitting the solution to flow into the bottom and out near the top of the bath. A single deposit can be made in less than three days, and the whole bottom of the ship can be plated in eight or nine days.

150-ton American Electric Crane.—The Newport new shipbuilding dry dock in Virginia has fitted in it a 150-ton revolving derrick electrically operated, mounted on a steel tower supported on pile foundations. The derrick jib is capable of having its outer end raised or lowered, thus giving to the hoisting blocks which depend from this end a movement of rotation about the centre of the derrick, but also of translation in or out of the centre. With the outer end of the jib in its lowest position the hoisting blocks will in rotation of the derrick describe the circumference of a circle 207 ft. diameter; with the jib in its highest position these blocks in rotation describe the circumference of another concentric circle 88 ft. in diameter. Weights up to 70 tons may be handled throughout the entire range. The derrick, says *Electrician*, is revolved by duplicate sets of machinery, each consisting of one G.E. 800 railway motor capable of developing 20 H.P., and driving, by means of a double threaded worm and wheel, a pinion which, engaging a horizontal circular rack on the outside of the tower, gives the required rotation. The racking movement of the jib is effected by a 10 in. steel pin carrying 22 cast steel sheaves, each sheave of 5 ft. pitch diameter at the inner and upper apex of the jib, and at the upper apex of the housing is another 10 in. steel pin carrying 24 sheaves. Two 1¼ in. steel ropes carry the weight of the jib and load by leading over the sheaves, each rope being bound in alternate sheaves, and each end of each rope brought down to separate drums located below in the housing, and by this means each rope is caused to take its share of the weight. The four drums on which these ropes are wound are arranged in pairs, each one of a pair taking opposite ends of the same rope, and each pair driven by a G.E. 2,000 series motor of 100 H.P. The drums are of cast iron 5 ft pitch, and carried in 7 in. steel shafts. The main hoists are each 12 parts 1½ in. steel wire rope leading over six sheaves, 5 ft. pitch diameter, carried in a 10 in. steel pin at the outer end of the jib. The hoists may be coupled together and operated as one hoist of 150 tons.

UNITED STATES METALLIC PACKING CO., LIMITED.

THE United States Metallic Packing Co., Limited, of the Soho Works, Thornton Road, Bradford, Yorkshire, who have been manufacturers of metallic packing for the last 25 years, have found that they have supplied in this time over 105,000 metallic packings for use in engines all over the world.

The packing, as is well known, consists of blocks faced with anti-friction metal, which are held in strong rings, having pockets or horns containing springs. The blocks are placed in pairs above one another so as to break joint. A ball joint supports the packing on one side and a spring-pressed follower on the other, so that the packing is practically floating, and keeps steam-tight without regard to the vibration of the rod. As the friction between the rod and packing is very small, the rod is practically not worn appreciably, but only receives a high polish.

With efficient lubrication the blocks wear very slowly, and we understand that many of this company's packings have given 16 years' service without renewal of blocks, which, of course, are the only parts of the packing liable to wear. In the construction of this packing special attention appears to be paid to the reduction of clearance space to the minimum, no empty space being allowed beyond that necessary to permit the vibration of the rod. Special provision is also provided to reduce condensation as far as possible. Drain valves are usually provided to permit the removal of water, core, sand, and other accumulations. Special attention has also been given to its use with superheated steam, and it gives excellent results, working at a temperature of 700°Fahr.

This packing has been fitted to the machinery of H.M.S. *Terrible*, *Ariadne*, *Niobe*, *Diadem*, *Argonaut*, *Europa*, and *Jupiter*, having an aggregate of over 120,000 I.H.P., and also to 20 other vessels of H.M.'s Navy. Then 28 ships of foreign navies have been fitted, also the steamers of the following well-known lines: American Line, City Line, Donald Currie & Co., Head Line, Union Line, Red Star Line, and most of the railway companies who have steamers of their own.

Among the very extensive stock of testimonials that have been received by the company from their customers we notice there are many people who testify to having used the packing for over 10 years without

costing them a penny in repairs, while others find they are saving from £8 to £10 per annum in packing renewal alone, an advantage which is quite apart from greater efficiency of working obtained by the use of the packing.

MARINE ENGINEERS' NOTES.

(From our own Correspondent.)

THE annual meeting of the Institute has taken place, and the report shows a very considerable improvement and a steady advance. The increase of membership was 78; deaths were 13; resignations, 11; and removals, 2. The membership now stands at 1,035; the increase in the membership was thus 78, as against 55 for the previous session. The honorary secretary also specially mentions the gifts of experimental apparatus by Mr. J. H. Hallett (member), and of the promise of another apparatus by the editor of the ENGINEER; and he further informs the members that they were suggested as a result of the discussions held on water-tube boilers, coal combustion, and feed-water heaters. Both apparatus have been in working, and some good results have already been obtained from it. These will probably be given as a paper before the Institute. In pursuing these investigations the council of the Institute have given every encouragement, both by freely allowing their premises to be utilised for the purpose and by making a grant of money and placing it at the disposal of this work as it may be required. But the council have not stopped at doing this good work in their collective capacity. They have taken an interest in it individually. Some of the associate members are at present making drawings, and they will construct from them models and apparatus for experiments in the laboratory. Mr. Sage has kindly offered to provide all the brass castings for this apparatus, and Mr. Boyle has offered to supply the timbers required. Other members of council have undertaken to make some parts of the apparatus altogether. All that is now required is that the younger members should volunteer to construct the apparatus required. The models are also to be increased as soon as friends of the Institute can be got at to make them and send them in. Messrs. John Turnbull & Sons are sending in a patent Clyde piston ring and a tapered mandrel, and Mr. Whitelegg, the assistant superintendent of the London, Tilbury, and Southend Railway, is to present the Institute with a photograph of a locomotive of the London and Tilbury line. The laboratory will always be open for members to work in on Friday evenings.

The Exhibition which is to be held in Paris in 1900 will have a department relating more closely to technical science, and a committee in Paris has invited the council of the Institute to co-operate with them to arrange a conference to discuss subjects interesting to the members.

Mr. Shorey, in making his annual statement as treasurer, said that with a membership of 1,035 they had spent less than with a membership of 983. The expenditure of the former session was £974, against £914 this, which showed a saving of about £60. The recreation section showed a loss of £2, against a profit of £14 last year. Mr. Boyle, in moving a vote of thanks to the retiring president, Dr. Inglis, said, as marine engineers, they ought to be very proud indeed that their presidents "have been gentlemen who stand in the front rank of their profession, whether as scientists as Lord Kelvin, naval architects like Sir Wm. White, or consulting and superintending engineers with great responsibilities attached to their positions. Then we have had those great potentates in the shipping and commercial world like Sir Thos. Sutherland and Sir Edwyn Dawes, and engineers and shipbuilders combined like Dr. Peter Denny and Dr. Inglis. In Dr. Inglis we have one who served an apprenticeship himself, and has been in close touch with marine engineers ever since." The motion was seconded by Mr. R. Adam. Dr. Inglis wrote as follows:—"Dear Mr. Adamson,—I duly received your favour of the 27th inst. intimating the Institute's vote of thanks to me as retiring president. It has been a source of great regret to me that I have been prevented attending the ordinary meetings during the session now closed; but, as you know, I have not been in my usual state of health of late, and since August last have not been in London except at the time of the annual dinner and again in January. I have to thank Mr. Boyle for his remarks at the annual business meeting, and to express my gratitude also to yourself, to Mr. Taylor, and all the members of council for making my duties so light and agreeable.—With warmest wishes for the continued prosperity of the Institute of Marine Engineers, I am, yours faithfully, John Inglis."

Mr. A. Brown (companion) proposed a vote of thanks to the office-bearers and members of council of the Institution. Mr. W. Lawrie (member), in seconding the motion, said "that the Institute is going on and flourishing, there cannot be the least doubt, and that is mainly due to the office-bearers and council who conduct our business. Their work goes on during the whole year." Mr. James Adamson (hon. secretary) thanked the members for their vote of thanks. He referred also to the attendance at their meetings on Mondays. It was proposed that the legacy left by the late Mr. Stephens be devoted to a silver medal. The scrutineers then presented the result of the voting as follows: President, Sir James Mackay: hon. treasurer Mr. F. W. Shorey; hon. secretary, Mr. James Adamson; members of council: Mr. A. Boyle, Mr. W. L. Taylor, Mr. A. G. Crighton, Mr. A. Campbell, Mr. A. Blair, Mr. J. Blelloch, Mr. J. W. Richardson, and Mr. C. G. Newby (hon. minute secretary). Bristol Channel centre: President, Sir John Gunn; vice-presidents, Mr. M. W. Aisbitt, Mr. J. W. Wailes, and Mr. J. F. Walliker; representative to council, Mr. T. A. Reed; hon treasurer, Mr. A. E. Smithson; hon. secretary, Mr. Geo. Sloggett. Members of committee: Messrs. J. Fleming, W. Scott, D. Gibson, R. Williamson, J. Chellew, G. Rutherford, J. Boddy, and W. Simpson.

The following have been presented to the Institute during the session: Sectional model of steam engine fitted with Joy's valve gear, Jas. Stark, member; photo. Argentine cruiser, *Buenos Aires*, H. Bertram; framed photo. of the late J. H. Thomson, Mrs. Thomson; framed photo. s.s. *Milwaukee*, John Ferguson. member.

The Institute has had under notice the proofs of Scott's Code. It is in its sixth edition, and that is sufficient to show the service it has been to very many shipowners and others who would require to pay a large sum to send a message by cable home. It has been divided up by the compilers into sections under headings, and arranged alphabetically. The code is formed on the same system a the codes of engineering firms are arranged for their machines. "Will be ready in a month" is represented by one word. The first page will give an idea of the manner in which the book is made. Section 1, general; section 2, rig; section 3, tonnage; section 4, dimensions. "Is she a steamer or sailing vessel?" is represented by Fumigating. All the other questions and answers under "General" are represented by words beginning with F. The book is octavo, and is about 2 in. thick.

The Institute was again engaged considering the new rules and changes of rules for the examination of engineers for Board of Trade certificates. It was in consequence of the Institute making representations on the question that the Board of Trade requested the Institute to express an opinion on them before they were finally drafted and adopted.

Mr. Hawthorn, who was in the chair, said the effect of the rules would be generally in the direction of stiffening the examinations for engineers' certificates, and the effect of that was to raise the status of engineers. Under rule 22 there were four sub-sections which were entirely new. They were as follow—"He must be able to apply the method of testing and altering the setting of the slide valves, and method of testing the fairness of shafts and adjusting them. He must be able to calculate the suitable working pressure for a steam boiler of given dimensions and the stress per square inch on crank and tunnel shafts, when the necessary data are furnished. He must understand the construction of steering engines evaporators, feed filters, and feed heaters. He must understand the construction of centrifugal bucket and plunger pumps, and the principle on which they act." Again, under rule 23. The old rule was—a candidate for a first-class certificate had to serve as second, third, or fourth engineer in a foreign-going ship, or as second engineer in a home-trade passenger steamer. Under the new rule he had to serve as senior engineer in charge of a watch on a foreign-going steamer, or as first or second engineer of a home-trade steamer; but the vessels must at least be 99 N.H.P., and he must understand the construction of, and be able to maintain in working condition, the auxiliary machinery which is placed under his charge, viz, refrigerating machinery, electric light engines and dynamos, electric motors fitted to ship's boats, hydraulic machinery, and the various descriptions of steering gear. For extra chief certificates: "He must be able to explain the construction and working of the refrigerating machinery in use on board ship, the electric lighting plant, the steering engines, hydraulic and pneumatic engines, the pumps, and all other auxiliary machinery placed under the chief engineer's control. In order to intelligently deal with ballast tanks—the cocks, valves, and pumps of which are under the chief engineer's control—and to co-operate the more readily with the master in keeping the vessel in a safe condition, especially when she is light, and when coaling operations are proceeding, candidates are expected to possess an elementary knowledge of the stability of floating bodies."

Strong objection was expressed by several members to rule 42, which is as follows:—"An officer who has attained the rank of engineer or assistant engineer in her Majesty's Navy or Indian Marine Service is entitled without examination, if an engineer, to a certificate of service as a first-class engineer; and if an assistant engineer, to a certificate of service as second-class engineer. These officers may be examined for a certificate of competency on the same conditions as engineers of the mercantile marine."

Mr. Halliday moved that it be strongly recommended to the Board of Trade that a naval engineer should only be allowed to apply for a certificate under precisely the same conditions as an engineer in the mercantile marine.

Mr. F. Cooper seconded the motion, and it was supported by Mr. Lawrie, Mr. Mather, and others, and carried *nem. con.*

R.M.S. "ARCTURUS."

THE Finska Angfartyg's Aktiebolaget's (Finnish Steamship Co.'s) newest Royal Mail steamers *Arcturus* and *Polaris* have been built for carrying on the passenger and goods' trade between Finland and England.

In summer these steamboats run between Hull, Hango, Abo, or Helsingfors, but in winter only to Hango. They are specially built for the winter trade, and there seems now very little fear of Hango ever again being closed, as these two steamers, together with the new powerful Finnish ice-breaker, the *Sampo*, are capable of making a passage through ice of almost any thickness.

One of the two steamers leaves Hull and Finland every Saturday, being due at their destination, after a short call at Copenhagen, the following Wednesday. The agents in Hull are Messrs. John Good & Sons.

Both vessels were built and engined by Messrs. Gourlay Bros. & Co., of Dundee, and are elegantly fitted up.

We give a double-page plate of four views taken on board the s.s. *Arcturus*.

She is 294 ft. long by 38 ft. broad and 21 ft. displacement, and 1,157 registered tonnage. Her engines are triple-expansion of 4,000 H.P., driving 15 knots per hour. She has accommodation for 72 first-class passengers, 38 second, 179 emigrants, and 22 home-returning sailors.

The first-class berths, elegantly and suitably furnished, are situated amidships, as is also the particularly tastefully fitted-up dining saloon, in which more than 60 passengers can be seated at table. The saloon, besides having the several usual port-holes, has a large beautifully-painted domed skylight. Connected with the saloon is the serving-room, which is unusually capacious, and which has a lift to the kitchen, and is connected with the smoke-room by telephone. The smoke-room is on the bridge deck, and has a mosaic floor and walls decorated with exquisite carvings representing Scottish subjects—as the Forth and Tay Bridges, Piper Findlater, &c., &c. The furniture is both elegant and durable. On the same bridge deck as the smoke-room are also situated the captain's and chart-rooms. One enters through the latter into the captain's ante or workroom, to which is connected his bedroom. On the same level is the commanding bridge, which is fitted with an electric search-light, and has telegraphs and speaking tubes to the captain's, steam-steering apparatus, and engine-rooms. Yet one floor higher is built a smaller commanding bridge, from which high standpoint the captain can have a splendid view of his vessel from fore to aft.

The second-class berths are aft, and are roomy, comfortable, and splendidly furnished. From the second-class saloon a broad staircase leads up to the second-class smoke-room, which is on deck. Both the first and second-class berths are fitted with every convenience, and have lavatories and toilet-rooms. There is a splendid first-class bath-room, with fresh or salt water. On the top of the staircase leading from the first-class berths to the saloon is a daintily-furnished ladies' room. Electric light and hot-water pipes are fitted throughout, and everything speaks of comfort and luxury.

The emigrant quarters are forward—the men's at one side of the vessel and the women's at the other. They have their separate kitchen, pantry, and toilet-rooms. They have their meals served between decks. Further forward are the crews' berths, the crew consisting of 44 persons, including the stewardesses, cooks, and 14 men in the engine-room.

On one side of the corridor which runs between decks, between fore and aft, are the officers' berths and mess-room.

The steamer has three large holds and powerful cranes and winches.

Hartmann's Rahtjen's Improved Composition.—We have received from Messrs. Suter Hartmann & Rahtjen's Composiinto Co., Limited, a list of some of the vessels coated during the recent three months with the above improved composition for ships' bottoms. This list copmrises vessels of every type and class, including numerous war vessels belonging to the British and other Governments, large mail steamers, and passenger and cargo vessels trading to all parts, representing a total tonnage of no less than 1,777,928 tons, and in addition the composition has also been applied to a large amount of tonnage in various parts of the world, returns of which have not yet reached the head office. Hartmann's grey anti-corrosive paint has also been applied to a great number of vessels for inside protective purposes, such not being included in the above tonnage.

Catalogue.—The Southgate Engineering Co., of New Southgate, send us a new and very practical Catalogue of their patent Steam Pile Driving Appliances. The work is written in three languages—English, French, and German. It is well illustrated and commences with a lucid explanation of the peculiarity of the firm's device for obviating the defects which usually attend the use of flexible pipes with steam monkeys. They give a selection of the testimonials they have received from customers who have been pleased with the work their machinery has effected and with its economical results. They give data as to the amount of work which can be effected by their use. For example, at the Clacton-on-Sea defence works a 20-cwt. steam pile driver of this type has driven no less than 183 piles 12 in. by 6 in. a distance of ten feet into the ground in a working week. This is stated to be a record. At the same time the life of the flexible piping was unusually prolonged. The cost of the pile drivers of various weights is set out into the catalogue together with the code word of each, so that important orders may conveniently be transmitted by telegraph without danger of error or confusion.

NAVAL ENGINEER APPOINTMENTS.

The following appointments have been made at the Admiralty from March 25th to April 24th, 1899 :—

Anderson, A. R., engineer to the *Tamar*, for the *Handy*, to date April 18th.
Apps, W. R., chief engineer to the *Forte*, to date April 20th.
Archard, A. G., assistant engineer to the *Trafalgar*, to date March 23rd.
Ash, H. E. H., engineer to the *Pembroke*, for the *Cynthia*, to date March 28th.
Ash, H. G., assistant engineer to the *Pembroke*, additional, for the *Tribune*, for recommissioning, to date March 30th.
Backler, L., engineer, has been promoted to the rank of chief engineer in her Majesty's fleet.
Baker, E. F., assistant engineer to the *Magdala*, to date March 29th.
Begg, W. (probationary), assistant engineer to the *Pembroke*, to date March 23rd, and to the *Forte*, to date April 20th.
Bell, J. F. (probationary), assistant engineer to the *Crescent*, to date May 2nd.
Broadbent, C., engineer to the *Pembroke*, for the *Lee*, to date April 7th.
Brown, P. R. T., engineer to the *Diadem*.
Brown, T. F., assistant engineer to the *Pembroke*, to date March 23rd, and to the *Forte*, to date April 20th.
Cox, A. E., chief engineer to the *Pembroke*, for the *Skipjack*, to date March 25th.
Cox, H. B. T., engineer to the *Duke of Wellington*, for the *Dove*, to date April 12th.
Croisdale, L. R., assistant engineer to the *Royal Sovereign*, undated.
Dathan, W. A., engineer to the *Duke of Wellington*, for the *Bullfinch*, to date April 12th.
Davies, R. B. (probationary), assistant engineer to the *Pembroke*, additional, for the *Tribune*, for recommissioning, to date March 30th.
Dawson, F. G., engineer to the *Vivid*, for the *Shark*, to date March 17th.
Evans, A., assistant engineer to the *Vivid*, for the *Psyche*, and for recommissioning, to date March 29th.
Freeman, B. F. (probationary), assistant engineer to the *Royal Sovereign*, for recommissioning, to date April 19th.
Garde, R. B., engineer to the *Vivid*, for the *Skate*, to date March 18th.
Gavey, A., assistant engineer to the *Royal Sovereign*, for recommissioning, to date April 19th.
Graham, W. J., chief engineer to the *Pembroke*, additional, for the *Mersey*, to date April 12th.
Hall, F. M., assistant engineer to the *Colossus*, to date March 23rd.
Ham, J. W., engineer, has been promoted to the rank of chief engineer in her Majesty's fleet.
Ham, J. W., chief engineer to the *Barfleur*, for the *Fame*, to date March 4th.
Hardcastle, C. V., engineer to the *Duke of Wellington*, supernumerary, to date April 4th.
Haves, J. E., engineer to the *Goldfinch*, to date April 7th.
Hill, C. H., engineer to the *Duke of Wellington*, for the *Viper*, undated.
Jacobs, F. G., chief engineer to the *Melampus*, for the *Gossamer*, to date April 7th.
Jones, G. W., assistant engineer (temporary), to the *Australia*, to date April 4th.
Juniper, W. V., chief engineer to the *Pomone*, to date May 18th.
Lawrence, W. G., engineer to the *Widgeon*, to date April 4th.
Ludlow, G. T. J., chief engineer to the *Duke of Wellington*, for the *Cordelia*, to date April 11th.
Ludlow, G. T. J., chief engineer to the *Duke of Wellington*, for the *Naiad*, to date April 27th.
Massey, J. S., assistant engineer to the *Duke of Wellington*, for the *St. George*, to date April 12th.
McGregor, D. J., assistant engineer to the *Pomone*, to date May 18th.
Mew, W. H. (probationary), assistant engineer to the *Renown*, to date March 27th.
Mew, W. H. (probationary), assistant engineer to the *Crescent*, to date May 2nd.
Milton, W., staff engineer to the *Pembroke*, for the *Ariadne*, to date April 22nd.
Morgan, T. J., acting engineer to the *Galatea*, to date April 19th.
Morison, R. B., engineer to the *Duke of Wellington*, for the *Europa*, undated.
Noll, G. W., chief engineer to the *Tribune*, to date May 9th.
Page, F. J., engineer to the *Pembroke*, for the *Snapper*, to date March 15th.
Pratt, W. H., engineer to the *Duke of Wellington*, for the *Crescent*, and for recommissioning.
Rampling, H. J., fleet engineer to the *Vivid*, for the *Albion*, to date April 7th.
Rawling, S., staff engineer to the *Pembroke*, as overseer at Fairfield Works, and Wilson & Co., and Clyde District, to date April 27th.
Rees, J. D., chief engineer to the *Isis*, to date April 19th.
Rider, R. T., assistant engineer to the *Terrible*, to date April 12th.
Riley, W. H., fleet engineer to the *President*, for service at the Admiralty.
Ryan, J., chief engineer to the *Vivid*, for the *Phœbe*, to date April 12th.
Sanderson, P. A., assistant engineer (temporary), to the *Colossus*, to date April 19th.
Smith, J. A., inspector of machinery, to the *Niobe*, additional, temporary, to date April 27th.
Spencer, A.P.S., assistant engineer to the *Wallaroo*, to date April 7th.
Steil, W. J., assistant engineer to the *Crescent*, to date May 2nd.
Stuart, M., chief engineer to the *Psyche*, to date May 2nd.
Sydenham, E. D., assistant engineer to the *Royal Sovereign*, undated.
Teed, H. R., engineer to the *Pembroke*, for the *Mallard*, to date March 15th.
Toman, R. W., chief engineer to the *Vivid*, for the *Thames*, to date April 19th.
Watts, J. A., assistant engineer to the *Royal Sovereign*, undated.
Webb, A. T., acting chief engineer to the *Vivid*, for the *Charybdis*, to date April 7th.
Wishart, W. L., fleet engineer to the *Warspite*, to date April 7th.

INDUSTRIAL AND TRADE NOTES.

THE CLYDE AND SCOTLAND.

(From our own Correspondent.)

THE industrial record for April is virtually a repetition of that for March and February in respect of work accomplished and contracts entered into. There has been continued activity in the one case and even more accentuated stoppage than ever in the other. The output of new shipping reaches more than an average figure, while the contracts booked are few indeed, and mostly unimportant. This is doubtless an inevitable and quite legitimate—and acceptable—outcome of the abnormal condition of things which has obtained in shipbuilding and cognate industries for some considerable time now. The cessation of new orders will enable things to be brought back to something like their normal balance.

But, large as the output continues to be, it does not represent anything like the maximum possible and desirable, considering the present state of the employers' books and the orders which would be forthcoming if only greater celerity still were observed in launching and completing vessels on hand. Two influences which are notoriously at work in retarding progress are the slow and uncertain delivery of material—the delay and bother in some firms, experience being most vexatious—and the annoying waste of working time by certain branches of operatives. To a certain extent the former source of annoyance is responsible for the latter, but for most part, the loss of time by boilermakers and iron shipbuilders—the riveting sections especially—is attributable to unsteadiness, thriftlessness, and a lack of will or desire to make the very most of the present spell of good trade. For wilful and unauthorised stoppages of work on the part of members of the Boilermakers' and Iron Shipbuilders' Society, Mr. Knight, the secretary, has been soundly rating culprits in his recent reports, and certain of the Clyde employers have been publicly calling attention to the great cause they have for complaint in these connections.

Speaking at a social function in Dumbarton lately Mr. John Ward, managing partner of Messrs. William Denny & Brothers, said that at present among a good many of the workmen there was more unsteadiness than there had been in his experience of twenty-seven years. He had had special reasons for looking into this matter, because his firm had been trying to work against promised deliveries. He had taken during the last twelve months a close and keen oversight of the attendance of their men. Instead of resuming their work that day—the Tuesday following the Dumbarton spring holiday—a great proportion of the iron workers in their employ had not returned to work, and the chances were that the following day would still find them in the streets, spending both their time and money. All the heads of squads had that morning turned out, but the work could not be gone on with through the want of men. It meant a loss of about £400 worth of wages that would have been earned that day in the iron department, and the deliveries to that extent were thrown back.

This is not by any means a new trouble on the Clyde, but it has all along been noticeable that the greater the boom in the trade there has been a corresponding amount of unsteadiness and thriftlessness. Some twenty years ago when the wages of platers, frame setters, and riveters were exceptionally high, it was not uncommon for fully one-half of the "black squad" in each yard to be absent for the first two days at the beginning of a week following the pay. At the present time builders have much the same kind and degree of grievance to contend with. The workmen feel persuaded there is abundance of work for a couple of years to come, and while they can make a sufficiently adequate pay in, say, eight or nine days out of the twelve, they are unconcerned about getting the work out to contract time, unconcerned about the loss to the employer who keeps his machinery going and has besides a regulation staff to pay fixed wages. Allowing for time lost through bad weather, it has been computed that from 25 to 33 per cent. of time is lost on an average throughout the yards of the Clyde through unsteadiness of riveters and platers. The loss of time by engineers and brass finishers, it is gratifying to find, is comparatively small, and has been computed at from 5 to 10 per cent.

How far the adoption of weekly instead of fortnightly pays will help to promote greater steadiness and regularity at work is doubtful, but the feeling on the part of many of the shipyard managers and foremen is that more frequent payments will diminish the temptation to the usual "fortnightly burst," as at present obtaining with the black squad when flush of cash. It may also in other ways conduce to better working conditions. In any case the system is being introduced this month at the request of the men all over the river, and at considerably increased outlay to the employers, extra clerks having had to be engaged, and altered systems of time and book-keeping introduced.

The Fairfield Co.'s second-class cruiser *Hermes* has left the builders' dock, and after running her preliminary trials on the Firth will proceed to Devonport Dockyard to prepare for Admiralty trials. Her sister ship the *Highflyer* will follow in a week or so, and about the same time the 30-knot destroyer *Leven* will also leave for Devonport. Work is proceeding apace on the second-class cruisers *Cressy* and *Aboukir*, and a start has been made on the two additional destroyers recently ordered, as well as on the magnificent 23-knot armoured cruiser ordered about the beginning of the year.

The two splendid mail steamers for the Castle Packet Line building at Fairfield—to be called *Kinfauns Castle* and *Kildonan Castle*—have now reached the launching stage, and they will be sent off the stocks, the former early this month and the latter some time in June. These sister vessels are to be propelled by twin-screws—the first of the Castle packets so propelled—and are to be faster than any vessels now on the Cape route.

Messrs. Ritchie, Graham & Milne, of Park Shipyard, Whiteinch, continue to be fully employed with the construction of light-draught steamers and barges for inland lake and river navigation in various parts of the world, most of their productions being shipped in pieces and reconstructed at their destination. The following are some of their recent contracts:—Two paddle steamers 260 ft. long, 45 ft. beam, and 11 ft. depth, moulded, to be fitted with three lines of rails and six large turntables, enabling them to carry trains over the River Hooghly, India; four stern-wheel steamers of similar size and design, two of which are for East African river service, one for the Congo, and the fourth for the River Plate.

Messrs. Napier & Miller, Limited, the new firm who have now started operations in the shipyard at Yoker, formerly occupied by Messrs. Napier, Shanks & Bell, are already well provided with work, several of the contracts being for large cargo-carrying steamers. Two of these are vessels of 400 ft. keel, and of about 7,000 tons deadweight capacity, ordered by Messrs. Robert Mackill & Co., Waterloo Street, Glasgow, and a third of almost similar size is for another firm of Glasgow owners. Messrs. Napier & Miller, not being themselves engineers, are sub-contracting with engineering firms in Glasgow for the supply of the necessary engines and boilers for these vessels. Other work in hand by the Yoker firm are twelve cargo barges, each of about 150 tons capacity.

Messrs. Fleming & Ferguson, engineers and shipbuilders, Phœnix Works, Paisley, have received an order from the Admiralty for two lightships, one of which is intended for service at Sheerness and the other at the Cape. All departments of Messrs. Fleming & Ferguson's works are at present fully occupied.

Both Messrs. William Simons & Co., and Messrs. Lobnitz & Co., at Renfrew, are as usual busy with their own specialities in the way of dredgers and hopper barges, &c. Messrs. Simons & Co. have three dredgers in hand and three steam hopper barges, all for foreign owners. Four of the vessels are in an advanced stage of construction, the other two not being quite as well advanced. The firm have orders on the books to take the place of vessels that may be launched. In December last the firm launched the powerful dredger *Alexander Golovatcheff* for the Russian Government, but during heavy weather, when barely clear of the Channel on her way to Odessa, her main shaft broke and she had to be abandoned, her crew being taken off by the White Star Line steamer *Tauric*. On March 28th last another dredger of similar design was launched by Messrs. Simons, also for the Russian Government, and she has been given the same name. She went through severe trials about two weeks ago in the harbour of Greenock and on the bank near Craigendoran, when, it is understood, she dredged or lifted no less than 360 tons in 18 minutes.

The Clydebank Engineering and Shipbuilding Co. have begun to lay down on the berth vacated by the Japanese battleship *Asahi*, not the keel of the 23-knot armoured cruiser *Leviathan*, as wrongly reported, but that of one of the large Atlantic liners they have on hand for the International Navigation Co., of New York. It has for some time been rumoured that the Clydebank Co. bave been commissioned to build not two only, but the whole four steamers the International Co. are adding to their fleet, two of which it was the original intention to place with American builders. It now appears quite certain that the whole four vessels have been entrusted to the Clydebank Co. An official of the owning company has recently stated that the company has been unable to find a shipyard in the States in a position to undertake the building and delivery of the steamers within a time suitable for the service, all the yards being so busily engaged. It is understood, however, that a large proportion of the material of which the vessels will be built is being sent from American steel works to the Clyde. This is so, at least, with respect to the two steamers first placed with the Clydebank Co. The rudders and sternposts are being made and despatched from the works of the Pennsylvania Steel Casting Co., of Chester, Pennsylvania, each of the rudders being one solid casting.

Messrs. William Denny & Brothers, Dumbarton, extensive though their premises be, are finding it more and more necessary to utilise surplus ground belonging to them lying outside their yard wall, but quite convenient and handy to the lower yard gate. On this ground they have already built many of the light-draught barges and other craft for which the firm is noted, and they are now proceeding to erect, and equip with the necessary plant, a large fitting shed, 150 ft. long by 50 ft. broad, alongside the ground in question. This step of Messrs. Denny's may be regarded as one more of many other indications, to be noticed on the Clyde, that the development of already established, and the opening up of fresh fields of commercial enterprise, by means of inland lake and river navigation, in various parts of the globe, are matters more and more on the increase, thus entailing on our home builders—of light-draught craft especially—extra energy and enterprise in meeting the demand.

Messrs. Blackwood & Gordon, engineers and shipbuilders, Port-Glasgow, whose patent slip has lately been greatly requisitioned for the cleaning and overhaul of Clyde passenger paddle steamers, launched about mid-month the steel screw steamer *Cork* for the City of Dublin Steam Packet Co., of Dublin. The new vessel, which is 260 ft. in length by 34 ft. beam and 16 ft. 9 in. moulded depth, is to be employed in the cross-channel trade between Dublin and Liverpool as consort to the four popular steamers *Louth*, *Wicklow*, *Carlow*, and *Kerry*, which steamers were also built by the firm. The machinery, which has also been constructed by Messrs. Blackwood & Gordon, consists of triple-expansion engines of fully 3,000 H.P., and two large double-ended boilers working up to 170 lbs. pressure. The *Cork* is built on similar lines to the former steamers, but with the improvement that she has accommodation for 50 additional first-class passengers, placed in private cabins amidships. During construction she has been under the supervision of Mr. Edwin C. Ferber, the company's engineering superintendent.

Messrs. David J. Dunlop & Co., of Inch Works, Port-Glasgow, have received an order to build and engine two large steel-screw steamers for the Woermann Line, of Hamburg.

Messrs. Drysdale & Co., of Bon-Accord Engine Works, London Road, Glasgow, whose specialities in the way of centrifugal pumps are so well known, and who, as a firm, celebrated their semi-jubilee in March last, are at present completing an installation of their pumps for the working of the new graving dock shortly to be opened at Troon. Other important contracts in hand and nearing completion are a large installation at the Prince of Wales New Graving Dock, Swansea, and an installation of four compound centrifugal pumping engines for the Wakefield Sewage Works.

At the sixth general meeting of the forty-second session of the Institution of Engineers and Shipbuilders in Scotland, held in the Institution Rooms, Bath Street, Glasgow, on the 21st April, Mr. George H. Baxter, mechanical engineer to the Clyde Navigation Trust, read a paper dealing with the pumping arrangements and various contingent mechanical details connected with the Clyde Trustees' new graving dock, at present one of the largest of its kind in the world, and capable of accommodating the largest vessels afloat, having, of course, pumping machinery of like proportions.

Some interesting figures and diagrams were presented by Mr. Baxter, bearing upon the great efficiency of the machinery, and the record work it had done in the matter of emptying the enormous quantity of water contained in the dock when vessels are being accommodated. A few general particulars may be given respecting the dimensions and capacity of the dock. The principal dimensions are:—Length of floor, 880 ft.; width of floor 81 ft. 8 in.; width at top, 115 ft.; width at entrance, 83 ft.; depth of water on sill at average high water of spring tides, 26 ft. 6 in. The floor of the dock is 2 ft. above the sill, and the length of the dock is divided by a pair of steel hinged gates into two parts, the inner division being 420 ft., and the outer, 460 ft. long. When no vessel is in the dock, and with a tide 26 ft. 6 in. above the sill, its capacity, or quantity of water to be removed, is about 13¾ million gallons, equivalent to 2¼ million cubic ft., or 61,440 tons, which, in accordance with the specified test, had to be emptied in not more than two hours after commencing to pump at top of high water, at the expiry of which time the tide outside the dock was expected to fall 4½ ft. On the official trial, with a tide 26 ft. 3 in. in the outside, and 26 ft. 1½ in. in the inside division, the dock was emptied in 99 minutes, the contractors thus having 21 minutes to spare. This was good work, considering that this was only the second occasion on which they had had an opportunity of trying the machinery under test conditions.

Since that time, however, this record has been surpassed, for with a tide of 27 ft. inside and outside the time has been reduced to 90 minutes for pumping out both divisions without a ship in either of them. This meant the removal of about 66,033 tons of water, the amount in the outer division being about 35,520 tons. If, then, a vessel, displacing, say 10,000 tons, were docked in the outer division only, the quantity of water to be pumped out would be 25,520 tons. The machinery being capable of removing 66,033 tons in 90 minutes, or, roughly, on an average 734 tons per minute, it follows that with a 27 ft. tide the outer division of the dock, which is the larger, could be emptied in somewhat less than 35 minutes. This would probably be found much quicker than there was any need for, especially if a vessel of such a size had to be washed down during the process of pumping, even if it could be adequately shored up in such a short time. It is proving a matter of gratification to the Clyde trustees, and all concerned with the working of the dock, that the performance of the pumping machinery has so much exceeded the test requirements, and reflects such credit on the contractors, Messrs. Andrew Barclay, Sons & Co., Kilmarnock, and Messrs. Gwynne & Co., London, who sub-contracted for the pumps.

Mr. Baxter also pointed out in the course of his paper that through the adjacency of the three docks the older benefited from the new and its powerful pumping equipment. A branch culvert 3 ft. in diameter had been constructed from the 6 ft. filling culvert of the new dock, which communicated with Dock No. 2, an arrangement, he said, which had effected a very great improvement in the working of the latter. Owing to this and other necessary connections the pumping machinery in connection with Dock No. 1 or that of No. 3, or both sets of machinery, could be utilised for No. 2. In this way not only was it emptied much more quickly, but the long delays at the finish had been altogether avoided. This had much enhanced the value of No. 2 Dock, and was an improvement which was, no doubt, fully appreciated by surveyors and superintendents of steamers using it.

A noteworthy and highly useful item in the equipment of No. 3 dock, which was now being provided on the north side, was a 25-ton steam travelling crane with a fixed jib, mounted on a strong steel carriage, having a rail gauge of 24 ft. 9 in., and with a clear headway of 14 ft. 6 in. from top of rails to under side of cross girder. It was capable of travelling by its own power with the jib in any position with a test load of 30 tons on a set of double rails extending the whole length of the outer division, and beyond the division gates, so as to make the crane available for either division. The rake, or overhang, was 74 ft., thus extending well over the centre line of dock, the range of lifting block being from 35 ft. below to 50 ft. above the cope. The driver's house was so arranged that he could always be able to see the bottom of dock.

The Grangemouth Dockyard Co., launched about mid-month the steel screw-steamer *Irene*, built to the order of Messrs. Furness, Withy & Co., of West Hartlepool, for Messrs. M. Hulthen, of Helsingborg, and a sister ship to the *Muriel*, built by the company last year for Messrs. Furness, Withy & Co. She will carry a deadweight of 3,100 tons with Lloyd's summer freeboard, and has a low net tonnage. The dockyard company are at present exceedingly busy, having seven vessels on hand, two of them being large steamers fitted for carriage of oil in bulk.

Three of the steamers of the Laird Line—the *Brier*, the *Cedar*, and the *Azalea*, are at present receiving an overhaul on the Clyde. The *Brier*, which was built 17 years ago by Messrs D. & W. Henderson, Partick, is receiving new engines and boilers with improved passenger accommodation, electric light throughout, electric ventilating fans in 'tween decks, and other improvements. The *Cedar* and *Azalea* are getting a general overhaul, which includes the introduction of electrical light and fans of the Blackman type.

THE TYNE.

(*From our own Correspondent.*)

Shipbuilding.—Since last month nothing has occurred to re-establish a feeling of hopefulness as regards the future of shipbuilding, the surrounding conditions having, if anything, taken on a still more sombre aspect. In most of the great over-sea trades, freights have shown further depression, the downward inclination being evidently caused by the circumstance that the supply of tonnage has largely exceeded the demand. And still the launching of big cargo carriers goes on apace, so that as time goes on the evil of over-supply is likely to be further accentuated instead of lessened. The development of new trades and new countries, on which shipping people depended so much as a means of absorption for the vast carrying mediums they were bringing into existence, has not progressed according to the expectations formed, and hence the fact that a necessarily limited demand could not keep pace with a practically unlimited supply. Yet, despite the circumstance that the demand for new ships is no longer urgent, but is beyond all possibility of doubt declining, there are workmen's leaders so wilfully blind to all that passes as to think the present a suitable time for harassing the employers with demands for advances of wages. On the Clyde it would seem that the carpenters and joiners have asked for an advance, but it has been reserved for the labourers to take the initiative in this movement on the North-East Coast.

The officials of the principal labourers' union (there are three or four different unions claiming a foothold in the northern shipyards) put forward a demand for a ten per cent. advance all round; and, though the employers have had the courtesy to a deputation on the subject, they—in accordance with expectation—decided to grant no advance whatever, as their principal reason the obvious downward tendency e. We dwell upon this episode for the reason that it s an idea of the exaggerated view of their own import- hich even labourers can take when they have succeeded ing themselves into a union. Even if trade were in an akably flourishing condition, an application for an e coming in the first instance from the labourers would, tainty, meet with refusal, as it would have been against edent to begin an advance movement with the lowest class adder. The labourers have always *followed* the mechanics matter of advances, and, for that matter, in reductions d this, of course, is still the natural order of things. The ntatives of the labourers have, in trying to assume a to which they were not entitled either by custom or n sense, inflicted an injury on their constituents, ch as by their action they have raised expectations under the circumstances, could not possibly be realised. g is more unwise on the part of working-class leaders present claims which cannot be sustained by argument; h groundless and usually ill-timed requests, only create a of annoyance amongst the employers, and, if often re- may even provoke resentment. So well established is that the labourers follow the mechanics in all changes s, whether upwards or downwards, that the former could well without a trade union, and it is difficult to see in ay the latter can be of use to them. Union or no union, ages are advanced when the wages of the mechanics are d, and all the unions in existence would not enable extort an advance at any other time.

em of considerable interest to the shipbuilding and ring communities of the North is the fact that Mr. Knight, on his retirement from the position of general y of the Boilermakers' and Iron Shipbuilders' Society, retained as consulting secretary. This is a guarantee the future, as in the past, the action of this important ill be influenced by moderate counsels at the seat of nent, and that the amicable relations so long main- vith the employers will be continued. The nominations position of general secretary, now vacant, are being or in the society's current monthly report, and the will doubtless take place between now and August. tainty that Mr. Knight's hand will—in some sense— e to guide the helm, divests the question of succession of large share of its importance; as the fear that some gued offshoot of the Socialist party might get control of ety, no longer exists. The executive council have put he members a graduated scale, embodying their idea as inimum and maximum salary to be paid to the next secretary, and in this they have gone in direct opposi rade union practice, as the highest figure named by them han the amount paid to Mr. Knight, the present holder office. They actually recommend the members to do ich they would resist to the death were an employer to it against one of themselves, namely, to reduce the ttached to an office; and it is exceedingly strange that body like the Boilermakers' executive should consider n their eyes—would be an act of meanness or tyranny, by an employer, to be an act of expediency and justice ne by themselves.

er stage in a very remarkable piece of work has been ut at the yard of Messrs. C. S. Swan & Hunter, namely, uching of the forward section which has been built y to make whole and sound again the decapitated *Milwaukee*. Our readers will remember that on the of her maiden voyage in September last this vessel en ashore on the Scotch coast, and that subsequently r-part (including the engine and boiler areas) was towed yne, the forward section being irrecoverable. It was tural that the work of constructing a new forward section levolve upon Messrs. Swan & Hunter, who were the builders of the vessel; and they have amply justified ection for the performance of this onerous task by suc- putting into the water the completed section in less e anticipated time. The work of attaching the new to the salved section is still to be done, but this will e particularly difficult, and will doubtless occupy but a days. The whole work of salving and reconstruction tes quite a unique achievement, as, though numbers of have been cut asunder, and put together again after lengthening, never before has a vessel had a new forepart attached.

Messrs. Armstrong, Whitworth & Co.'s yards at Elswick and Low Walker are fully occupied with warships and merchant vessels of exceptionally large size, the latter yard being the busier of the two. The company are still engaged in carrying out alterations intended to enlarge productive scope, and during the past few weeks some important additions have been made to the machinery equipment at each establishment.

Messrs. Wigham Richardson & Co. are also busy with extension work, included in which is the creation of two additional building berths. Among the contracts in hand are three superior-type boats for the Hansa Co., Bremen, and one exceptionally large one ordered for the service of the Austrian Lloyd's.

The Palmer's Shipbuilding and Iron Co., Limited, have received from the Admiralty an order for three out of the twelve new torpedo-destroyers given out to private builders. Considering the number of firms who had competed for this work, the great Jarrow firm may be congratulated on their success in getting so large a share, and the circumstance testifies to the esteem in which the company is held by the powers that be. Messrs. Palmer have, we believe, built more vessels of this type than any other firm on the North-East Coast, or perhaps in the United Kingdom, and the experience gained has enabled them to attain special distinction in the execution of this particular class of work.

Messrs. Hawthorn, Leslie & Co. have also been among the successful competitors for Admiralty work, and the orders they have secured, with the merchant work already in progress, will keep the yard busy for some months to come. Messrs. Dobson & Co. have a good show of work on the stocks, and two vessels in the water being fitted out, a similar state of things being apparent at the yards of the Tyne Shipbuilding Co., Messrs. Readhead, and Messrs. Wood & Skinner. In the smaller yards work is plentiful, and repairing establishments are generally busy.

Engineering.—Our anticipation in last month's "Notes" with regard to the wages question has been verified, the employers having refused to grant the advance asked for on behalf of the operative engineers. The question is now in abeyance, but it is not probable that the engineers will carry the matter to the point of going on strike. Though the wages now current are higher than were ever paid before, the engineers might have been able to push them a point higher had there been no bootless struggle for a shorter working day in 1897; but in that wild attempt to attain the unattainable they effectually overstrained their resources, and rendered themselves quite powerless to do such another injury to trade as they then managed to effect. They will do very well, indeed, if they can retain their present rates of pay over the months of the current year, for it is well known that trade is slackening, and the next change in wages will be inevitably in the downward direction. In these circumstances the less said about advances the better.

Night-work is still continued at all the leading establishments, but it is thought that the time is now at hand when it will be possible to begin a gradual narrowing down of the night and overtime operations. Both overtime and night-work are, to employers, expensive luxuries, which must not be indulged in excepting under the spur of stern necessity. As soon as night-work is brought within appreciably narrower limits than at present exist, labour will become more plentiful, or, what is of equal significance, work will become more scarce, with the result that men of inferior ability or irregular habits will find it exceedingly difficult to find employment.

We understand that the efforts of Messrs. Crosier, Stephens & Co., of 2, Collingwood Street. Newcastle, to create a demand for their engineering and other specialities in South Africa, have already had very satisfactory results, some good orders having been secured, and the gentleman who has been entrusted with the charge of the firm's interests in that country being sanguine as to a further development of business.

Messrs. Clark, Chapman & Co. are extremely busy with the manufacture of marine specialities of various kinds, and in the electrical department of their works business is also prosperous.

Messrs. Thos. Proctor & Son, ship ventilator, tank, and signal lamp manufacturers, metal workers, &c., have just now an exceptionally large number of important orders on hand in connection with the equipment of vessels building on the Tyne and Wear, and at other centres. The extensions at the firm's

Gateshead works are approaching completion, and a good proportion of the new machinery is already in position.

Well-sustained activity is the feature at Messrs. H. Watson & Sons' works, High Bridge, Newcastle, the demand for the firm's well-known Westminster ballast pumps being still very active. The features of this pump are its great strength and simplicity of design, together with the very marked economy of steam effected in its working, as compared with duplex pumps of equal capacity.

Through the instrumentality of Mr. H. M. Wilson, of Crown Buildings Side, a new and interesting marine engine appliance has been introduced into this district. This is Welbury's patent racing check, which is the invention of Mr. W. Welbury, 5, Middleton Crescent, Dewsbury Road, Leeds, and is intended not to displace, but to assist the governor. It effects this object by allowing the steam under certain circumstances to escape direct to the condenser without passing through the engine. It is easy of application to old or new engines, and is suitable to most patterns of marine governors. A report just to hand from the chief engineer of the s.s. *Queen Wilhelmina*, to the machinery of which this appliance has been fitted, speaks of it in the highest terms, as being an invaluable adjunct.

THE WEAR.

(From our own Correspondent.)

WE are pleased to be able to state that Messrs. W. Doxford & Sons have decided to put down an extensive electrical installation of dynamos, motors, &c., for the purpose of driving the machinery in all their departments, as well as for lighting the buildings, yard, and riverside platform at night time. The contract has been given to that enterprising local firm, the Sunderland Forge and Engineering Co., Limited, who are just now engaged in fitting Messrs. Austin's yard with an electrical power equipment, and have the contract for a similar installation at the works of Messrs. Priestman & Co. There are, we believe, three yards on the Wear where electricity is already being utilised for machine-driving purposes, and when these other three are fitted, it will be possible to say that the whole of the leading yards have taken part in the advanced movement. The advantages of electricity, as a motive power, must be looked upon as indisputable when three of the most successful firms on the Wear evince their trust in it by adopting it simultaneously, and we have little doubt that, in the course of a year or two, its adoption will have become general.

It is understood that Sir James Laing & Sons have received an order for a couple of large vessels from a French firm, and they have also some good repair contracts in hand. Messrs. R. Thompson & Sons continue to have their berths fully occupied, and at Messrs. Pickersgill's yard there are three vessels on the stocks. It is understood that at least two of the latter are for Liverpool owners.

Messrs. Blumer & Co. are putting down a very large vessel, which, it is believed, is ordered on foreign account, and at Messrs. Bartram & Sons two vessels of about 6,000 tons capacity each are in course of construction.

Messrs. J. L. Thompson & Sons have their five large berths occupied, three of the vessels being, as yet, in early stages. It is understood that these—or three others—are ordered by a firm on the West Coast. This firm, who are usually identified with every forward movement have, we are able to state, definitely decided to adopt the system of "joggle" plating, patented by Messrs. Doxford, and have ordered a "joggling" machine, or "roller-press," of the largest power to enable them to put their resolution into effect. This will make four firms on the Wear who have adopted "joggle" plating—namely, Messrs. Doxford, Sir James Laing, Messrs. Pickersgill, and Messrs. J. L. Thompson & Sons, one firm on the Tyne (Messrs. Armstrong, Whitworth & Co.), and one at Middlesbro' (Messrs. Cragg & Sons). One or two firms abroad have also adopted the system, which is giving every satisfaction wherever it is in use. It is getting on, but not so rapidly as it should do, considering its obvious merits.

A very fine vessel, recently launched from the North Sands yard, is now being fitted out at the Manors Quay Repairing Works, where a large vessel is daily expected to be generally overhauled for reclassing.

Engineering.—Full activity continues to exist at the marine engine works, and in all cases vessels are being fitted with their machinery, the greatest possible dispatch being used in this operation. One or two of the firms have repair contracts to supplement the new work, and at Palmer's Hill establishment (Messrs. John Dickinson & Sons) the department devoted to the manufacture of Dickinson's patent crank shaft is exceptionally busy.

Messrs. J. G. Moore & Co., of the Vulcan Works, Monkwearmouth, are experiencing a large demand for their patent ash-hoist and other specialities, and with their somewhat limited resources, find it difficult to meet the requirements of customers. Changes, however, are imminent, which it is expected will enable them to largely increase their productive power, and the development of the business generally. At the aluminium and brass finishing works of Mr. Wm. Mills, Bonnersfield, Monkwearmouth, business keeps exceedingly brisk, the demand for cabin fittings in aluminium being steadily on the increase. Mills' boat-lowering gear is also in much request, and a good many important orders are now in course of execution.

The Hartlepools.—Shipbuilding is still very brisk at this centre, and in the engineering works sustained activity is the rule. The local steel works are kept busily going, and can with difficulty cope with the current requirements of customers. At the docks business is still somewhat languid, but timber imports will soon become numerous, and it may be expected that coal shipments will also improve.

Stockton.—The shipbuilding yards continue to be well filled with work, and no appearance of a falling off is yet to be ticed at the engineering establishments. Steel works are still pressed with orders, and in the boiler and bridge building works the briskness previously noted is unimpaired. The weather lately has been unpropitious for out-door work, and some enforced idleness of labour has resulted.

Middlesbro'.—It is understood, that in addition to other work of an important kind, Sir Raylton Dixon & Co. have a large vessel in hand for a line of foreign passenger and mail boats. Engineering works keep busy, and the same may be said of boiler works, foundries, &c. At the docks some signs of improving business are apparent.

Consett.—The works of the Consett Company are kept in full activity, and the weekly output of steel plates, bulks, and angles is maintained at its fullest height.

THE MERSEY.

(From our own Correspondent.)

NOTWITHSTANDING the very considerable falling-off in the weight of new work that is just now coming forward in the principal shipbuilding centres, there is no slackening down at all as regards the activity throughout the marine and general engineering industries of this district. The leading tool-making firms throughout Lancashire continue exceedingly busy, and most of them have orders—a large number of which are for shipbuilding and marine requirements—that will keep them fully going, at any rate, over the remainder of the year. New work also still comes forward freely, and—in the tool-making, boiler-making, and stationary and locomotive engine building trades—in more than sufficient quantity to replace contracts as they run out, whilst hydraulic and electrical engineers in all departments are excessively busy.

The briskness of trade is necessarily reflected in the employment returns of the workmen's unions. The Steam Engine Makers' Society, which covers most of the shipbuilding centres, has only one per cent. of its total membership on donation, whilst in the Lancashire district the unemployed list is practically nil. The United Machine Workers' Association reports about 2¼ per cent. on benefit, and in this district a general average of less than 1½ per cent. In Belfast, Gateshead, Leeds, Glasgow, Stockton-on-Tees, Keighley, Halifax, Grantham, Huddersfield, Doncaster, Bradford, Lancaster, Crewe, Gloucester, Hammersmith, Erith, Woolwich, Edinburgh, Wigan, Loughboro', Grimsby, and Attercliffe, there are no members on support.

Since the publication of our last issue Messrs. Laird Bros., of Birkenhead, have received orders from the Admiralty for two more 30-knot torpedo-boat destroyers. Evidently the Government fully appreciate the many successes which the firm have gained in the construction of vessels of the above-named class.

We had the other day an opportunity of inspecting a special duplex vertical milling machine which is being supplied by Messrs. Cunliffe & Croom, of Manchester, to a shipbuilding yard on the Mersey. This machine is of novel design, and, whilst it is capable of dealing with heavy work as one combined machine, it can be used for lighter operations as two separate machines. The bed is 15 ft. long, with four bearing surfaces to support the tables, which are each 10 ft. long by 3 ft. 6 in. wide, the space between the uprights being 8 ft. The tables are each provided with variable self-acting feed motion in either direction, independent of each other, and a quick return by power in both directions. The tables and heads can be run separately as two machines, each with its own independent driving, feed, and reversing motions, or the tables can be coupled by means of an endless chain, which is easily detachable, and one or both heads put in operation. There is a strong cross slide carrying two headstocks, each of which is provided with independent driving and feed motion horizontally, and also quick traverse for adjustment horizontally and vertically by hand. Two portable circular tables are provided, one on each of the long tables, with self-acting feed, for circular milling. The spindles are of hardened steel, revolving in conical bearings adjustable for wear. The tool is of massive design, and constructed to resist heavy cuts, and the gear throughout is machine-cut. The machine is specially designed for use in marine engineering, locomotive, and general engineering workshops. The firm have also in hand several radial drilling tools, with spindles from 5 ft. to 8 ft. radius, with provision on the headstock to set the drill over to work at any angle up to 45 degrees, and automatic lathes for the production of copper ferrules from the tube up to 6 in. diameter.

Messrs. Hulse & Co., Limited, of Salford, who have just added to their establishment new erecting and machine shops, have in hand a number of specially designed heavy machine tools, a noticeable feature of which is the arrangement that has been introduced for driving direct by electric motors, self-contained with the machine. Amongst these are several powerful lathes, on the firm's patent twin-screw principle, in which the motor is placed on the top of the fast headstock, and the variation of speed obtained through positive gear. The speed of the motor is also capable of variation between certain limits, and by this arrangement the gearing of the headstock is greatly simplified. Other special machines include large tools for boring the barrels and hoops of guns, also arranged for driving by variable-speed motors. In these machines there is a central driving headstock for rotating the work, which is mounted on a base plate, and driven by worm and wheel through spur and bevel gearing from the motor. The base plate also carries a boring bed, on which are mounted a sliding carriage and boring bar holder, which have variable self-acting feed motion, and also quick-power traverse motion for rapidly advancing or withdrawing the boring bar, which is operated by an independent motor at the end of the bed. Other tools to be driven by electric motors are a number of patent double-headed drilling machines, for drilling and tapping holes in armour plates. Each machine has a massive slide bed, and the drill spindles can be readily set to any required position, and adjusted by worm and wheel, to drill holes at different angles. The firm have also in hand several massive armour-plate planing machines for dealing with plates up to 10 ft. 6 in. wide, and 18 ft. long. Other work in progress comprises large gun-boring machine and gun-turning lathes, one of the latter being provided with a special apparatus for wire-winding guns up to the largest size. They have also in course of construction complete plants of patent machines for making the Belleville boilers; a four-spindle machine for boring out the oval holes in the headers of water-tube boilers, and five-spindle multiple drilling machines for making the holes in the drums of the "Yarrow" and "Thornycroft" types of water-tube boilers.

Messrs. Hartcliffe & Malkin, of Salford, have brought out a special design of their patent straight full-way valve, with a solid bottom, to prevent leakage. In this valve a special arrangement of angle blocks is introduced, so designed as to compensate for any slight wear of the valve faces.

A new anti-incrustation composition, for steam boilers, is manufactured by Messrs. John S. Morris & Sons, of Manchester, who are introducing it as a special preparation for neutralising the effects of feed waters containing free acids, such as are to be found in the neighbourhood of galvanising works. This composition, which is termed "Pherokalsene," has been used with signal success in several works where the only feed water available contained large quantities of acids, whilst it is also effective in dealing with feed waters containing abundance of silica and iron in combination.

Messrs. W. H. Bailey & Co., Limited, of Salford, have purchased the Ellesmere Foundry, Patricroft, for the purposes of branch works, where they are putting down modern labour-saving plant, and also for the manufacture of Foster patent reducing valves, of which they are making a large number, from ½ in. to 18 in. diameter.

In the iron trade a strong tone prevails generally, and during the past month prices have shown a substantial upward move, both for raw and manufactured material. In pig iron a good steady inquiry comes forward. For local and district brands orders offering have been more than makers can entertain. Lanc maker. hav. withdrawn quotations and district brandshave advanced about 2s. a ton. No. 3 foundry Lincs. is now quoted 55s. 6d. net; and Derbyshire, 57s. net delivered Manchester; with forge qualities, delivered Warrington, about 53s. 8d. net cash for Lincolnshire. In outside brands prices during the month have been rather irregular, but towards the close they have hardened up about 2s. per ton. Delivered by rail Manchester foundry Middlesbrough 59s. 4d. to 59s. 10d. net cash, with Scotch iron, at the Manchester docks, about 61s. to 62s. 6d., and ordinary American foundry brands about 57s. to 57s. 6d. net cash.

In the finished iron trade a brisk tone characterises business, and there has been an all-round advance in prices. Official list rates for bars have been raised 5s. per ton, £7 being now the minimum for Lancashire, and £7 5s. for North Staffordshire qualities, with a lurther advance asked on actual business. Sheets are also stronger, and now quoted about £8 2s. 6d. to £8 5s, List rates for hoops have been advanced 5s. per ton, which now brings them up to £7 5s. for random and £7 10s. for special cut lengths delivered Manchester district, and 2s. 6d. less for shipment. Merchants have put up their stock prices for all descriptions of manufactured iron and steel 10s. per ton.

Nut and bolt makers have advanced their minimum list rates 10s. per ton.

In the steel trade there is no material change to report, and with the exception of some irregularity in quotations for boiler plates, prices are generally very firm at full late rates. No. 3 foundry hematites range from 70s. to 72s. less 2½; billets, £5 2s. 6d. net; bars, £7 10s. to £7 15s.; common plates, £7 15s. to £7 17s. 6d.; boiler plates have been sold as low as £8 10s., but the general quotation is £8 15s., delivered Manchester district.

Business comes forward freely in the metal market, which is quickly recovering from the downward tendency reported last month. List rates for brazed brass tubes, brass wire and rolled metals, have been put up ½d. per lb., and copper wire 1¼d., and quotations for delivery in the Manchester district are now as under: solid-drawn brass boiler tubes 8¾d.; solid-drawn brass surface condenser tubes, 10¼d.; solid-drawn copper tubes, 11d.; brazed copper gas and steam tubes, 10¾d.; brazed brass tubes, 10d.; common rolledb rass, 8¼d.; common brass wire, 8½d.; copper wire, 10¼d. per lb.

The timber trade is rather quiet. The arrivals however, generally have been only moderate, and deliveries fairly satisfactory. Stocks as a rule are not too large, and values steady. For teak squares, with light arrivals, and an increased enquiry, prices are firm, and stocks moderate. Planks have arrived freely, but there is a good demand, and stocks are not excessive. The consumption of greenheart has been small, and stocks are sufficient, with prices unaltered.

In the coal trade all descriptions are in brisk request, and, in the lower sorts especially, the demand is greatly in excess of the output. Business in the better qualities of round coal is exceptionally good for the time of the year, and prices are exceedingly firm at the full list quotations. The activity throughout the iron trade and other manufacturing industries is keeping up a large demand for the lower qualities of round coal suitable for steam and forge purposes. In many cases collieries, as already mentioned, are short of supplies to provide for the deliveries required by their customers, and prices tend to harden, 9s. being readily obtainable for good qualities at the pit's mouth. With regard to the gas coal contracts for the ensuing season, a strong combination of coal owners has been formed with the object of keeping up prices, and they are holding out for a general advance of 1s. 6d. to 2s. per ton over last year's rates. On the locomotive fuel contracts an advance of 1s. 6d. is also being held out for, and it is reported that the contracts have been practically settled on this basis. Engine fuel is in brisk demand, with supplies short and new business difficult to place. Prices are firm at the recent advance, common sorts averaging 5s. 3d. to 5s. 6d.; medium 5s. 9d. to 6s.; best 6s. 6d. to 6s. 9d. at the pit.

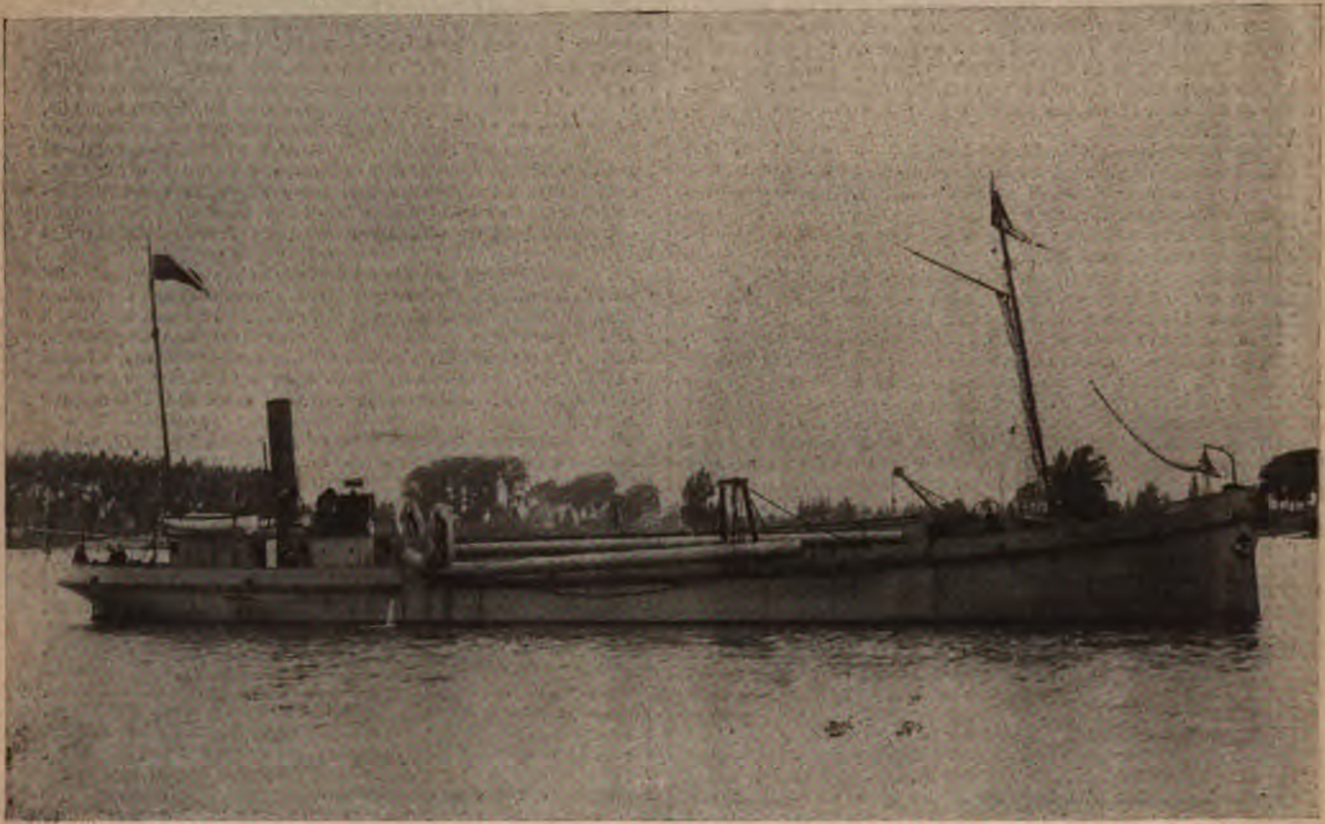
Shipping is fairly active, with ordinary steam coal averaging about 9s. 6d. to 9s. 9d. at the Garston Docks; 10s. High Level, Liverpool; and 10s. 3d. to 10s. 6d. Partington tips, Manchester Ship Canal.

THAMES.

(*From our own Correspondent.*)

R. & H. Green & Co.—There is a fair amount of work at the Blackwall yard. The Great Eastern Railway have sent their two paddle steamers there to get a general overhaul, the engines for the same undergoing similar treatment at John Penn & Sons'. Then on the stocks six steel barges are being built, and there is also a large tank under construction for the London and India Joint Stock Company.

The Thames Iron Works, Limited.—The two first-class battleships the *Duncan*, and the *Cornwallis*, are now fairly under way, and they are expected to keep the place going for at least three years. Their dimensions are 405 ft. in length, 75 ft. 6 in. beam, and 26 ft. 6 in. draught. They are of 14,000 tons, and 18,000 I.H.P. Their armament consists of four 12-in. breech-loading guns, two barbettes, twelve 6-in. quick-firing, in casemates, twelve 12-pounders, six 3-pounders, and four torpedo tubes. The engines are triple-expansion, and they are to be fitted with Belleville boilers. The Agent-General of the Cape of Good Hope has ordered a pontoon for the St. John River, and three barges of steel and iron for the same. There are also on the stocks ten barges for private firms. As mentioned in the speech made by Mr. Hills not long ago, the Thames, Limited, with their eight-hour day system, have obtained all the work for the National Lifeboat Institution, and at the present time some five boats are being built.



THE DREDGER "TITUS EDRIGEVITCH."

John Stewart & Son, Limited.—The dredger *Titus Edrigevitch* has steamed out to Archangel by her own power; and at the pumping trials the hopper was filled with 1,000 tons of sand in twenty-five minutes, which was well under the contract time, and the officials of the Russian Government are pleased with the results. The dredger is 183 ft. 10 in. in length, 32 ft. 9 in. beam, and 13 ft. 10 in. depth, moulded. It has a capacity for 500 metrical tons, and when the draught is normal, 11 ft. 11 in., the speed is 8 knots an hour. There are ten bulkheads extending to the upper deck. There are three ways of discharging: first into the hopper wells, second into barges, and third through tubes on to the shore. The crew's places are heated with steam. The dredger is also fitted with the electric light, and there is a search-light projector. The dredging is performed by means of two centrifugal pumps, and these are driven from the fore ends of the shafts of the propelling engines by clutch gearing; the suction is jointed to the ship's side, and arranged that it can be raised and placed on deck.

The General Engineering and Boiler Company have under construction the compressors for the *Drake*, and also the refrigerating machinery of the Japanese cruiser. The air compressors of the *Irresistible* are also being made, and both the refrigerating machinery and the air compressors of the *Implacable* are under construction.

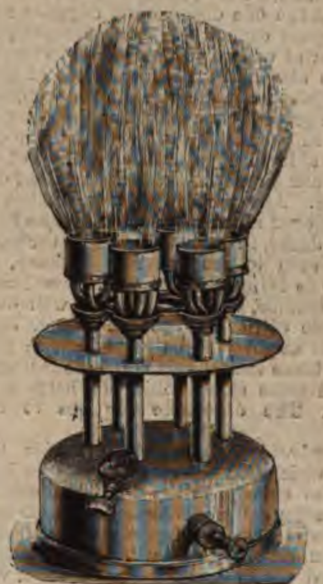
Messrs. Maudslay, Sons & Field, Limited have had interesting notices in respect to their Belleville boilers in the ordinary Press. The *Daily Mail* has been devoting itself to the burst tubes of the *Terrible*, and the *Pall Mall Gazette* has pointed out a few things on the Parliamentary position. Says the *Pall Mall Gazette*: "The matter is one of profound importance to the country, for immense sums have already been spent upon these contrivances, and more is about to be spent. Moreover, the boiler cannot be considered as apart from the ship; and, if the cost of the vessels affected be taken into consideration, the figures run to many millions. Under these circumstances, the statement made by the First Lord is very grave." After the policy of the Admiralty was stated by Sir William White and Sir John Durston to be the fitting of the fleet throughout with water-tube boilers, the First Lord says: "The whole question of the value of water-tube boilers is still under consideration;

the Admiralty engineers still have 'open minds'; the expression of a categorical opinion at this stage would be premature." Says the *Pall Mall*: "Experiments should be made with one or two ships at the utmost, and not until those experiments have been conducted with absolute success, and over a long period, should the nation be committed to the expenditure of millions. Whether the Belleville boilers be good or bad remains to be proved; so much may readily be conceded to the Admiralty. But to claim the benefit of the admission is to plead guilty to a grave error of judgment." But the *Pall Mall* gives itself away on the question of solid-drawn or welded tubes. "Parliament," says the *Pall Mall Gazette*, "was given to understand that the tubes of the *Powerful* and *Terrible* were the same as those of the *Sharpshooter's* boilers. The tubes of the *Sharpshooter* were solid-drawn; those in cruisers were welded. They were not the same, and the recent explosion has shown that the discrepancy was most material." There is one question the *Pall Mall* might answer for us. Did the tubes of the boilers of the *Terrible* explode at a seam of the welded tube?

This firm has also fitted the main engines of the new cruiser *Spartiate*. They are to be of the same dimensions as the engines of the *Diadem*, but instead of 16,500 H.P., they are to develop 18,000 I.H.P. The boilers are not to be larger, but have to give increased evaporation from increased heating surface. These engines are of the four-cylinder triple-expansion type, the cylinders being set in the following order—low, high, intermediate, and low pressure reckoning from forward; their diameters are 64 in., 34 in., 55½ in. and 64 in., stroke 4 ft. The cylinders are steam-jacketed, their working barrels being made of close-grained cast iron. The valves of the high and intermediate pressure cylinders are of the piston type, while the double-posted flat valves are fitted to the low-pressure cylinders. All the valves are fitted to double eccentric and twin-bar links. The cylinders are supported on four cast-iron double-legged columns, at the back of the engines, these are bolted together in pairs at their feet, the front supporting columns being of forged steel turned. All of them, says the *Engineer*—at front and back—being carried by and firmly bolted to the cast-steel main bearing brackets, which are connected together at their ends by girders, and the whole firmly secured to the engine-seatings worked up from the ship's frames. The crank shafts of the engines are of steel, the dimensions of the crank-pins being 1 ft. 7 in. diameter and 1 ft. 9 in. long, the crank shaft bearings each 1 ft. 5½ in. and 11 in. long. The high-pressure crank is at right angles to the intermediate-pressure crank, and low-pressure crank (aft) at right angles to low-pressure crank (forward). The propeller shaft is 17½ in. diameter, and the turret shaft, 16¼ in. diameter. They are all hollow, with a 9 in. diameter through them. The thrust blocks have collars of the horse-shoe type lined with white metal. Each set of engines has an air pump, 2 ft. 6 in. diameter and 27 in. stroke, driven off the high-pressure piston rod crosshead. The condenser has 9,500 square feet of cooling surface, the water for cooling being supplied by centrifugal pumps 3 ft. 9 in. diameter, driven by independent engines. The screw propellers are 17 ft. diameter, and the pitch ranges from 19 ft. to 22 ft. There are thirty water-tube boilers, each fitted with an economiser. They are placed in groups in four compartments, or boiler-rooms, three containing eight boilers each, and the forward compartment containing six boilers. Each boiler has one fire-grate with three fire doors to it. They are placed in a fore and aft direction, thus preventing the roll or list of the ship affecting the level of the water within them. The tubes of the boilers are 4½ in. external diameter, and in the economisers 2¾ in. diameter. The boiler tubes are ⅜ in. thick, while in the economisers they are ·16 in. They are steel, and solid drawn. They are worked at a pressure of 300 lbs., which is reduced at the engines to 250 lbs. The temperature at which the feed leaves the economiser is from 240 deg. to 250 deg. Fahr. The grate surface is 1,390 square feet, and the total heating surface, in all the boilers, is 47,282 square feet. It is estimated that the engines will make 120 revolutions per minute and give a speed to the vessel of 21 knots per hour. The coal bunker capacity is 1,000 tons, but an extra 900 tons can be taken. About sixty auxiliary engines are being made by Messrs. Maudslay, Sons & Field. The firm have the following orders on hand, April 24th, 1899:—1 set of twin-screw engines for H.M. battleship *Irresistible*, 15,000 I.H.P.; 1 set of twin-screw engines for H.M. battleship *Venerable*, 15,000 I.H.P.; the above are in a state of erection in the shops. 1 set of twin-screw engines for H.M. first-class cruiser *Spartiate*, 18,000 I.H.P.; being erected on board at Pembroke, now approaching completion. 1 set of twin-screw engines for H.M. battleship *Albion*, 13,500 I.H.P.; being erected on board at Victoria Docks, now approaching completion. 1 set of twin-screw engines for H.M. second-class cruiser *Gladiator*, 10,000 I.H.P. Trials successfully completed in February last. Mean speed attained 19·1 knots per hour (8 hours' trial). All the above vessels are fitted with Belleville boilers; all but H.M.S. *Gladiator* with economisers.

The bursting of the tubes in the Belleville boilers of H.M.S. *Terrible* cannot fail to be of interest to Messrs. Maudslay, Sons & Field. Five tubes burst in all, but the last burst was the worst, and this was fairly high up in the flattened spiral. The tubes were lap-welded, and had undergone a test of 1,000 lbs. to the square inch, and the boiler had been tested to 360 lbs. to the square inch. Charles Warburton, in his evidence, said it was usually the fourth or sixth tube up from the fire which burst. The bursting took place when the furnace doors were opened.

Messrs. Mceller & Condrup's have on view at their show-rooms, 78, Fore Street, E.C., a new and simple burner for industrial purposes, such as steam raisng. The one shown in the figure has six burners, but they are made with from one to twelve burners. The lamp oil is contained in the cylindrical brass vessel. To start the burner, methylated spirit is poured into little saucers round it. When lighted, it heats up sufficiently to vaporise the oil, and this ignites at a little hole at the top of the main vertical tube. It maintains the main body of the burner at the temperature necessary, and the oil is driven up by pumping it by means of the little pump shown by the knob at the side. There is also in the filling plug a little air-valve C. The flame is put out by reducing the pressure in the cylinder by opening the air-valve.



Mr. C. H. Bryant, of Chiswick, has invented a new oil engine which has been fitted into a launch, and successfully tried at Chiswick. The dimensions of the launch are 40 ft. long by 6 ft. 6 in. broad, and draught 30 in. The cylinders of the engine are 4 in. diameter by 10 in. stroke, and they run at 300 revolutions per minute, the speed of the launch at this rate being nine miles an hour. It is claimed that with this engine there is a continuous explosion and expansion to the end of the stroke. To start the engine, a blow lamp is put outside of the mixing chamber which heats it, and when heated the engine can be started. The blow lamp is taken away, and it is then self-firing. The exhaust finishes with a flame, and there is no deposit. The covered-in space for the engines is 28 in. by 38 in. The engine takes the place of a compound steam-engine of 23 I.H.P., which would have occupied the space of 13 ft. by 6 ft.

BELFAST.

(From our own Correspondent.)

THE shipbuilding and engineering industries continue as brisk as ever, and during the past month negotiations for advances in wages have been going on, resulting in certain classes of workmen obtaining the rise in the two principal yards here. Platers' helpers receiving an advance of 2½ per cent., and there is also an advance of 2½ per cent. on piece-work rates, whilst iron sorters, stagers, and labourers in both shipyards and engine works have been advanced sixpence per week. At the present time riveters, for certain classes of heavy work in the yards, cannot be got at any money, and this will undoubtedly impair the output of the tonnage of the port.

But one launch has taken place during the past month, and this was the *Ping Suey*, from the north yard of Messrs. Workman, Clark & Co., Limited. She has been especially built for the Oriental trade of the China Mutual Steam Navigation Co., Limited, of London.

This same firm have also despatched another vessel during the month, this being the s.s. *Yangtsze*, which, after a most successful trial trip, left Belfast Lough for the Clyde, there to load cargo for a Chinese port.

Messrs. Workman, Clarke & Co., Limited, have at present either eight or nine large steamers on hand, with an aggregate tonnage of between 60,000 to 70,000 tons. But we continue to hear complaints about the scarcity and irregular attendance of certain classes of workmen. This is very detrimental to the work of shipbuilding, as the one department depends so much on the other that progress cannot be made as rapidly as wished, and the completion of vessels is accordingly very much delayed. This firm have also had an extensive lot of shipbuilding and engineering repairs in hand since the year commenced; indeed, they are at the present time enlarging their shops and augmenting their tools in the repairing department, in order that they may be more able to cope with this class of work; but the greatest drawback here just now is for want of graving dock accommodation. As a proof of this, during the past week men have been employed night and day on repairs in more than one of the graving docks, in order to facilitate the relays of steamers waiting their turn to get in. For instance, at the present moment there is lying adjacent to Messrs. Harland & Wolff's yard the s.s. *Oceanic*, which is getting well on towards completion; outside of her is the s.s. *China*, belonging to the P. & O. Co. It might just be remarked, in passing, that the comparison of these two vessels, when seen alongside, makes the *China* look like some small collier discharging coals on board the leviathan. The difference requires to be seen to be believed.

The s.s. *Cambronian* at present occupies the Alexandria graving dock, which was but recently vacated by the *Germanic*. The *Cambronian* belongs to the Dominion Line, and is being fitted with superior cabin accommodation; and after the various saloons, staterooms, and smoke-rooms are finished, she will be placed on dated passenger sailings. The s.s. *Germanic* is being pushed forward with all possible speed, and will ere long be again on her regular passenger trade between Liverpool and New York. It is stated that it took £6,400 to raise this vessel from the bed of the Hudson River. The s.s. *China* is intended to occupy the dock next in turn. It is expected she will take a long time to repair, but no one can yet tell what her bottom will be like after her prolonged seat on the rocks at Perim for several months. But the fact that she made the passage home under her own steam, and only accompanied by two tug steamers, in case of accident, speaks volumes for the strong construction of her hull; but what with costs of salvage operations, towage, &c., and the cost of her repairs here, it would be interesting to know the amount of the bill this ship will cost.

Messrs. Harland & Wolff, Limited, have also the *Afric*, of the White Star Line, on hand. This steamer has returned to this port in order to be fitted with large and improved refrigerating machinery, which could not be got forward in time to be placed in the ship when she was built by the firm. She is also getting some minor alterations and overhauls, and will soon be at her station again. Alongside of her is the s.s. *Medic*, a sister ship, also being fitted out. Altogether, docks and wharfs here are crowded with very large steamers under repair and fitting out. We understand, too, that Messrs. Harland & Wolff have two steamers under construction for the Union Co., but these, as well as others, have been sadly delayed, owing, as already mentioned, to the want of rivetters; besides, as explained in the past number, the plates, rivets, &c., of these large vessels cannot be manipulated by hand, and it is this heavy work that the men so much object to.

A great falling off in enquiries for steamers is reported from various shipbuilding centres, and it is generally thought that a reaction has already set in; but we sincerely hope there is no foundation for these rumours.

Local land-engine makers and foundries are still well employed; but, as there is a great depression in the other principal trades of this city, the town is almost dependent on the shipbuilding industry.

NORTH-WEST OF ENGLAND.

(From our own Correspondent.)

Barrow.—There is very great activity observable in the shipbuilding industry of this town, and since the Easter holidays there has been a further increase in the number of men employed, and a gradual expansion in the several departments of the concern of Vickers, Sons & Maxim at the Naval Construction Works. No new orders have been booked except one for the Admiralty in the form of one of the twelve 30-knot torpedo-boat destroyers to be built by private builders. Possibly Vickers' would have secured more of this type of order had it not been that their hands are already very full with Admiralty work of the largest and highest class. All the torpedo-boat destroyers built here have turned out very satisfactorily, and the more so has this been the case since Vickers' took over the yard and supplied the ships with their special steel for engineering and other work, which has shown itself so very trustworthy in all cases where good, reliable metal was required for special purposes. The demand for ordinary shipbuilding tonnage is comparatively easy, probably on account of the very much higher range of prices now ruling for shipping making new boats almost a prohibitive luxury, except in cases where absolute necessity steps in, and a good market is open in heavy freights for costly boats. Consequently more attention is devoted in the Barrow Yard at present to Admiralty work generally, and in this respect Messrs. Vickers have their hands well filled. The only commercial tonnage jobs Messrs. Vickers have in hand at present are the second of two West African Steam Navigation Co.'s steamers, the *Bornu*, which is to be launched on the 9th of May. Her sister ship, the *Sokoto*, left Barrow at the beginning of April and had her trial trip between Barrow and Liverpool and passed through it very creditably. The engines were worked by degrees up to full speed, in a heavy sea, and the speed of the steamer was much in excess of her specified requirements. The owners are very pleased with the ship. Certainly new engines never started under more satisfactory conditions. The second commercial order in hand is that of the Pacific Steam Navigation Co.'s steamer *Ortono*, which is to be launched in June, and the third commercial order in hand is that for the supply of a Clan Line steamer, so that at the present rate Messrs. Vickers will soon be rid of all commercial tonnage. They intend to pay great attention to Admiralty work of every class, and are extending their yard considerably in area, and increasing its mechanical equipment generally, in order to do not only a much greater volume of work, but to turn the same out with the greatest possible expedition. The shipbuilding yard is being nearly doubled in size, and, when this addition is put to the present yard, and fully equipped with mechanical appliances, it will be possible for the firm to undertake every variety and every size of work. The old yard will naturally be devoted to the building of heavy ships, and the new part to the building of lighter craft, because in the case of the latter the launching area is not so wide; but that could be modified by building the vessels at a different angle in the yard, as is done in many cases on the Clyde and elsewhere where the construction of big ships is undertaken in small yards. The launch of H.M.S. *Vengeance* has been definitely fixed for July 25th next, and will doubtless be the occasion of a very big function, seeing this is the first battleship ever built in the history of the shipbuilding trade by one firm absolutely out of their own resources; for Messrs. Vickers are not only building this ship, but providing it with armour-plates, guns, gun-mountings, ammunition, engines, and every appliance required for its full fighting equipment at sea. The *Vengeance* at present represents something like 7,000 tons deadweight, but she lies on very solid and well

nd, and her successful launching can very easily be
n at so great a deadweight. Much progress is being
the first-class cruisers *Hogue*, *Euryalus*, and *King*
rs. Vickers are amongst the firms who have tendered
new cruisers, first-class, required by the Admiralty
builders this year. The new Japanese battleship
Barrow is to be named the *Mikasa*, and not *Nikasa*,
y reported. She is getting well up in frame, and
ery ponderous ship, being 15,000 tons deadweight
Much satisfaction and credit is felt in Barrow at the
successful official trial trips of the first-class cruiser
protected, built at Barrow. She has beaten all
o economic coal consumption in the Admiralty's
and it is noteworthy that, while she fulfilled all con-
engines and boilers, which worked faultlessly and
tch, had much reserve of power undeveloped. The
the greater to the Barrow firm because the *Amphi-*
ing the records, beat her sister ship the *Niobe*, built
hich previously held the record. Very great credit
r. Adamson, the general manager of the Barrow
r. McKechnie, the engineering manager, for the very
btained. They have been heartily congratulated
building and engineering world generally, and they
ainly a very high tribute of honour.

Caird.—The death occurred in the middle of
David Caird, at his London residence in West
at the age of 53 years. He was for several years a
t Barrow, at the Graving Dock shipyard, and there,
with various partners, built several small steamers.
rs he devoted himself to contracting work, and
gaged in the direction of the Kerosine Oil Co.,
Steel Plant Co., Limited, the Furness Foundry
ring Works, at Barrow, and in many other
ncerns. At the time of his death he was engaged
er things in the building of over 100 houses on Old
nd.

en.—A wail comes from Whitehaven every now
ut the restarting of the old shipyard at this place.
out that a place like Londonderry can resuscitate
ling industry by reopening its yard after being closed for six years, and the question is asked, Why should not Whitehaven do likewise? There is no reason in the world, except the want of local enterprise. Once that is awakened, and the Whitehavians have the courage to engage a good, practical manager, in whom they can place full confidence, and allow him full scope at his work, the chances are that Whitehaven will be found to be as good a place for shipbuilding as any other.

Shipbuilding Material.—The demand for steel shipbuilding material is very briskly maintained, and the orders offering to makers in this district show an increase in volume; indeed, some shipbuilders have very pressing requirements, and are anxious to ensure very full deliveries at the soonest possible date. It is found necessary in the present congested state of the market to send out specifications for material under delivery contract much earlier than some time ago, in order to ensure attention in time. Both the heavy and light plate mills are very busily employed, and many more orders could be obtained if makers could undertake them. Arrangements are, however, in progress for the augmentation of the output of plates by the erection of additional Siemen-Martin's furnaces, and the provision of more powerful stabbing mills, so that the mills can be readily fed with materials, and their output thereby increased. Prices are very steady and firm at £7 2s. 6d. for heavy steel plates, and £8 2s. 6d. for light plates. It is contemplated to put an angle mill at the Barrow Works by taking out an old rail mill. This would be a very wise step, because Barrow is splendidly situated for a large and profitable business in angles, and in every class of shipbuilding material, and it is felt that the more attention that is shown to Siemen-Martin's steel manufacture here, and the less there is shown to Bessemer, the better will it be for makers and for the trade of the district generally. There is a brisk and a growing business doing in heavy and light steel castings for shipbuilding and engineering purposes, and the recent enlargement of this department at the Barrow Steel Works has been more than justified already.

West Cumberland.—The shipbuilding trade in the West Cumberland district remains very busy, and builders have on hand a very fair number of orders. Particularly so is this the fact at the yard of Williamson & Son at Workington, in which a large number of small craft are built, and where there is never any scarcity of work. The trade at Maryport is not so brisk, but that is not on account of any weakness in the market or any scarcity of orders. Latterly, Messrs. Ritson & Sons have kept their yard fairly low down in orders, although they have never suspended operations. It is expected, however, now that there is so much life in shipbuilding, a more active trade will be undertaken at Maryport in the building of small craft.

Hematites. — The hematite pig-iron trade is very busily employed, and there are indications that a much more active market will soon be experienced, as America is likely to become a large customer for North-West hematite metal. The orders held are numerous, and with a slight improvement in the demand a famine would arise. Warrants have been temporarily depressed by reason of bearing operations which have failed. They are now quoted at 61s. per ton net cash sellers, 60s. 11d. buyers. Makers quote 60s. to 61s. per ton for mixed Bessemer numbers. Stocks of metal have slightly increased during the month, and now stand at 221,669 tons, or about 45,690 tons more than at Christmas last.

Shipping.—The shipping trade this year has not been as briskly employed as in the previous year, and the tonnage of exports of metal shows a falling off. The aggregate for this year so far has reached 133,426 tons of pig-iron and 143,772 tons of steel, as compared with 150,178 tons of pig-iron and 164,280 tons of steel, showing a decrease of 16,752 tons of pig-iron and 20,506 tons of steel. Freights are fairly well maintained, and it is probable that shipping will soon be busier, as heavy foreign cargoes are expected to be cleared.

The Akebono (Dawn), the third of six torpedo boat destroyers being constructed for the Imperial Japanese Government by Messrs. Yarrow & Co., Limited, was successfully launched at the works of the builders at Poplar, on Tuesday, April 25th, in the presence of Admiral O. Matsunaga, Inspector-General for the Japanese Navy, Constructor-Commander Kondo, Constructor Captain Kurobe, and other Japanese officials. The guaranteed speed is 31 knots on a three hours' run, carrying 35 tons.

LAUNCHES AND TRIAL TRIPS.

LAUNCHES—English.

Scotsman.—On March 10th there was launched at South Shields, for Messrs T. Gray & Co., of Hull, a steel steam ketch of about 105 tons, named the *Scotsman*.

Yomoana.—On March 11th there was launched at Sunderland for Messrs. Tyser & Co., of London, a steel schooner-rigged steamer, of about 5,648 tons, named the *Yomoana*.

Cleopatra.—On March 13th there was launched at Hull for the Hellyer's Steam Fishing Co., Limited, of Hull, an iron steam ketch, of about 193 tons, named the *Cleopatra*.

King Alfred.—On March 13th there was launched at Grimsby, for the Monarch Steam Fishing Co:, Limited, of Grimsby, a steel steam yawl, of about 159 tons, named the *King Alfred*.

Kathleen.—On March 16th there was launched at Selby for the Central Steam Fishing Co., Limited, of Grimsby, a steel steam ketch, named the *Kathleen*.

Beatrice.—On March 23rd Messrs. D. Banks & Co. launched at Plymouth the lighter, *Beatrice*, 60 ft. long by 20 ft beam and 8 ft. depth of hold, for the Queen Anne's Battery Trading Co., timber importers and merchants.

Mont Blanc.—On Saturday, March 25th, Sir Raylton Dixon & Co., Limited, launched from Cleveland Dockyards, Middlesbro', a fine steel screw steamer built to the order of the Societe Generale de Transports Maritimes a Vapeur, of Marseilles. She is built to Lloyd's highest class spar-deck rule, and has a deadweight carrying capacity of about 4,650 tons, on a light draught of water. Her principal dimensions are:—Length, 331 ft.; beam, extreme, 44 ft. 8 in.; depth, moulded, 25 ft. 9 in. The spar and main decks are of steel with poop, bridge, and forecastle decks of pitch pine, five watertight bulkheads, cellular double-bottom for water ballast, deep framing, &c., with officers' accommodation in houses on bridge deck. She will be fitted with triple-expansion engines built by the North-Eastern Marine Engineering Co., Limited, Wallsend, having cylinders 23 in., 36½ in., 62 in. by 42 in., with two large single-ended boilers working at 180 lbs. pressure. On leaving the ways she was gracefully named *Mont Blanc* by Miss Alice Cohan, daughter of Mr. E. A. Cohan, of Liverpool.

Gadsby.—On March 27th Messrs. Ropner & Son, Stockton-on-Tees, launched a steel screw steamer of the following dimensions, viz.:—Length between perpendiculars, 336 ft. 6 in.; breadth, extreme, 46 ft. 6 in.; depth, moulded, 27 ft. 3 in. The steamer has been built to the order of Messrs. R. Ropner & Co., West Hartlepool, and is of the three-decked rule, with full poop, very long bridge, and topgallant forecastle. The saloon and cabins for captain and officers will be fitted up in the poop, the accommodation for engineers in iron houses on the bridge deck, and the crew in the forecastle as usual. She has double bottom on the cellular principle for water ballast, and will carry about 6,000 tons on Lloyd's summer freeboard, on a light draught of water. She will have all the most recent appliances for the expeditions and economical loading and unloading of cargoes, has direct steam windlass, steam-steering gear amidships, with powerful screw gear aft, six large steam winches, to which steam is supplied by two large vertical donkey boilers, stockless anchors, &c. She will be fitted with a set of triple-expansion engines by Messrs. Blair & Co., Limited, having cylinders 24 in., 40 in., 66 in. by 45 in. stroke. The christening ceremony was gracefully performed by Miss Walker, of Owton Fence House, Greatham, who gave her the name of *Gadsby*.

Highgate.—On March 27th Messrs. S. P. Austin & Son, Limited, launched at Sunderland, to the order of Messrs. William Cory & Son, Limited, of London, the steel screw steamer *Highgate*. The dimensions are:—Length, 268 ft.; breadth, 37 ft. 7 in.; and depth, 19 ft. 9 in.; and she will be classed 100 A1 in Lloyd's register, the deadweight carrying capacity being about 2,600 tons. The machinery will be supplied by Messrs. George Clark, Limited, and is of the tri-compound type.

Algoma and **Andes.**—On March 28th there was launched at North Shields, for Messrs. J. & G. Alward, Limited, of Grimsby, two iron steam ketches, of about 156 tons gross each, named the *Algoma and Andes*.

Britomart, H.M.S.—On March 28th Messrs. W. H. Potter Sons launched at Liverpool the second of two shallow-draugh twin-screw, teak-sheathed steel gun-boats which have been buil to the order of the British Government for use in the Africa rivers. The vessel, which is named the *Britomart*, is a siste ship to the *Bramble*, and is one of four of the *Thistle* class, tw being built by Messrs Potter, the other two on the Clyde. Th dimensions of the *Britomart* are as follow:—Length betwee perpendiculars, 180 ft.; length over all, 187 ft. 6 in.; beam extreme over wood sheathing, 33 ft. The machinery consist of two sets of triple-expansion, three-crank engines, and tw Yarrow water-tube boilers. This will be the last vessel built Liverpool, as Potter's yard has been acquired by the Doc Board for the extension of Queen's Dock.

Anglo-Australian.—On March 28th this large and handsomely modelled steel screw steamer, built for Australian trad to the order of the Nitrate Producers' Steamship Co., Limited, London, of which Messrs. Lawther, Latta & Co. are th managers, was launched from the works of Messrs. Shor Brothers, of Sunderland. This vessel, which is constructed steel throughout, has been built under special survey to th highest class in Lloyd's register, and is of the following dimensions:—Length, 370 ft.; breadth, 48 ft.; and depth, moulded, 30 ft. with a large deadweight and carrying capacity. The erection on deck consist of full poop, long bridge amidships, and topgallant forecastle. Large and commodious deck houses ar fitted on the bridge deck for the accommodation of captain officers, and engineers, with large and handsomely fitte saloon, the panelling being in polished hardwoods tastefull arranged. On the flying bridge deck, a large and commodiou teak wheel and chart house is fitted, the steam-steering gear i fitted in the engine-room with controlling rods to wheel hous and flying bridge. The crew are berthed in the forecastle which is divided by a passage way, and further divided fo petty officers, &c. The double bottom is constructed on th cellular system subdivided into trimming tanks, the peaks als being fitted for water ballast. The holds are four in number which for rapid loading and discharging have been fitted wit eight powerful steam winches, steam for which is supplied by large multitubular donkey boiler placed in the stokehold. In addition, the vessel is fitted with all the newest appliances fo despatch and the economical handling of cargoes. A complet electric light installation is also fitted. On leaving the way the vessel was named *Anglo-Australian*, the ceremony bein performed by Miss Short, of Ashbrooke Hall, who was handed very handsome present by one of the directors on behalf of th company. The vessel is to be fitted with triple-expansio engines by Messrs. George Clark, Limited, of Sunderland having cylinders 26 in., 42 in., 70 in. diameter, with a stroke 48 in., and two large steel boilers of 180 lbs. working pressure fitted with Howden's system of forced draught.

Loch Linthrathen.—On Tuesday, March 28th, there wa launched from the yard of the Tyne Iron Shipbuilding Co Limited, of Willington Quay-on-Tyne, a steel screw steame built to the order of the Dundee Loch Line Steam Shippin Co., Limited, of Dundee, and of the following dimensions:—Length, 320 ft.; breadth, 48 ft.; depth, 23 ft. 6 in., and class 100 A1 at Lloyd's on the single-decked rule. This vess has water ballast fitted right fore and aft on the cellula system, and is also fitted with all modern improvements for th rapid loading and discharging of cargo, including six doubl cylindered steam winches, direct-acting steam windlass, larg donkey boiler, steam-steering gear by Messrs. Alley MacLellan, Limited, and Hasties' screw gear aft. The engines which are to be supplied by the North-Eastern Marin Engineering Co., Limited, of Wallsend-on-Tyne, are of th triple-expansion type, having cylinders 23½ in., 39 in., and 64 in by 42 in. stroke, and working at a pressure of 160 lbs. O leaving the ways the vessel was named the *Loch Linthrath* by Mrs. Ritchie of Dundee.

West Point.—On March 28th there was launched from th shipyard of Messrs. Robert Stephenson & Co., Limited, a larg steel screw steamer for the Norfolk & North American Stea Shipping Co., Limited, managed by Messrs. Simpson, Spence Young, of London and Newcastle-on-Tyne. The vessel is the following dimensions:—375 ft. between perpendiculars 50 ft. breadth extreme by 30 ft. 1 in. depth, moulded. The ves is built on the three-deck rule to Lloyd's highest class, havi a long bridge, poop, and forecastle. The framing is on the de girder frame system in lieu of hold beams, so as to facilitate stowing of cargo; the main deck is of steel, the upper deck and the bridge and forecastle decks are of iron. There is a cellular double bottom fore and aft for water ballast, a deep ballast tank abaft engine room bulkhead, extending from floors to main deck, also water ballast in after peak. The arrangements for the rapid loading and discharging of cargo are very complete, there being nine powerful steam winches to work the cargo. The vessel is also provided with a powerful steam windlass, a steam steering gear, and a steam warping capstan aft. Under the long bridge there are fittings provided for the carriage of cattle. Accommodation is provided for captain, officers, engineers, and passengers on top of bridge deck amidships, the crew are berthed in poop aft, and the forecastle is fitted up for the accommodation of the cattlemen. Steam heating is provided throughout all the cabin accommodation. The engines are of the triple-expansion type, having cylinders 26 in., 43 in. and 71 in. by 48 in. stroke; steam being supplied by two large multitubular boilers, which will be fitted with Howden's patent system of forced draught, and 180 lbs. steam pressure. A large donkey boiler, 180 lbs. pressure (connected to main boilers), for supplying steam to deck machinery, &c., is placed on upper deck. Both engines and boilers are being constructed by Messrs. Robert Stephenson & Co., Limited, and the whole of the work has been under the supervision of the owners' superintending engineer, Mr. John Baxter, of Newcastle-on-Tyne. On leaving the ways the vessel was gracefully named the *West Point* by Mrs. C. W. Metcalf Dale, wife of the chairman of the Norfolk & North American Steam Shipping Co., Limited.

Jokai.—On March 28th Messrs. R. Craggs & Sons launched at Middlesbrough a steel screw steamer, 351 ft. by 42 ft. 6 in. by 24 ft. 9 in., built to the order of the Royal Hungarian Sea Navigation Co. "Adria," Limited, of Fiume, under special survey and to the highest class 100 A1 at Lloyd's and Austrian Veritas, as a spar-deck vessel with two decks laid, the main deck being of steel and spar deck of checkered iron. The vessel is to be rigged as a two-masted schooner, and is designed to carry a deadweight of about 4,000 tons on a moderate draught. Powerful machinery is being supplied by the North-Eastern Marine Engineering Co., Limited, of Wallsend-on-Tyne, which will be capable of driving the vessel between 10 and 11 knots laden. During the construction of hull and machinery, the work has been under the superintendence of Mr. Alex. Rolland, chief inspector to the owners, and his resident assistant, Mr. Cammera. The vessel was named *Jokai*.

Falaise.—On March 29th the steam yacht *Falaise*, which has been built by Messrs. Day, Summers & Co., of Southampton, to the order of Mr. Forrester Britten, of Shermanbury Grange, Henfield, Sussex, from the designs of Messrs. Thomson & Campbell, of London, was launched at Northam. The principal dimensions of the *Falaise* are as follows:—Length, between perpendiculars, 120 ft. 6 in.; breadth, 18 ft. 6 in.; depth, 12 ft. 3½ in.; tonnage, B.M., 200. The engines are of the compound surface-condensing type, with cylinders 15 in. and 30 in. diameter by 23 in. stroke, steam being supplied by a return-tube boiler 10 ft. 6 in. in diameter by 9 ft. long, having two furnaces, designed for a pressure of 110 lbs. The vessel and machinery have been constructed to Lloyd's highest class.

Milton.—On March 29th this vessel was launched by Messrs. Joseph L. Thompson & Sons, Limited, Sunderland, and has been built to the order of Messrs. Glover Brothers, of London, and is the twenty-fifth vessel ordered by this firm from these builders. She is built on the awning deck rules, her principal dimensions being:—Length, 338 ft.; breadth, 44 ft. 6 in.; and depth, moulded, 22 ft. 2 in. The engines and boilers are being constructed by Messrs. Thomas Richardson & Sons, Limited, of Hartlepool, the sizes of the cylinders being 24 in., 38 in., 64 in. by 42 in. stroke, supplied with steam by two large multitubular boilers working at 160 lbs. pressure.

Novington.—On March 29th Messrs. Richardson, Duck & Co. launched from their yard a steel screw steamer of the following dimensions, viz.:—Length, overall, 323 ft.; breadth, extreme, 44 ft. 6 in.; depth, moulded, 23 ft. 1 in.; gross tonnage about 2,400 tons. This vessel, which has been built to the order of the Southdown Steamship Co., Limited, London (Messrs. Bell, Symondson & Co., managers), will take Lloyd's 100 A1 class, and has been built under special survey. She is of the single-deck type with deep framing, and has poop for captain and officers, bridge over engines and boilers, with engineers' berths in after end, and topgallant forecastle for crew. A cellular double-bottom and after peak tank are fitted for water ballast, and equipment includes four steam winches, large vertical donkey boiler, stockless anchors, steam windlass, steam steering gear, &c. The engines by Messrs. Blair & Co., Limited, have cylinders 23 in., 37½ in., 61½ in. by 39 in. stroke, steam being supplied by two single-ended boilers having a working pressure of 160 lbs. As the vessel left the ways she was christened *Novington* by Miss Edith Bell, of Newcastle-on-Tyne.

King Erik.—On March 29th there was launched at Selby, for the Viking Steam Fishing Co., of Grimsby, an iron steam ketch of about 228 tons gross, named the *King Erik*.

Thordis.—On March 29th there was launched by Messrs. Osbourne, Graham & Co., at Hylton, near Sunderland, a steamer, built to the order of Mr. W. Wilhelmsen, of Tonsberg, Norway. The vessel will take the highest class at Lloyd's, and also at the Norwegian Veritas. Her dimensions are:—Length, 351 ft.; breadth, extreme, 48 ft.; and depth, moulded, 29 ft. She will be fitted with triple-expansion engines by Messrs. Blair & Co., of Stockton, having cylinders of 24 in., 40 in., and 66 in., by 45 in. stroke. The vessel was named *Thordis*.

Viking.—On March 29th there was launched at Hull for Messrs. J. H. Robins & Co., Limited, of Hull, an iron steam ketch of about 182 tons gross, named the *Viking*.

Castro.—On March 30th there was launched at Hull, for Messrs. T. Wilson, Sons & Co., Limited, of Hull, a steel schooner-rigged steamer, of about 1,150 tons gross, named the *Castro*.

Dartmeet.—On March 30th Messrs. R. Craggs & Sons launched at Middlesbrough a fine steel screw raised quarter-deck steamer named *Dartmeet*, 190 ft. between perpendiculars; 30 ft. breadth, extreme; and 15 ft. 11 in. depth moulded; built to the order of Messrs. Whiteway & Ball, shipowners, of Torquay. The steamer will take Lloyd's highest 100 A1 class, and is designed to carry a dead veight of 1,075 tons. The vessel will be provided with machinery supplied by Sir C. Furness, Westgarth & Co., Limited, capable of giving her an average speed of about 10 knots when loaded at sea.

Sangara.—On Saturday April 8th, Messrs. Furness, Withy & Co., Limited, launched from their Middleton Shipyard, Hartlepool, the large steel screw-steamer *Sangara*, built to the order of Messrs. Elder, Dempster & Co., Liverpool. The vessel is a duplicate of the s.s. *Degama*, built by Furness, Withy & Co. for the same owners. She is a fine type of a modern cargo boat, measuring over 350 ft. in length, and built throughout of Siemens-Martin steel to Lloyd's highest class, having large measurement and deadweight carrying capacity. The vessel is of the spar-deck type, with poop, bridge and forecastle, and arrangements fitted for carrying cattle on deck. The holds are fitted with iron grain divisions, and all decks, deck erections, skylights, bulwarks, bulkheads, &c., are constructed of steel and iron. The greater portion of the plates are in 24 ft. lengths, making the structure of the ship very strong. Six powerful steam winches, donkey boiler, patent steam steering gear amidships, screw gear aft, direct steam patent windlass, stockless anchors, and other modern appliances are fitted for the handy working of the ship. The saloon and cabin, which provides accommodation for the captain, etc., is handsomely finished in polished hardwood. The vessel will be rigged as a two-masted fore-and-aft schooner, and has been constructed under the supervision of Captain Evans and Mr. T. Hall. Triple-expansion engines will be fitted by Sir C. Furness, Westgarth & Co., Limited, Middlesbro'.

Archanda.—On Tuesday, April 11th, Messrs. Craig, Taylor and Co., launched a fine steel screw steamer from the new portion of their shipbuilding yard into the new turning berth at Thornaby-on-Tees. The dimensions of the vessel are 299 ft. by 43 ft. by 21 ft. 3 in. moulded. She is of the single deck type, with poop, bridge, and topgallant forecastle, and is built to the highest class in Lloyd's, under special survey. She is fitted throughout with water ballast on the double cellular principle, and is built with deep frames, thus giving clear holds for stowing cargo. She will be fitted with 4 double-powered steam winches, patent steam windlass, patent steam steering gear, large donkey boiler, screw gear aft, telescopic masts, and all modern improvements. Triple-expansion engines have been constructed by Messrs. T. Richardson & Sons, Limited, Hartlepool, the size being 22 in., 35 in., 59 in. by 39 in., with 2 large boilers working at 160 lbs pressure. The vessel has been built to the order of Mr. Felix de Abasolo, of Bilbao, and under the superintendence of Mr. Andres Mendiguren. As the vessel left the ways she was gracefully christened the *Archanda* by Miss Harney, daughter of Captain Harney, of Blyth.

Pomona.—On April 11th Messrs. Cochrane & Cooper, Limited, launched from their Grovehill shipyard, Beverley, a steam trawler of the following dimensions, 106 ft. 4 in by 21 ft. by 11 ft. depth of hold, built to the order of the Hull Steam Fishing & Ice Co., Limited. The vessel was named s.s. *Pomona* by Mrs. Beath, of Hull. Messrs. Amos & Smith are supplying engines of the triple-expansion type, and the vessel will be completed ready for sea with the most modern appliances for trawling.

Milwaukee.—On April 12th an interesting ceremony took place when a large company of visitors assembled at the shipbuilding yard of Messrs. C. S. Swan & Hunter, Limited, to witness the launch of the fore end of the s.s. *Milwaukee*. It will be remembered that the *Milwaukee* (of which we gave full particulars in our columns, December, 1896, page 373; and February, 1897, page 467), a large steamer, 483 ft. long, overall; and 56 ft. beam, owned by Messrs. Elder, Dempster & Co., of Liverpool, when on a voyage from the Tyne to New Orleans, went ashore in Cruden Bay, near Aberdeen, in the month of September last. It was found that a large rock had penetrated the bottom to a height of about 8 ft. above the tank top, and Capt. Batchelor, who had charge of the salvage operations, saw that it was impossible to salve the whole vessel so it was decided to blow her in two with charges of dynamite. This was successfully done, leaving about 180 ft. of the fore end on the rocks, and the after end, with the assistance of tugs, steamed back to the Tyne, where she has been lying waiting for the new fore end which was successfully launched. The old and the new ends will be towed in a few days' time to the dry dock of the Tyne Pontoons & Dry Docks Co., Limited, where they will be joined together.

Warwick.—On Thursday afternoon, April 13th, there was launched from the shipbuilding and repairing works of the Blyth Shipbuilding Co., Limited, of Blyth, a steel screw-steamer, built to the order of Messrs. Atkinson Bros., of Newcastle-on-Tyne. The dimensions of this vessel are:—Length, 243 ft.; breadth, 36½ ft.; depth, 18 ft. 9 in. She is classed 100 A1 at Lloyd's, and is built on the single-deck principle, with poop, bridge, and topgallant forecastle, and has deep frames, but no hold beams. The cabin accommodation is fitted in poop aft, the engineers being berthed under the bridge amidships and the crew in forecastle. Triple-expansion engines will be supplied and fitted by the North-Eastern Marine Engineering Co., Limited, of Wallsend. As the vessel left the ways the ceremony of naming her *Warwick* was gracefully performed by Miss Dolly Cookson, younger daughter of Norman C. Cookson, Esq., of Oakwood. The ship and engines have been built under the inspection of Mr. James Dykes, of Newcastle.

Nunimu.—On Monday, April 24th, Messrs. Wm. Gray & Co., Limited, launched a fine large steel screw steamer to the order of Messrs. Trechmann Bros., of West Hartlepool. She will take the highest class in Lloyd's, and is of the following dimensions, viz.:—Length overall, 341 ft.; breadth, 47 ft.; depth, 27 ft. 4 in., with long bridge, poop, and topgallant forecastle. The saloon, state-rooms, captain's room, &c., will be fitted up in a large deck-house amidships. The officers' and engineers' accommodation will also be on the bridge-deck, and the crew's berths in the forecastle. The hull is built with deep frames, large hatchways are fitted, a large horizontal multitubular donkey boiler, six steam winches with copper exhaust pipes and condenser tank, steam steering gear amidships, hand-screw gear aft and patent direct steam windlass, cellular double bottom and large aft peak tank for water ballast, iron middle line bulkhead to prevent cargo shifting, stockless anchors, telescopic masts with fore-and-aft rig, boats on beams overhead, and all requirements for a first-class cargo steamer. Triple-expansion engines are being supplied by the Central Marine Engine Works of Messrs. Wm. Gray & Co., Limited, having cylinders 25 in., 40 in., and 65 in. diameter, with a piston stroke of 42 in., and large steel boilers for a working pressure of 160 lbs. per square inch. The ceremony of naming the vessel *Nunimu* (after the wife of Dr. Emil Trechmann, Sydney, New South Wales) was gracefully performed by Miss Wanda Trechmann, daughter of Mr. O. K. Trechmann, West Hartlepool.

LAUNCHES—SCOTCH.

Magnific—On March 14th there was launched at Dundee for the Atlantic Steam Fishing Co., of Grimsby, a steel schooner-rigged steamer of about 244 tons, named the *Magnific*.

St. Anthony—On March 22nd there was launched at Greenock, by Messrs. Taylor & Mitchell, a salvage steamer for Mr. J. M'Causland, of Portaferry. The vessel has been constructed with all the latest improvements for salvage work. The engines, which are of the compound type, are being supplied by the owner. The vessel was named *St. Anthony*.

Neptune and **Diana**.—On March 24th Messrs. Mackie & Thomson launched at Govan the steam fishing vessels *Neptune* and *Diana*, which they have built for Mr. W. Widdowson, Hull. Dimensions:—Length, 112 ft.; breadth, 21 ft.; depth, moulded, 12 ft.; tonnage, 180 gross. Triple-expansion engines of 425 I.H.P. will be fitted by Messrs. Muir & Houston.

Seapoint.—On March 25th there was launched from the shipyard of Messrs. S. McKnight & Co., Limited, of Ayr, a fine steel screw cargo steamer of the following dimensions:—Length, 175 ft.; breadth, 26 ft. 6in.; depth, 13 ft. She has been constructed for cargo-carrying purposes for a well-known Irish firm, and is built to the highest class of Lloyd's and up to the most recent modern standard. She is to be fitted with powerful compound surface-condensing machinery by Messrs. McKie & Baxter of Govan. The vessel on leaving the ways was gracefully christened *Seapoint* by Mrs. W. Scott, Bellevue Terrace, Ayr. She will proceed to Glasgow in the course of a day or two to receive her machinery.

Dreadnought and **Defender**.—On March 25th Messrs. Gourlay Brothers launched at Dundee two steel steam trawlers for the Dundee Steam Trawling Co., Limited. The vessels are intended to develop the fishing trade of the port, and were christened *Dreadnought* and *Defender*. The trawlers are built to the highest class at Lloyd's, and under special survey, and the principal dimensions are:—Length, 100 ft.; breadth, 20 ft.; depth, 11 ft.; and gross tonnage, 130 tons. The machinery will be supplied by the builders, and consists of triple-expansion engines.

Dredger.—On March 28th Messrs. Wm. Simons & Co., Limited, Renfrew, launched complete from their yard a powerful barge-loading dredger for the Russian Government. This vessel has been constructed under the inspection of, and is also classed by the Bureau-Veritas. Independent steam hoisting gear is provided for manipulating the bucket ladder, and also independent steam winches are fitted at bow and stern of vessel for manœuvring the vessel when at work. Electric light is fitted on deck and throughout the vessel for working day and night. There are separate cabins for the officers and crew and a private cabin on deck is also provided.

Hortensius.—On March 28th Messrs. Archibald McMillan & Son, Limited, shipbuilders, Dumbarton, launched the steel screw steamer *Hortensius*, building by them to the order of Messrs. R. P. Houston & Co., Liverpool. The dimensions are:—362 ft. by 47 ft. by 27 ft. 6 in., and the gross register is 3,500 tons. A complete shelter deck is fitted over the upper deck, and on top of shelter deck accommodation is provided in large deckhouses for captain, officers, engineers, and a few passengers, while under the deck the crew are accommodated forward, and cattlemen, &c., aft. Three decks will be completely fitted up for cattle, while the water service, condensing apparatus, and ventilation in this connection are of the most perfect description. Water ballast is provided for in cellular double bottom, which is subdivided, so as to give storage room for fresh water for cattle and boilers. All latest improvements have been introduced for the speedy loading and discharging of cargo, and altogether the vessel will be fitted out in a very superior manner. The engines are triple-expansion, having cylinders 26 in., 43½ in., 72½ in. by 48 in. stroke, with three large single-ended boilers. The vessel is intended for the River Plate service, with which the owners have had long connection, and as Mr. Houston has designed the vessel to meet the special requirements of this trade, the *Hortensius* should prove a valuable addition to the fleet of vessels already in Messrs. Houston's service. The vessel and machinery have been built to Lloyd's highest class, and under the supervision of Mr. William McLaren and Captain Hopkins, the company's superintendents. The christening ceremony was gracefully performed by Mrs. William McLaren, Rock Park, Rock Ferry, Birkenhead.

Upada.—On March 28th Messrs. A. & J. Inglis launched from Pointhouse yard, on the Clyde, a screw-steamer for the British India Steam Navigation Co. of 5,600 tons gross and 2,300 I.H.P. The vessel, which was named the *Upada*, will be employed in the Indian coasting trade.

Zealandia.—On March 29th Messrs. Gourlay, Brothers & Co. launched at Dundee a steel screw passenger steamer for Messrs. Huddart, Parker & Co., Limited, Melbourne. The vessel, which was named *Zealandia*, is intended for passenger and cargo traffic between the principal ports of Victoria, New South Wales, New Zealand, &c. Her principal dimensions are :—Length, 327 ft. ; breadth, 42 ft. ; depth, 23 ft. ; with a gross tonnage of 2,900.

Rembrandt.—On March 29th there was launched from the shipbuilding yard of Messrs. David & Wm. Henderson & Co., Partick, a very complete steel screw cattle steamer, which they have built to the order of Messrs. Lamport & Holt, Liverpool, for their South American trade. The vessel—which is 394 ft. over all, by 50 ft. broad, and 30 ft 6 in. depth, to carry 6,550 tons deadweight on British Corporation summer freeboard—has been constructed under special survey to class B S in British Corporation registry of shipping. The vessel is built with a shade deck right fore and aft, on which it is intended to carry sheep; whilst the main deck will be fitted up for carrying cattle, to which special attention has been given, and the most approved modern appliances in this connection fitted. The cattle fittings are adjustable, and can be quickly removed if necessary. In regard to the ventilation of the cattle space, every care has been taken. In addition to the very large number of natural draught ventilators, there are two specially designed ones, placed amidships, and each fitted with powerful steam driven fans to circulate the air. Between the top of the main deck bulwark and the shade deck there is an opening two to three feet wide, and extending a considerable distance forward and aft of the amidships portion of the ship; through the openings, in conjunction with the ventilators, an ample supply of fresh air is always obtainable, and in bad weather these openings can be planked in, thus practically enclosing the whole of the main deck. A very efficient fresh water service is provided both above and below. The ship has a cellular double bottom right fore and aft for water ballast, the portion under the engines and boilers being set aside for fresh water in view of the large number of cattle the vessel will at times be carrying. The fore and aft peaks are also arranged for use as trimming tanks. The vessel has also been provided with seven powerful steam winches and derricks, to facilitate the rapid handling of the large cargo which, in addition to the cattle, she has been designed to carry. Quarter pillars have been dispensed with in the principal holds and 'tween decks, thus ensuring ample clear space for stowing bulky cargo. Steam steering gear by Messrs. Bow, MacLachlan & Co. has been fitted amidships, and also hand steering gear by the builders aft; steam capstan windlass forward by Messrs. Emerson, Walker & Thompson Bros., and a very complete installation of electric light supplied and fitted by Messrs. W. C. Martin & Co. Houses have been fitted on the shade deck amidships for the accommodation of the officers and engineers, with saloon, steel specie-room, bath-rooms, &c. The saloon is neatly and tastefully fitted up in polished oak with upholstery of colour to match the same; on top of the saloon house there is a teak-house for captain, chart-room, and wheel-house. The seamen, firemen, and petty officers are berthed forward under the shade deck, whilst the necessary accommodation for the cattlemen has been arranged at the after-end, also under the shade deck. A complete system of steam heating has been fitted in all living accommodation. The vessel will be rigged as a two-masted fore-and-aft schooner, having steel lower masts and telescopic wood topmasts to suit Manchester Canal. A set of triple-expansion engines, with cylinders 27½ in., 46 in. and 74 in. by 48 in. stroke, and three single-ended boilers constructed for a working pressure of 180 lbs., have been supplied and fitted by the builders, the boilers being of extra large size and arranged for Howden's forced draught system. In designing this steamer, every possible advantage has been taken of the vast experience of the owners for their special trade, and therefore both ship and machinery have been fitted throughout with the most recent improvements for a thoroughly up-to-date first-class cattle and cargo steamer. The vessel will form a valuable addition to the already large fleet of steamers employed by the owners in their extensive trade to South American ports, and is a sister ship to the s.s. *Raphael* lately completed bv the builders for Messrs. Lamport & Holt. During construction, the hull has been built under the supervision of Mr. John Russell, and the machinery under that of Mr. Morrin and Mr. Fred Thompson. On leaving the ways the vessel was gracefully named *Rembrandt* by Mrs. Herbert Pilkington, of Wheathill, Huyton, Lancashire.

Upnor, H.M.S.—On March 30th Messrs. J. M'Arthur & Co., Paisley, launched from their shipyard H.M.S. *Upnor*, a steel single-screw steamer of about 500 tons gross. The *Upnor*, which has been built throughout to Admiralty requirements and under Admiralty supervision, is to be engaged as a store-carrying vessel for the Naval Ordnance Department. The vessel is built with raised quarter-deck, raised forecastle, and has propelling machinery close aft, in order to give one long clear hold and one long loading hatch. Pillars in hold are dispensed with thus giving ample and free uninterrupted space for stowing heavy guns or other bulky loads. The *Upnor* is fitted with a complete equipment to make the vessel thoroughly suitable for the purposes she has been designed and built for. The engines, which are of the compound surface-condensing type with all latest improvements, are being supplied and fitted by Messrs. Bow, M'Lachlan & Co., Thistle Works, Paisley. On leaving the ways the vessel was named by Miss Bow, Dunscore, Paisley.

Angele Achaque and **Carmel** and **Charles Achaque.**—On April 1st Messrs. John Shearer & Son launched at Kelvinhaugh, the steamers *Angele Achaque* and *Carmel* and *Charles Achaque*. The vessel were built to the order of Messrs. Paton Hendry, Glasgow, to plans prepared by James Donaldson, C.E., and under his supervision. They are exceptionally strong and well equipped, having been built in excess of Lloyd's 100 A1 requirements to permit of loading and discharging on the ground. Powerful compound surface-condensing engines to drive the steamers at a high speed are being fitted by Messrs. Muir & Houston, Limited. After trials the vessel will leave the Clyde for Algiers, where they will be engaged in the Algerian coasting service of Messrs. Achaque, Algiers, to whom they have been sold by Messrs. Paton & Hendry.

Lucy.—On April 1st Messrs. Scott & Sons launched at Bowling a screw steamer which they have built to the order of Messrs. Joseph Monks & Co., Limited, Warrington. Dimensions :—Length, 90 ft. ; breadth, 20 ft. 6 in. ; and depth, moulded, 10 ft. The vessel is to be fitted with compound surface-condensing engines by Messrs. Fisher & Co., Paisley. She was named *Lucy* by Mrs. Joseph Monks, jun., Warrington.

Lincolnshire.—On April 3rd Messrs. Russell & Co. launched from Kingston Yard, Port-Glasgow, the steel screw spar-decked steamer *Lincolnshire*, for Messrs. J. & A. Roxburgh, Glasgow. The steamer measures :—Length, 345 ft. ; breadth, 49 ft. 9 in. ; depth, 28 ft. 6 in. moulded. The deadweight carrying capacity on Lloyd's summer freeboard is 6,400 tons. Messrs. Rankin & Blackmore, Greenock, will supply triple-expansion engines of 25 in., 41 in., and 67 by 45 in. stroke.

Renown.—On April 8th Mr. James Miller launched at St. Monans a first-class fishing boat, 69 ft. in length, with a breadth of beam 21 ft. 6 in , built to the order of Mr. Andrew Scott, of that port. The boat was named the *Renown*.

Irene.—On April 10th the Grangemouth Dockyard Co. launched from their yard at Grangemouth the steel screw steamer *Irene*, built to the order of Messrs. Furness, Withy & Co., of West Hartlepool, for Mr. C. Hulthen, of Helsingborg. This vessel is a duplicate order to the s.s. *Muriel*, built last year by the Grangemouth Dockyard Co., for Messrs. Furness, Withy & Co., and is fitted up with all modern appliances for a cargo vessel with a view principally to the carriage of grain and wood cargoes, comprising grain shifting boards and ventilators, deck arrangements for wood cargoes, large water ballast capacity, steam steering gear, quick warping steam windlass, and steam warping capstan. Her dimensions are: 270 ft. by 40 ft. 6 in. by 20 ft. 6 in., and she is built on the bulb frame principle with single deck, poop, bridge, and forecastle. She will carry a total weight of 3,100 tons with Lloyd's summer freeboard, and has a low net tonnage. The engines are triple-expansion, having cylinders 20 in., 32½ in., and 53 in. by 36 in. stroke, and steam will be supplied by two large single-ended boilers working at a pressure of 160 lbs. The donkey boiler is of Blake's patent type. The construction of the vessel has been superintended on behalf of Messrs. Furness, Withy & Co. by Mr. A. Walker, shipbuilding superintendent, and on behalf of Mr. Hulthen, by Captain Borjessen, assisted by Mr. James Donaldson, consulting engineer, of Glasgow, who has also superintended the construction of the machinery. On leaving her building berth the ceremony of naming the vessel was gracefully performed by Mrs. Harvey, of Prospect House, Polmont. The Grangemouth Dockyard Co. are at present exceedingly busy, having seven vessels on hand, two of these being large steamers fitted for carriage of oil in bulk.

Salamis.—There was launched on April 11th from the shipbuilding yard of Messrs. Hall, Russell & Co. Limited, Aberdeen, a large steel screw-steamer, built to the order of Messrs. George Thompson & Co., of Aberdeen and London, for their service between London and Australia. The vessel is the largest by 1,000 tons ever set afloat at Aberdeen. Her dimensions are:—Length over all, 412 ft.; breadth, 47 ft.; depth, 32 ft. 3 in. She is 4,700 tons register, and has engines of 4,300 I.H.P. The hull and machinery have been built under special survey to class 100 A1 at Lloyd's, and with all the most modern requirements to pass the Board of Trade for a passenger certificate. The vessel has been constructed on the spar-deck principle, having three complete steel decks, full poop, bridge-deck and topgallant-forecastle, and above the bridge-deck a shelter-deck is fitted, on which the boats are placed, and at the fore-end a navigating bridge. Water ballast tanks are fitted amidships in cellular double-bottom and in afterpeak. On leaving the ways the ceremony of christening the steamer *Salamis* was gracefully performed by Mrs. George T. Henderson, London. The *Salamis* will be commanded by Captain A. H. Douglas, R.N.R., formerly of the s.s. *Damascus*, of the same line.

Ziska.—On April 11th the Ailsa Shipbuilding Co. launched at Troon a steel screw steam yacht, designed by Mr. A. Richardson, of Liverpool, for Mr. S. T. Chadwick, of Haulfre, Anglesey. The dimensions are:—Length on load water-line, 101 ft. 8 in.; breadth, moulded, 18 ft. 6 in.; depth, moulded, 11 ft. 6 in. The machinery, which is of the triple-expansion type, is being fitted by Messrs. Muir & Houston, Limited, of Kinning Park Works, Glasgow. On leaving the ways the yacht was named *Ziska* by Mrs. Chadwick.

Ismore.—On April 12th there was launched from the shipbuilding yard of Messrs. Barclay, Curle & Co., Limited, Clydeholm, Glasgow, a steel screw-steamer, built to the order of Messrs. Edward Bates & Sons, Liverpool. The vessel is classed at Lloyd's 100 A1 on the three-deck rule, with additional extra strengthening for trading in the North Atlantic, and has continuous shelter-deck all fore and aft, on which cattle fittings are fitted up complete in the most approved modern style. The vessel has a deep tank placed aft for trimming when light, and is fitted with all the best appliances for the working of ship and cargo. While under construction the ship and machinery were under the supervision of Messrs. Clark & Garrick. Her moulded dimensions are 452 ft. by 53 ft. 3 in. by 34 ft. 1 in., and measures about 6,200 tons gross. On leaving the ways the vessel was named *Ismore* by Mrs. Maclean, Ardgour, Balshagray Avenue, Partick, and was afterwards towed to the harbour to receive her machinery, which is being supplied by the builders.

Cork.—On April 12th Messrs. Blackwood & Gordon launched at Port-Glasgow a steel screw-steamer, to the order of the City of Dublin Steam Packet Co., of Dublin, to be employed in the cross-channel trade between Dublin and Liverpool, as consort to the four popular steamers, *Louth*, *Wicklow*, *Carlow*, and *Kerry*, which steamers were also built by Messrs. Blackwood & Gordon. The steamer on leaving the ways was named the *Cork* by Mrs. D. B. M'Geoch, wife of the senior partner of the builders' firm, and was afterwards placed in the builders' wet dock, alongside of their works, to receive her machinery and boilers, which have also been constructed by the builders. The dimensions of the *Cork* are as follows:—Length, 260 ft.; breadth, 34 ft.; depth, 16 ft. 9 in.; having also a long poop, bridge and forecastle, with short breaks filled in, and a gross tonnage of about 1,300 tons. The hull is constructed of heavy scantlings very much in excess of the requirements of Lloyd's class, and of full lines, suitable for the cross-channel trade in all sorts of weather. She is fitted with Harrison's patent steam-steering gear. Wilson's patent steam windlass forward, and their patent steam capstan aft; also one powerful steam crane and steam winch, also of Wilson's make. Suitable cattle fittings for fully 500 cattle are placed in the holds, 'tween and main decks, and efficient mechanical ventilation with large ventilators will be provided, so as to ensure the safe and comfortable conveyance of live stock, special attention having been given to this very important question by the builders, acting on the instructions of the managing directors, who by their long experience of shipping matters are thoroughly conversant with all the newest requirements of vessels engaged in the cattle trade. Accommodation for 150 first-class passengers in all has been provided in cabins on bridge-deck, also in cabins in large house on poop-deck, and in main saloon under poop-deck. A comfortable and well-ventilated cabin has been fitted up for the exclusive use of cattle dealers, and also a large and airy steerage has been arranged forward for third-class passengers, separate apartments being provided for male and female passengers. Electric light, by Siemens Brothers, is being fitted up in all the holds, engine and boiler-rooms, and in all parts of the accommodation. A comfortable smoking-room is placed on bridge-deck amidships, and the captain and chief officers are located in a teak deckhouse placed above the smoking-room, from which they have easy access to the flying bridge, which is placed above their rooms. Water ballast tanks are fitted in fore and after holds with special pumps for filling and emptying quickly. The engines are of the triple-expansion type, of fully 3,000 H.P., with all the latest improvements, including bronze propeller, and are supplied with steam from two large double-ended boilers, working up to 170 lbs. pressure. The *Cork* is built on similar lines to the former steamers, but with the improvement that she has accommodation for 50 additional first-class passengers over *Carlow* and *Kerry*, placed in private cabins amidships, and has also a larger smoking-room. During construction she has been under the supervision of Mr. Edwin G. Ferber, the engineering superintendent of the City of Dublin Co. Among those present were:—Captain George R. Bell and Mrs. Bell, Liverpool; Mr. E. G. Ferber, engineering superintendent of the company; Mr. and Mrs. D. B. M'Geoch, Mr. F. P. Purvis, Mr. and Mrs. J. H. M'Alpine, Miss M'Geoch, Paisley; Mr. George Gow, New Zealand; Mr. H. H. Broadley, East Yorkshire; Mr. William Baird, Mr. G. A. Fullarton, &c. After luncheon, Mr. M'Geoch proposed "Success to the steamer *Cork* and her owners." He said this was the sixth steamer his firm had built for this old-established and well-known Irish company. All her predecessors had proved themselves efficient and satisfactory to the cattle-dealers and the travelling public, and he had no doubt the *Cork* would maintain the prestige of the company in the safe and efficient service they had so long conducted between Dublin and Liverpool. Captain Bell, R.N., marine superintendent of the company at Liverpool, replying, said this new steamer was of a similar type to those they had already seen launched by Messrs. Blackwood & Gordon, and which had been the means of greatly strengthening the company. It was a very expensive matter to keep pace with the times, but they had to do it or be left behind. The former steamers had all proved successful vessels to the company, and he felt quite sure the *Cork* would give every satisfaction. Mr. Bell then proposed the health of Mrs. M'Geoch, the lady who named the steamer, and Mr. M'Geoch replied. Mr. Broadley submitted the toast of "The Builders," and Mr. F. P. Purvis responded.

Burton-Port.—On April 14th Messrs. John Fullerton & Co. launched at Paisley a steel screw-steamer of about 300 tons, which has been built to the order of Mr. John Herdman, Carricklee, Strabane, for his local and Channel trade, and for which the steamer has been specially designed and equipped, being fitted with steam-steering gear, electric light, &c. Compound engines of 350 H.P. are being supplied by Messrs. Muir & Houston, Limited, Glasgow. The steamer was named *Burton-Port*, by Mrs. Buchanan, Redhurst, Bridge of Weir.

Clan Maclaren.—On April 24th the sixteenth steamer built by Messrs. Alex. Stephen & Sons for the Clan Line was launched at Linthouse, and was named the *Clan Maclaren* by Mrs. John F. Maclaren, of Merrylee, Cathcart. The dimensions of the vessel—which is a duplicate of the *Clan Macaulay*, recently launched by the same firm - are 326 ft. by 40 ft. 3 in. by 26 ft. 2 in., and she is built under special survey to the 100 A1 three-deck-rule of Lloyd's. The cylinders are 23 in., 38 in., and 63 in. diameter, with a stroke of 43 in ; and the boilers, which are adapted for 800 lbs. working pressure, are fitted with Howden's forced draught. The vessel in design, fittings, and appliances is of the most modern and approved description. Messrs. Stephen have another steamer in hand for the Clan Line.

LAUNCH—Irish.

Ping Suey.—On March 30th, at high water, Messrs. Workman, Clark & Co., Limited, Belfast, launched from their north shipyard a large steel screw-steamer, named the *Ping Suey*, designed to suit the Eastern trade carried on by the China Mutual Steam Navigation Co , of London. The dimensions are:—Length, 450 ft.; breadth, 53 ft.; depth moulded, 33 ft. 11 in.; with a gross tonnage of 6,457 tons, deadweight capacity 9,200 tons. After the launch a tug conveyed the owners and friends on board the *Yangtsze*, a sister ship of the *Ping Suey*, which, earlier in the morning, had proceeded down Belfast Lough. This vessel has been built for the same owners under Lloyd's special survey for the 100 A1 class, and is provided with a Board of Trade passenger certificate. The machinery, which has been constructed at the builders' engine works, consists of triple-expansion engines and two large steel boilers fitted with Howden's system of forced draught.

TRIAL TRIPS.

Moorabool.—On March 24th the screw-steamer *Moorabool*, built by the Blyth Shipbuilding Co., Limited, for Messrs. Huddart Parker & Co., Limited, of Melbourne, was taken to sea for her trial trip. The dimensions of the vessel are:—Length, 337 ft.; breadth, 47 ft.; depth, 24 ft. 10 in. She has been built to Lloyd's highest class and is fitted with all the latest appliances for quick discharging of cargo; has Emerson Walker's patent windlass, four of Clarke Chapman's winches, and four friction winches by Messrs. J. Lynn & Co., of Sunderland. Messrs. Blair & Co., Limited, of Stockton, have supplied the engines, which are of the triple-expansion type having cylinders 24 in., 40 in. and 65 in. by 42 in.-stroke, to Lloyd's and Board of Trade regulations. Notwithstanding the heavy sea running the performances of both ship and machinery were in every way highly satisfactory. During construction the hull and engines have been under the superintendence of Mr. W. Cumming, the owners' engineer. After trial the vessel proceeded to London, under the command of Captain W. Laws, where she will load a general cargo for Melbourne.

Bethania.—On March 25th the s.s. *Bethania*, the second of two steamers built and engined by Messrs. Alex. Stephen & Sons, Linthouse, Glasgow, to the order of Sir Christopher Furness for the Hamburg-America Co., Hamburg (of which we gave full particulars in our columns, February issue, page 473), ran her trial trip in the Firth. The machinery consists of a set of triple-expansion, surface-condensing engines. Steam is supplied by four large boilers having 18 furnaces in all, and working at a pressure of 180 lbs. per square inch. The boilers are constructed under the rules of Lloyd's, Board of Trade and the Hamburg Police Building Board. The engine room contains a number of auxiliary engines, such as two Weir's feed pumps; centrifugal circulating pump by Drysdale & Co.; two service duplex pumps—Worthington Admiralty pattern; duplex pump for pumping fresh water to cattle; also Quiggin's combined evaporator and winch condenser. A large pulsometer is fitted as a ballast pump. The propeller blades are of Parson's manganese bronze. For discharging cargo fourteen powerful winches are fitted on deck, one main boiler being used as an auxiliary boiler in port. The steam and hand steering gear and patent rudder brake are by John Hastie & Co., Greenock, who also constructed the Wilson & Pirrie patent elastic quadrant. Mr. Blumenthal represented the Hamburg-America Co. at the trial, which was a highly satisfactory one in every respect. The *Bethania* and her sister ship, the *Bengalia*, have been completed under the superintendence of Mr. van der Smissen, assisted by Mr. Brandt. She is commanded by Captain Pietsch.

Saint Andrew.—On March 25th, the twin-screw-steamer *Saint Andrew*, which has been built for Messrs. Rankin, Gilmour & Co., of Liverpool, by C. S. Swan & Hunter, Limited, Wallsend (of which we gave full particulars in our Launch columns, February issue, page 475), was taken out to sea on her trial trip. The vessel will carry a dead-weight cargo of about 10,700 tons, and a measurement cargo of 18,000 tons. On the trial everything worked with perfect smoothness, and a mean speed of over 14 knots was obtained by the log, the mile posts being invisible owing to fog. The vessel and her engines have been built under the supervision of Captain Davey and Mr. Reid, the marine superintendent and superintendent-engineer, for the owners, who expressed themselves highly satisfied with the way everything worked.

Wandby.—On Saturday, March 25th, the s.s. *Wandby*, built by Messrs. Ropner & Son, of Stockton-on-Tees, to the order of Messrs. R. Ropner & Co., West Hartlepool (of which we gave full particulars in our Launch columns, April issue, page 40), made her official trial trip in the Tees Bay. The engines are supplied by the well-known firm of Messrs. Blair & Co., Limited, Stockton, the power of same being 1,250 I.H.P. The trial trip was quite satisfactory in every respect, the steamer attaining a speed of 11 knots between the Tees and the Tyne. The owners were represented by Mr. Rooke, one of their superintendents, and the builders by Mr. Leonard Ropner.

Gwynwood.—On March 29th the new steel screw-steamer *Gwynwood*, built by Messrs. William Dobson & Co., Low Walker-on-Tyne, to the order of Messrs. H. C. Pelly & Co., of London, was taken to sea for her trial trip. The dimensions of the vessel are:—Length, 212 ft.; breadth, 35 ft.; depth, moulded, 16 ft. 5 in. The machinery, which has been constructed by the North-Eastern Marine Engineering Co., Limited, is of the triple-expansion type, having cylinders 18½ in., 30 in. and 49 in. diameter, by 33-in. stroke, steam being supplied by one large boiler working at 160 lbs. pressure. The working of the machinery during the trip was all that could be desired.

Windsor Castle.—On March 31st the steam trawler, *Windsor Castle*, built by Messrs. Cochrane & Cooper, Beverley, in the yard at Govan, (of which we gave full particulars in our Launch columns, March issue, page 516) went down the Clyde on a trial trip. The trial was in every way satisfactory, a speed of 11 knots being attained.

Clan Macaulay.—On April 1st, the fine steel screw-steamer *Clan Macaulay* proceeded down the river on her trial trip. This is the fifteenth vessel which Messrs Alex. Stephen & Sons have constructed for the Clan Line (of which we gave full particulars in our Launch columns, April issue, page 42). On a mean of two runs over the measured mile the speed attained was 12·29 knots, the ship being within a few inches of her load line. The machinery worked with perfect smoothness, and the owners, represented by Mr. Gibb and Mr. Lyall, expressed themselves as highly pleased with the vessel's performance.

Mundaka.—On April 5th, the fine steel screw-steamer *Mundaka* (of which we gave full particulars in our Launch columns, March issue, page 512), was taken out from the yard of Messrs. Wm. Gray & Co., Limited, West Hartlepool, for her trial trip. She has been built to the order of Senor Ramon de la Sota, of Bilbao, and is the fifth vessel built by Messrs. Gray for the same gentleman. Several runs were made along the coast, with very satisfactory results, the vessel on the conclusion of the trial at once proceeding to Bilbao for her first cargo.

Peareth.—On Thursday morning, April 6th, the large steel screw-steamer *Peareth*, built by Messrs. Irvine's Shipbuilding and Dry Docks Co., Limited, West Hartlepool (of which we gave full particulars in our Launch columns, April issue, page 41), was taken out to sea for her official trials under the command of Captain McKenzie. After the vessel's compasses were adjusted her head was turned seawards, when she made several runs. The speed obtained and the vessel's performance generally was the comment of all on board, the owners expressing great satisfaction.

Pauline.—On April 11th the new steam trawler *Pauline* was taken on her trial trip, which was in every way successful, the vessel steaming 11 knots, and the engines working smoothly throughout. The *Pauline* has been built by Messrs. Eltringham & Co., of South Shields, to the order of the Wear Steam Fishing Co., Limited, of Sunderland. She is to be engaged exclusively in the development of the Sunderland fish trade. The vessel is built of steel to class 100 A1 at Lloyd's. Her dimensions are 96 ft. by 19 ft. by 11 ft. 6 in. Her engines are on the compound surface-condensing principle.

Jabiru.—On April 13th the s.s. *Jabiru*, which has been built by Messrs. Wigham, Richardson & Co , at their Neptune Works, Newcastle-on-Tyne, to the order of the Cork Steamship Co., Limited, of Cork, for their Continental service, sailed from the Tyne. During the day the steamer was at sea, but owing to the bad weather no speed trials could be made, but the machinery worked during the whole time in a manner which gave satis faction to all concerned. The vessel is 260 ft. long by 34½ ft. beam; she is built to attain the highest class in Lloyd's Register, and is fitted with triple-expansion engines. She has also very comfortable accommodation for a limited number of first-class passengers, and is supplied with all the most improved appliances both for handling the ship herself and her cargo. The owners were represented on the trial trip by Capt. Hore, of Liverpool, their marine superintendent, and Mr. J. A. Flockhart, of Liverpool, their superintendent engineer, whilst Captain Dobson took command of the ship on her first voyage. This steamer is the fourth built for the Cork Steamship Co., by Messrs. Wigham, Richardson & Co., and there are two more in hand.

Birker Force.—On April 13th the trial trip of the s.s. *Birker Force* took place, and proved highly satisfactory, a speed of 10½ knots being attained. This vessel was recently launched by the Irvine Shipbuilding and Engineering Co., Limited, Irvine, for the Birker Force Steamship Co., Limited, Whitehaven (of which we gave full particulars in our launch columns, April issue, page 43), and is specially fitted for their coasting and Continental trade.

Claudius.—On April 20th the fine large screw-steamer *Claudius*, built by Messrs. Wm. Gray & Co., Limited, of West Hartlepool, to the order of Mr. C. Andersen, of Hamburg (of which we gave full particulars in our Launch columns, April issue, page 42, and August issue, page 208), was taken to sea for her trial trip. The engines have been supplied by the Central Marine Engine Works of the firm, and have cylinders 25½ in., 40½ in., and 67 in. in diameter by 45 in. stroke. The boilers are three in number, 13 ft. 3 in. diameter by 10 ft. 6 in. long, and work at a pressure of 170 lbs. per square inch. Manganese bronze blades are fitted, a Mudd's evaporator, &c., and the vessel is lighted throughout with electricity. After adjustment of compasses, the vessel and her machinery were put under the usual tests, with very satisfactory results, there being no hitch whatever. The average speed recorded was 11¾ knots.

Hyanthes.—Lately the steamer *Hyanthes*, built by Messrs. Bartram & Sons, Sunderland, for Messrs. R. P. Houston & Co., of Liverpool (of which we gave full particulars in our launch columns, March issue, page 513), has had a very successful trial trip. The vessel is replete with everything that experience can suggest for the safe carrying of cattle as well as general cargo. Cattle stalls of a modern and improved type for about 600 head of cattle are fitted in the 'tween decks, and on the shelter deck, which runs right fore and aft, a very large number of sheep are arranged for. Several high-speed engines and centrifugal fans provide a very extensive system of ventilation throughout the vessel. After the completion of the trial the vessel proceeded to her berth at Glasgow to load cargo for the River Plate.

Rhodesia.—Lately the large steel screw steamer, *Rhodesia* (of which we gave full particulars in our Launch columns, April issue, page 41), left the Wear for her trial trip. She has been built by Messrs. John Priestman & Co., Southwick, to the order of Messrs. John Cory & Co., Cardiff. A heavy sea was running at the time of the trial, but the vessel behaved splendidly, everything working to the satisfaction of all on board. After the trial the vessel went into Blyth to take her first cargo.

Eastern.—Lately the new steamer *Eastern*, built by R. Napier & Sons, Limited, Govan, for the Eastern and Australian Steamship Co., London (of which we gave full particulars in our Launch columns, March issue, page 515), has completed her official trials on the Firth of Clyde, when all the conditions of the contract were fully complied with. The machinery consists of a set of triple-expansion engines, having cylinders 27 in., 45 in., and 73 in. diameter by 4 ft. stroke, with two double-ended boilers for a working pressure of 185 lbs., and fitted with the most recent appliances for efficiency and economy, including Howden's forced draught, bronze propeller blades, &c. The results of the trials were very satisfactory, the contract speed being easily attained, and Mr. Henry Stubbings, who represented the company, expressed himself as highly pleased with the ship and her performance.

M. A. Hanna—On March 29th, the Globe Shipbuilding Co., Cleveland, Ohio, launched the steel propeller, *M. A. Hanna*, *430 ft. long overall.*

Reviews.

Engine-room Practice. By John G. Liversedge, Chief Engineer. R.N. London: Charles Griffin & Co., 1899.

The author of the present volume has designed his work to form, as it were, a counterpart and supplement to that well-known and most useful book, Seaton's "Manual of Marine Engineering." That is to say, he endeavours to avoid treating here of matters with which Mr. Seaton deals, so that there may be as little as possible overlapping between the two books. A general description of the machinery of steam ships is afforded, both main and auxiliary engines being dealt with. An excellent notion of the arrangement of the machinery of a modern vessel is given by illustrations of the engine-room of H.M.S. *Powerful*, one of the two biggest cruisers in her Majesty's Navy. For a list of the numerous auxiliary engines now found aboard steam vessels he gives details of the installations fitted in H.M.S. *Prince George*, a recently commissioned battleship of the first class. This gives an excellent index of the responsibilities of the engineering department in modern days. Then a chapter is devoted to a statement of the conditions of service of engineer officers in the Royal Navy and in the Royal Naval Reserve. Here there are many useful, practical hints which we have never previously seen in print. The same remark applies to the matter of the next chapter, where the treatment just given to the Queen's service is applied to that of leading companies under the Red Ensign. Here special information as to the procedure in the P. & O. fleet is afforded. Information as to the various duties in the engine and boiler rooms, from the time steam has to be raised till the vessel is at her destination and minor repairs have to be effected; the best modes of adjusting machinery at sea and of dealing with breakdowns; the treatment of boilers and of auxiliary machinery; the mode of dealing with the under-water fittings, and with the parts of the hull with which the engineer is concerned, are discussed. A good deal of detail applicable only to the work of naval engineers is afforded. Amongst this may be cited the account of the Temperley Transporter—which is only used (so far as we know) in practice for the coaling of warships at sea—the care of the engines and boilers of small steamboats (which are seldom seen in merchant ships), the air-compressing machinery—which is used only for charging torpedoes—and the management of torpedo-boat destroyers' machinery. But on the other hand there is a good deal of attention paid to the proper management of refrigerating machinery, which as yet is not largely introduced into Queen's ships, though its use there is likely in the future to be greatly extended.

We have very briefly indicated the ground covered by Mr. Liversedge's book. But we have said enough to show that it will be invaluable to the young engineer who wishes to thoroughly understand and efficiently fulfil his duty at sea. It is certainly well up to date, and will be a very valuable memorial in years to come of the position of the marine engineer and the level of his profession at the close of the nineteenth century.

A Practical Dictionary of Electrical Engineering and Chemistry in German, English and Spanish. By Paul Heyne. Dresden: Gerhard Kuhtmann; London: H. Grevel. 1899.

This work is published in three volumes, of which the one before us is the second. The plan of the work is to give in parallel columns words and phrases in the three languages dealt with. Each of the three volumes therefore begins with a different language in the first column, which is the one that gives the alphabetical sequence. That with which we are favoured shows English in the index column, followed by Spanish and German. The work seems thorough and is likely to be of use to engineers and chemists and those who write on the subjects affected. For it is certain that little attention has been given to the provision of works of this character dealing with the Spanish language, though that tongue is so largely spoken by many nations in extra-European countries. There need be no apology for adding the German column, since Germany is nowadays so advanced in all that concerns practical science. The work seems to embrace a very large number of words, and special attention has been given to the rendering of compound words and phrases, which are each set under their catch words. We may certainly recommend the book to those who have business dealings and correspondence with Spanish or German firms.

Water-tube Boilers in the German Navy.—A German engineer, writing on the subject of the systematic trial being given to the several systems of water-tube boilers in the German Navy, observes that it is premature as yet to pass positive judgment upon any one of them, but as far as the experiments have gone the following results may be noted. First of all as to the Thornycroft system. This has been applied to the coasting ironclad *Aegir*, which has been making trial trips for fully half a year and has further taken part in the autumn manœuvres, and the system has come out very well under the test. For instance, it has been shown that with the engineering staff working at forced pressure, it is possible to get up steam in at least 25 minutes—a very remarkable achievement, which quite puts the locomotive and other boilers of that type into the shade. Also, the trial has shown many apprehensions which were expressed as to the advisability of adopting the Thornycroft boiler to be groundless. Particularly striking is the saving in weight of this system in comparison with that of the locomotive boiler system on the sister ironclad, the *Odin*. The total weight of the boilers on the latter stands at 105 tons, as against 68 tons on the *Aegir*, while the weight of the *Odin's* boilers, ready for use, is 239 tons, as compared with only 190 tons on the *Aegir*, and the *Odin* again has to carry 49 tons of water in her boilers, whereas 23 suffices for the *Aegir*. These proportions are still more striking in the case of the new ships of the line and the cruisers. On the former the saving of weight effected by the employment of one-third water-tube boilers amounts to 140 tons, and where these boilers have been wholly adopted on the large cruisers the saving is as much as some 280 tons. The reason, the writer remarks, why the tubular boilers have only been partially adopted on the new ships of the line, as in the case of the *Fürst Bismarck*, is that the heavy battleships as a rule only travel at a reduced speed, for which the one-third tubular boilers would be quite sufficient in the very shortest time to develop the required propelling power. The German system of tubular boilers, that of Durr, has also given satisfactory results as far as the trial trips of the *Baden*, *Baiern*, and *Victoria Luise* have shown, and if certain improvements in it which have been taken in hand are succeeded with, then, it is declared, its future will be assured. Others of the fleet equipped after this system of boiler are the big cruiser *Vineta*, and the ship of the line *Sachsen*. The Belleville system has so far only been tried on the two big cruisers *Hertha* and *Hansa*. This class boiler is somewhat heavier than the Durr, and entails a bigger consumption of coal. The *Hertha*, which is the biggest cruiser fitted up on the Belleville system, developed on her trial trip 10,173 H.P., while the *Freya*, with the Niclausse boiler, developed 10,226 H.P., and the *Victoria Luise*, with Durr boilers, 10,863 H.P. Further trial trips, which are to be made during the summer, are expected to give more definite results.

The Marine Engineer.

LONDON, JUNE 1, 1899.

WE have before us a terse but very emphatic statement of the present disabilities and unjust disadvantages meted out to the engineering branch of the Royal Navy. These disadvantages, and causes of dissatisfaction are, briefly, that engineer officers are still classed as a civil branch of the Navy. They have no executive control in their own department, cannot award even minor punishments, and cannot sit on courts-martial when an officer or man of the engine-room department is on trial for departmental offences. Age for age with the executive officers, their *quasi* rank is utterly disproportionate, considering also their great responsibilities. The number of engineer officers in the highest rank to which they are permitted to attain is also disproportionate, as is also their pay on promotion, and their retention beyond the age of 50, seeing that the wear, tear, and close confinement of their profession is more exhausting than in the case of deck officers. There is no representative of the engineering department upon the Admiralty Board, although representing one-third of the total *personnel* of the Navy, and responsibilities in connection with nearly the whole of the *matériel*. The engine-room complements are too small to meet the stress of actual warfare, or the losses that may then occur. No writers are allowed to the chief engineers, and no re-engaging pay is given to stokers as to seamen. The obvious remedy for most of these evils is that the naval engineers should be recognised as a Royal Military Corps as much as are the Royal Engineers or Artillery of the army. It is possible to imagine a battle on land without engineers being called upon for services, but it is impossible to imagine a battle at sea without the main executive responsibilities lying with the engineering department. In such case the chief engineer should be granted rank as vice-admiral, and commanders, captains, and lieutenants should bear a similar ratio to the *personnel* of the engineering department as in the executive department. It is pleasant for us to be able to record that at least one vice-admiral of great popularity of the present day—viz., Lord Charles Beresford, who is wont to boldly express his opinions —has endorsed this view at a public dinner, *i.e.*, that of the Institution of Mechanical Engineers, that he, at least, would be glad to see the Engineer-in-Chief and the Chief Constructor of the Navy honoured with the rank of vice-admiral. Even so far back as 1876 the committee presided over by the late Admiral Sir A. Cooper Key recommended "that the engineer officers should be classed with the executive or military branch." If such a change were necessary then, how much more so is it at the present day? The Americans have led the way, and grappled with the difficulty in a far more drastic manner than proposed above, and are about to absolutely amalgamate both departments of the service, so that an executive, or fighting, officer must be prepared to do duty either on the bridge or in the engine-room. Why not? Engineer officers of the army have shown themselves —particularly in these latter days—splendid generals, with a gift for organisation and attention to material, transport, and details that goes far now to ensure success. How much more would that be the case where the absolute fighting material is, as the First Lord of the Admiralty expressed it, a floating museum of machinery. With such strong advocates in the highest governmental and executive branches of the Navy for the recognition of the importance of the naval engineer as a fighting officer, the reforms demanded cannot be long in coming.

AGAIN we have to deplore a serious disaster to an Atlantic liner, the ill-fated *Paris*, though, fortunately, unaccompanied with loss of life. The stranding of this vessel upon the Manacles Rocks, within a stone's-throw of the foundering of the *Mohegan*, has given a further notoriety to this dangerous point of coast, and at the same time has increased the bewilderment as to how such well-found and appointed vessels can find themselves so far from their proper course as to run stem on to the British coast. Where the course is, as it was, from Cherbourgto New York, one would have thought that there was sufficient room in the English Channel to enable steamers, not prevented from lying any predefined course by stress of weather, to keep clear at least of fouling the British coast. The succession of accidents upon these rocks has given rise to old traditions that the rocks about this part of the Cornwall coast are magnetic, and serve to produce deviation of the compass. But we fear that there are other possibilities of deviation from a supposed course in misty weather, where so much is left to dead reckoning, that will serve to explain the disasters of the *Paris*, the *Mohegan*, and the *Stella* without falling back upon traditional magnetic rocks serving to remind one of the voyages of Sindbad the Sailor. Where a course is set obliquely across the English Channel the tide, whichever way it is running, must serve to produce considerable leeway; and should such tide be abnormal in velocity or time of running, as may easily on occasion occur, the extra leeway in a long board may easily produce an error of some miles in the point of arrival. In the case both of the *Paris* and the *Mohegan* the Lizard was evidently the point aimed at, though from different points of departure;

and it would appear that long experience of the average accuracy of dead reckoning by the course set and the miles run, or the revolutions of the engine noted, are apt to breed a confidence as to position that abnormal circumstances may completely upset. We still want a warning instrument of the near approach of coast or other obstacle if such an apparatus can be devised. If not, nothing can replace the precautions necessary in thick weather to ascertain from time to time the possible position of a vessel, always to be taken on the assumption that she may be considerably out of her supposed position by mere dead reckoning.

WE are glad to see that the Institute of Marine Engineers is successfully doing the paramount duty of such an Institute in providing to its members and, through them, to the general engineering public, information, embodied in papers communicated to it, which will add largely to the scientific and practical knowledge of marine engineers, constructors, and naval architects. This has been particularly exemplified by two papers communicated to the Institute on May 8th. The first of these was that by Mr. J. T. McArthur, entitled, "A Comparison between the Performances of two Steam Ships." Although this paper was comparatively short and very modest in its tone, as perhaps befitted the scanty ground covered by the two comparisons given, yet this paper marked an epoch in the Institute, inasmuch as it gives to the shipmasters, engineers, naval architects, and all interested, comparative results in the two ships as actually obtained at sea. It only requires that these comparisons and records should be multiplied by the only men who have an opportunity to do so, viz., the sea-going engineers, to accumulate most important evidence as to results, which should bear good fruit in guiding the united efforts of constructors and engineers in producing the most economical steamers possible. In the present instance the summarised results of the two vessels in form of coal consumption per ton carried per mile show such surprisingly different results in the two vessels, that the one becomes a model to imitate, and the other one to avoid. When, however, it is found that the tonnage and dimensions are considerably different and also the indicated horse-power—whilst in one a dynamo producing 5,000 watts was driven, and in the other there was no dynamo at all—the startling fact that one steamer required more than a third more consumption of good Welsh coal per ton carried per mile loses somewhat of the lesson that may be deduced, from the difficulty of determining in what special points the loss of the worse vessel occurred. Probably the loss was an aggregation of deficiencies on all points, from the lines of the hull to the conditions of the working of the boilers by a certain amount of mismanagement in having allowed caking and deposit in the boilers, from excess of engine oil passed through the high-pressure cylinder. The conditions of coolness and comfort in the stokehold and engine-room, and dust in the latter, in the worst of the steamers, may in themselves have had a good deal to do with the worse conditions of economical stoking in that steamer. And as was remarked by the Chairman, it was not to be expected that there could be much economy in a ship in which there had been three chief-engineers in four years. Whatever the drawbacks of the particular comparisons given, as leading to any accurate deductions, we would again emphasise that the paper indicates a line of information which no Institute but that of the Marine Engineers can be so fitted to give; and of which the importance, when comparisons, if always carried out on the same basis, have become numerous, cannot be too highly estimated. By all means let us have some more of such comparisons.

A PAPER of much higher ambition, and one that, as a matter of research, would be a credit to any of the older and longer established technical institutes, was that communicated by Mr. Halliday, on "Experiments on the Heat-Absorption Power of Water," with a view of ascertaining the effect of the speed of water circulation in the absorption of heat. It must be remembered that the various devices once adopted by engineers to accelerate and determine the circulation of water in boilers have much been discounted by the experiments of Mr. Yarrow, by which it appeared that, water readily determines its own path of circulation, and will as readily circulate downwards as upwards in a tube subjected to the impact of heat. Mr. Halliday now presents the other point of view, that however the direction of circulation may be determined or may determine itself, the speed of such circulation over a heating surface is of vital importance to the quantity of water heated in a given time and to the amount of heat units thus absorbed. From the experiments carried out by Mr. Halliday with constant application of heat to a flowing stream of water, the velocity of which may be regulated, it undoubtedly appears that there is a point of maximum velocity up to which the absorption of thermal units by a flowing stream of cold water steadily increases, though the actual temperature of the resulting heated volume of water will naturally decrease. Beyond such maximum velocity the amount of absorption of the thermal units decreases. This is a curious result, which requires some thought and investigation, in order to determine the best velocity of water over a heating surface so that it may, in a given

time, absorb the greatest quantity of thermal units from a given source of heat. As thermal units are the product of two factors—the mass of water heated, in a given time, by the rise of temperature in the mass—the problem would appear analogous to the problem of the maximum condition of effective work units from a water wheel, turning with the flow of the water, where the work units are the product of effective pressure upon the wheel into the velocity in a given time with which that pressure overcomes a similar resistance. As the effective pressure upon the wheel also reduces as the speed of the wheel increases, it will always be found that there is one particular velocity of the wheel relatively to the flowing or falling water at which the wheel effects the maximum working effect. There appears to be some analogy; but in Mr. Halliday's heat experiment, though the water is there, which is the wheel?

The four torpedo-boat-destroyers built last year by the firm of F. Schichau, in Elbing, for the Imperial Chinese Government, made on their trial trip in free open sea a mean speed of 35 to 37 knots per hour, unattained hitherto, they proved their great sea capacity. All the four destroyers have steamed from Elbing through the Baltic, the German Ocean and Biscay around Gibraltar, through the Mediterranean Sea to Port Said, having run the way from Port Said to Colombo on a stretch without touching the port of Aden, a distance of 3,550 sea miles (about 4,100 statute miles), in quick, irreproachable passage. The destroyers had, after their arrival at Colombo, a large quantity of coal on board; this is a new great triumph for the economy of coals of the Schichau engines, and Schichau has splendidly solved the difficult problem to build such small vessels with a radius of efficiency of 3,000 to 4,000 sea miles. All the four destroyers continued their voyage to Northern China from Colombo after two or three days' rest. Hitherto, the voyage of the four destroyers has been going on without any interruption and without the least delay, as well as with the very least repairs to the engines and boilers.

EXPERIMENTS ON THE HEAT-ABSORPTION POWER OF WATER.

THE following paper is an account of experiments carried out by Mr. G. Halliday in the Institute of Marine Engineers to ascertain the heat-absorption power of water at different temperatures and different velocities across the surfaces:—

The apparatus (Fig. 1) consists of a glass vessel H with a spiral tube sealed into it. Water flows from F through the spiral tube and out by L into the cubic centimetre measure G. The quantity of water flowing through the tube can thus be determined. Steam is generated in the flask D, and flows through the copper spiral C, where it becomes superheated, and flowing into H heats the water as it flows through the coil. The temperature of the water as it flows in the glass vessel H is measured by a thermometer at B, and its temperature as it emerges from the coil is measured by a thermometer at A. The water then flows through L into G, and the number of thermal units given to the water as it flows through the coil J can be determined.

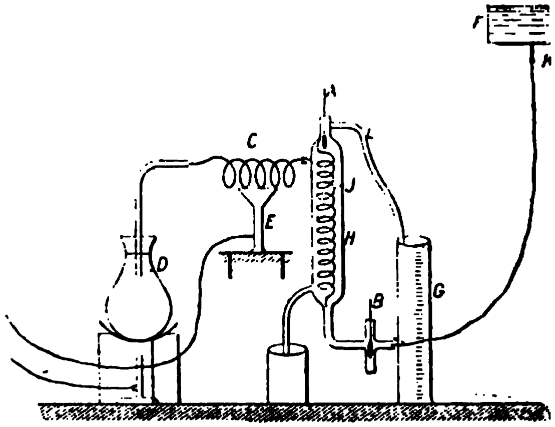

Fig. 1

At first a small copper tank was used between the thermometer B and the source of water. This tank was utilised for raising the temperature of the water before it reached the glass coil. It was found, however, that this arrangement of heating the water before it reached the glass coil did not give constant temperature, as the following results show.

The experiments were made to determine what influence the rate of motion through the tubes had on the water. It will be observed that the quantity of water flowing through the glass spiral J was 5 cubic centimetres per minute. The difference of temperature in the first case was 45·16 deg. Fahr., and in the second case 43·06 deg. Fahr. The times and quantities of water flowing through the glass coil J were taken at the end of each minute.

A.

Experiment when water flowed through the Coil at an Average Rate of 5 Cubic Centimetres per minute.

Time.	Quantity of water in c.c. measure.	Temperature of water when it emerged.	Temperature of water at entrance.	Difference of temperature.
4.39	705	154	109	45

Mean quantity of water flowing through in cubic centimetres, 20·7; average difference of temperature, 43·05.

	Quantity of water per minute.	Thermal units per minute.
In Experiment A.	5	225
In Experiment B.	20·7	891

The source of heat for the generation of steam and heating the coils remained the same throughout. The mean difference of temperature was about the same in each case. The increase of the number of thermal units which were taken up by the water when moving at the high velocity is very marked.

In the next set of experiments the water was led directly from the tank F to the thermometer B. When it was led through the small heating boiler the flow was somewhat intermittent, due to air getting into the boiler. There was also some trouble with the arrangement of the thermometer for taking the temperature of the water as it issued from the spiral. In the new arrangement the thermometer was directly inserted in the end of the glass spiral, and the fluctuation of the thermometer was then the fluctuation of the temperature of the water as it came out of the spiral. One set of readings will show the steady nature of the temperature which came from the tank under the new conditions.

C.

Time.	Quantity of water in c.c. flowing per min.	Temperature of water at A.	Temperature of water at B.	Difference.
3.0	610	140	52	88
3.1	620	131	52	79
3.2	640	136	52	84
3.3	665	137	52	85
3.4	680	141	52	89
3.5	700	143	52	91
3.6	720	143	52	91
3.7	740	143	52	91
3.8	760	141	52	89
3.9	780	135	52	83
3.10	800	142	52	90

Average c.c. flowing through per minute, 19; average difference of temperature, 86·2.

Thermal units per minute given to the water = 1637·8.

The result of this set of experiments, arranged in order of the velocity of water flowing through the tube, is as follows:—

D.

Average quantity of water per minute, c.c.	Average difference of temperature.	Thermal units per minute.
9·2	150·6	1388
19	86·2	1687
32·2	147·9	4759
47·7	39·5	1884
49·4	86	4278
84·5	52·6	4445

In this set of experiments there was considerable variation of the heat applied to the steam superheater and generator, and the result shows considerable fluctuation.

In the next set of experiments the heat of the gas generating steam and superheating was kept constant. The result of the sets of readings, arranged in order of the speed of flow through the spiral, is:—

E.

Average quantity of water per min, in c.c.	Difference of temperature.	Thermal units per minute.
7·2	152·1	1095
10·55	151·5	1606·5
15·5	118	1829
20	88	1760
30	61·7	1851
47·4	37·7	1786·9
61	32	1952
61·3	28·5	1746
75·5	30·8	2325
89·1	26·6	2370
91·6	24·9	2280
150	16·4	2460

Two trials were made with the gas at the generator and superheater, the same throughout the experiments.

F.

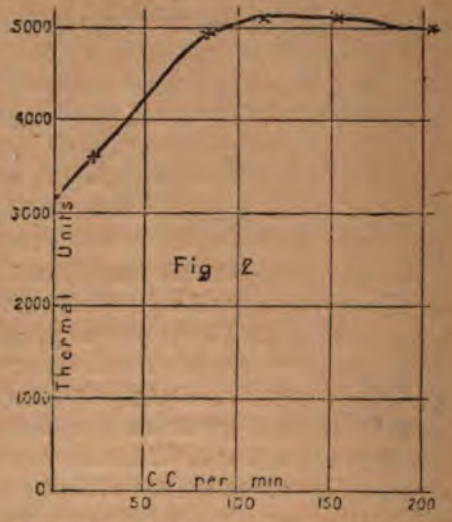
Average quantity of water per min. in c.c.	Average difference of temperature.	Thermal units taken up by water per min.
23·5	74·4	1748·4
120·8	20·3	2452·2
144·1	17	2449·7

The steam was afterwards generated very rapidly and super heated, and the following results were obtained:—

G.

Average quantity of water per min.	Average difference of temperature.	Average thermal units per min.
24	152	3648
81·2	60·6	4920
118	43·2	5123·5
160	32	5120
210	23·8	4998

It will be seen from the two last deducted results that there is a maximum coefficient of transmission of heat. This is also shown in Fig. 2, where the abscissæ represent the velocities of the water and the ordinates represent the thermal units absorbed by the water flowing through per minute. In Table F the middle one is the higher number, and the third from the top is the highest in Table G. It is also to be noted that the numbers of thermal units in Table G are much higher throughout than in Table F. This is in consequence of greater heat being used for generating steam and for superheating. This would appear to show that with this apparatus and with a certain heating arrangement there is a speed at which the maximum quantity of heat is taken in by the water. At a lower speed than this there is less heat taken in, and at a higher speed there is less heat taken in per minute per unit of heating surface.



The next set of experiments was made to determine whether water more readily absorbed heat at the point of ebullition than it did at lower temperatures. In a statement made by Professor Ser, he says, "When the water has come to the boiling point the movements are more than ordinarily tumultuous, and the transmission—of heat—is notably increased." It was sought to determine by the following experiments whether this notable increase of heat given to the water was due to its more rapid motion over the heating surfaces in consequence of the more rapid circulation, or was due to a change in the nature of the water which made it more readily take in more heat.

To do this, the water was made to travel through a straight tube instead of a spiral, in order that the bubbles of steam might rise quite freely. The tube was surrounded as in the last case. At first this surrounded barrel was only 12 in. long, but with as strong heat as possible the water could not be got to rise to the temperature of 212 deg. A longer jacket was then fitted on and carefully covered with asbestos, and strong heat supplied both in the generation of steam and superheating. The water began to boil quite freely, and the thermometer stood at 212 deg. The record of the experiment is given below :—

H.

Time.	C.c. of water per minute.	Temperature at outflow.	Temperature at inflow.	Difference of temperature.
2.39	435	211	55	156
2.40	450	212	55	157
2.41	465	212	55	157
2.42	480	212	55	157
2:43	500	212	55	156
2.44	515	211	55	156
2.45	535	211	55	157
2.46	555	212	55	157
2.47	575	212	55	157

Av. c.c. per min. 17·5 Average difference of temperature 155·4
Thermal units per minute .. .. 1787·1

The water was afterwards made to flow a little faster, while everything else remained at about the same. The temperature stood about 197 deg. Fahr. at the outlet, so that the loss by radiation would be about the same in both cases. Steam was supplied at the same rate and superheated without alteration. The result of the experiment was as follows :—

I

Time.	C.c. per minute.	Temperature of outflow.	Temperature of inlet.	Difference of temperature.
2.51	35	195	53	142
2.52	65	197	53	144
2.53	95	200	53	147
2.54	125	195	53	142
2.55	155	196	53	143
2 56	190	197	53	144
2.57	220	197	53	144
2.58	245	197	53	144
2.59	275	197	53	144
4.00	305	197	53	144

Aver. c.c. per min. 30 Average difference .. 143·8

The number of thermal units transmitted to the water per minute is 4314, as against 1787 when the water was at the boiling point.

The difference of the conditions in the two cases is the more rapid motion of the water through the tube, and it appears that the coefficient of transmission derives more advantage from quick motion over the heating surfaces than from the new properties in the water at the boiling point.

Keeping the heating arrangements the same, a series of experiments was made with this apparatus to determine the effect of the velocity of the water, with the following results :—

J.

C.c. per minute.	Average difference of temperature.	Thermal units transmitted to the water per min.
36·5	129 4	4684
77·5	67·8	5254·5
106 2	51·4	5458·6
135	40·2	5427
175	26·2	4585
205	13·4	2747

Here again there is a maximum transmission when the flow of the water is a little over 100 cubic centimetres per minute—see Fig. 3.

There was a fear that the bubbles of steam as they rose to the surface of the water in the tube would condense in the overflow tube, making the water in it at a higher temperature than when it was sent away under the boiling point. So the temperature of the water was measured as it flowed from the tube into the cubic centimetre measure.

It will also be noticed that the experiments made by Professor Ser, MM. Thomas and Laurens, and other experimenters did not make provision for the separation of the circulation factor from the factor provided by the new properties of the water at the boiling point. In one case there was a pot with a steam jacket underneath it, and the water was boiled in this. In the other case the water was heated with steam passing through a spiral tube placed in the pot; when ebullition began, rapid circulation took place, due to the entraining action of the steam bubbles.

In the apparatus (see p. 99) the circulation produced by the entraining action of the steam is done away with, and only the new properties gained by the water at the point of ebullition remain to increase the heat-absorption power of the water.

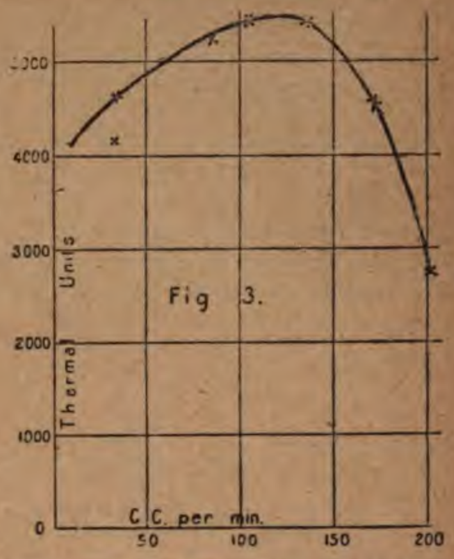


Fig 3.

It may also be pointed out that the condition of water when bubbles of steam are forming and mixing with the water does not appear to improve its heat-absorption power. Here, any way, are the records of the two sets of experiments. The steam generated and the superheating was the same throughout both.

K.

175 Aver. difference of temperature 160

19·4

Average number of thermal units of heat absorbed by the water at boiling point, 3113·7. The temperature of the water as it left the tube to flow into the c.c. measure was 178 deg.

The water from the tank was increased in velocity until steam bubbles stopped rising. The temperature fell to 202 deg. The water at the inflow rose to 53 deg. The following was the record of this experiment :—

L.

Time.	Water in c.c. per minute.	Temperature at outlet.	Temperature at inlet.
7.42	440	202	53
7 43	465	202	53
7.44	490	202	53
7.45	320	202	53
7.46	545	202	53
7.47	570	202	53
7.48	600	202	53
7.49	625	201	53

Aver. c.c. per minute, 26·43; aver. difference of temperature, 149.

Average number of thermal units absorbed per minute was 3933·6. The temperature of the water as it left the tube to flow into the c.c. measure was 180 deg.

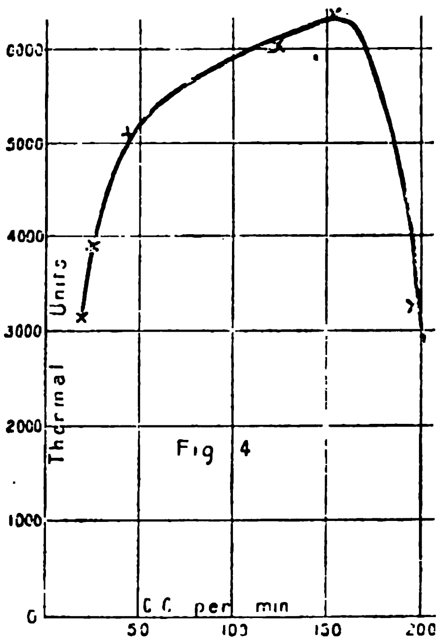
The increase in the number of thermal units absorbed by the water at 10 deg. below boiling point was thus 819·9. The statement made by the French experimenter was that at the boiling point the water takes in three times as much heat as at other temperatures.

The velocity of the water was again changed in order to note the effect of the change of velocity on the heat-absorptive power. The result is given in the table below:—

M.

C c. per minute.	Difference of temperature.	Thermal units absorbed per minute.
19 4	160 5	3113·7
26·43	149	3933 6
46	111·3	5119·8
125	48	6000
158·6	40	6314
193 3	17	3286·1

The accompanying curve—Fig. 4 - shows the manner in which the absorptive power increases with the velocity, and then falls off again after a critical velocity. The falling off is due to insufficient heat being supplied to meet the requirements of the more rapidly moving water. The same conditions would be found were there hot gases instead of steam, for the heat of the gases after a certain speed of the water would get forward with insufficient quickness to supply the water with ever-increasing thermal units.



MESSRS. TOLCH & CO., OF FULHAM.

THIS firm has a site most convenient for the launches and other small craft being taken down to the river, and if the numbers which have already been built for England are a sign, the firm has very fair success. A small launch, 20 ft. in length, had been only a few hours in the water before we went down to the place. It had been fitted with the patent reversible propeller Fig. A and with a single inverted cylinder launch oil engine, constructed on the Capitaine system. The oil was stored in the bow of the boat in a cylindrical tank, carrying a day's fuel, 2½ gallons. There was also a simple starting gear, which consisted of a small belt and a handle with a shaft, on which was fixed a small pulley. The shaft was inserted in a cylindrical hole on the end of the engine, and the belt enveloped the small pulley and a fly wheel fitted on the shaft of the engine. The shaft of the small pulley was fitted on an eccentric gear, worked with a small lever with a pin. When the belt has to be tightened, the lever is pulled back, it raises the small pulley by the eccentric motion, and when tight enough, the pin attached to the lever is let into one of the holes which hold the pulley in place. The handle is then turned and the engine started.

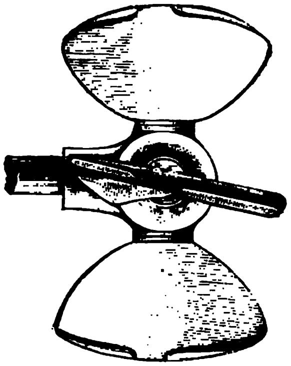


Fig. A.

Before we went down to the launch we were shown the engine Fig. 1A in the shops for driving the small dynamo. This dynamo serves twenty 16-candle-power incandescent lamps, and a hundred volts are obtained when the speed of the dynamo is 1,350 revolutions. The engine had to run about 400 revolutions and before it started we had the advantage of seeing the operation of heating up the vaporiser. This vaporiser is in the end of the engine: it consists of a vessel of cast iron, with a series of ribs all round it to promote the heat being taken up by the vessel. This vaporiser is charged with a small spirit oil lamp to it. The valve admitting the oil is forced open by the pump, which admits always a fixed quantity of oil. The air is drawn in by a valve at the top by the suction action of the piston. The exhaust valve and petroleum pump are worked from the crank and are under the control of the governor. When the speed gets too high, the governor cuts off the oil supply and the exhaust valve. The valves are thus motionless until the speed comes down. We cut out the propeller from the shaft several times, and in no case did the engine race. And when the propeller was placed at different notches, the speed of the engine kept quite constant throughout.

But coming back to the shop engine, which was of the type shown in Fig. 1A, and of three-brake H.P. A small spirit lamp was inserted under the vaporiser and allowed to heat that up. It heated it up for about five minutes, and when that had been done a small hand pump was worked at the side of the engine, which put about 6 lbs. pressure on the oil, and the tap was then opened and the oil permitted to enter the vaporiser by the valve. There is another little pipe which serves as a lamp on the outside of the vaporiser for heating that. The spirit lamp was now taken out and the stationary lamp lit to heat the vaporiser. The fly wheel was given a few turns and the engine started. The belt was also put on to drive the dynamo and all the lights switched on. A counter was used and showed a record of 440 revolutions for the engine, and 1,400 revolutions for the dynamo.

The volt meter showed 100 volts and the ammeter 8 amperes. There were 20 Ediswan lamps. Each charge of oil was $\frac{3}{100}$ of a cubic inch, and an explosion was made every second revolution. In this shop engine it will be seen that the pistons move out in opposite directions simultaneously, and the cranks being at right angles to each other, the reciprocating parts are balanced.

The launch engines are vertical, but they are worked in precisely the same fashion as the one already described. They are made single-cylinder engines, from one to 15 brake H.P., and double-cylinder, from six to 60 H.P. That fitted in the small 20 ft. launch was two brake H.P., making 420 revolutions per minute. The propeller shaft as it came from the engine, was $1\frac{1}{8}$ in. diameter, and after it went past the thrust block $1\frac{3}{4}$ in. diameter. The reversing of the motion of the boat, to cause it to go astern, is produced by the reversing of the blades of the propeller. The arrangement goes further than this, for the blades may be set at intermediate positions and held there by means of the lever going into a notch. The propeller has a hollow boss *a*, which is screwed into the shaft *b*, and there is a cap *c* fitted in the other end, Fig. 3. The blades, d d^1 have shanks and they can rotate through a certain angle in a bush *f*, screwed into a boss *g*. A pin *h* on the end of d^1 fits into a hole in the end of *d*. A collar *i* is screwed on to the blade and the bush *f* prevents the blades from coming out of their place. The cranks are shown at *j j*, and these fit into slots n *k*, and by this means the blades are moved. The plate *k* is thus like a crosshead moving in the guides *m m* and caused to move backwards and forwards by the rod *n* connected to the reversing lever.

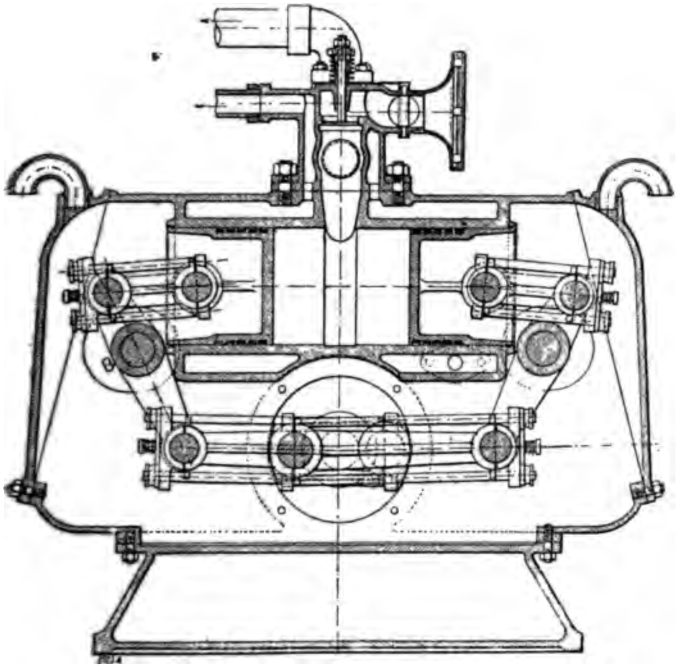

Fig. 1A.

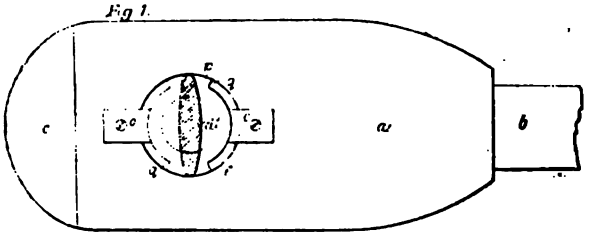

Fig 1.

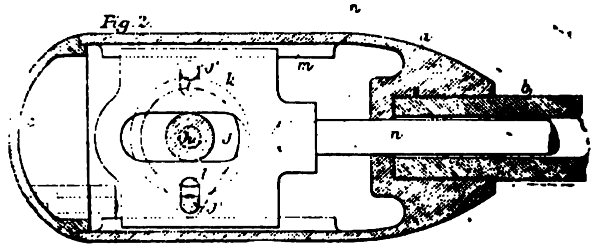

Fig. 2.

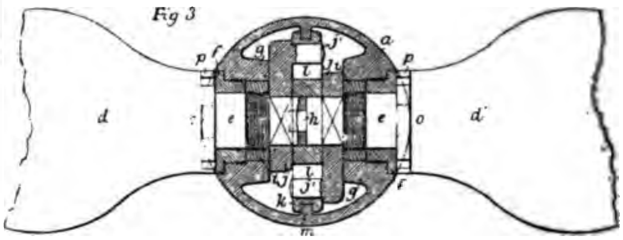

Fig 3

We moved the lever backwards and forwards after the engine had been heated up, and it kept making the same number of revolutions in whatever position the lever was placed. The current of the river was strong, and against the tide this small two H.P. oil-engine took $10\frac{3}{4}$ minutes to run a mile, and with the tide $7\frac{1}{4}$ minutes. At places where there was plenty of water it turned, with the helm full on, in little more than its own length. The engine is covered in with a wood casing, which became slightly heated just above the vaporiser; but there was not the least smell from the engine, and everything about the boat was spotlessly clean and it was evident could be kept so. The over-all dimensions of this engine were 31 in. in length, 23 in. in width, and 40 in. high. Cast iron ballast blocks had not been fitted in the bottom of the boat, and when one moved from side to side the boat went with them. There was accommodation for about twelve persons in the launch, and save for the little thumping of the exhaust at the stern there was no inconvenience felt in the least. The circulating cooling water is drawn in from below and discharged above water level at the side. The temperature of the water, as indicated by the hand, was little above that of the inlet water.

The illustration shows an oil motor launch fitted with a steering wheel close by the reversing lever, and it shows the compact nature of the machinery. In the

bow is shown the oil tank and in front of that the chain locker. The figures 4 sufficiently explain themselves.

Messrs. Tolch have fitted a 15 H.P. engine in a cargo boat (250 tons) trading in the Highlands of Scotland, and so satisfactory has been its working that a repeat order for an oil engine of 20 H.P. has been given for a twin-screw cargo steamer. It will be seen from the drawing, Fig. 5, that the shaft of the engine has been placed athwartships and connected to the shafts of the twin-screw by means of bevel wheels. The distance between the centres of shafts is 7 ft. 6 in. The reversing motion of this engine is produced by two bevel wheels and the reversing lever moves the forward or aft bevel wheel into gear according as the motion is required forward or aft. The reversing levers are on deck as shown in Fig. 6, and by a system of link work they are connected to the clutch for the two bevel wheels. The plan of the engines are shown in fig. 7.

The cost of working these engines is given by the makers as ¾ pint of oil per brake H.P. per hour and the cost of this oil from a depôt a few yards further up the river is 4½d. per gallon. Twenty H.P. would thus use 15 pints per hour, and 45 gallons per day. That is 17s. per day for oil. A captain and two hands only are required in this 300-ton schooner. And the space required for the oil per day would be 7½ cubic feet. A similar steam engine would require to indicate about 25 I.H.P., and use 6 lbs. of coal per I.H.P. per hour, which would come out at 32 cwt. of coal per day. The cost of this would be at least 24s. and the space taken up by the coal for a day's run would be 70 cubic feet. Besides, an engineer with at least 8s. per day in wages would be required.

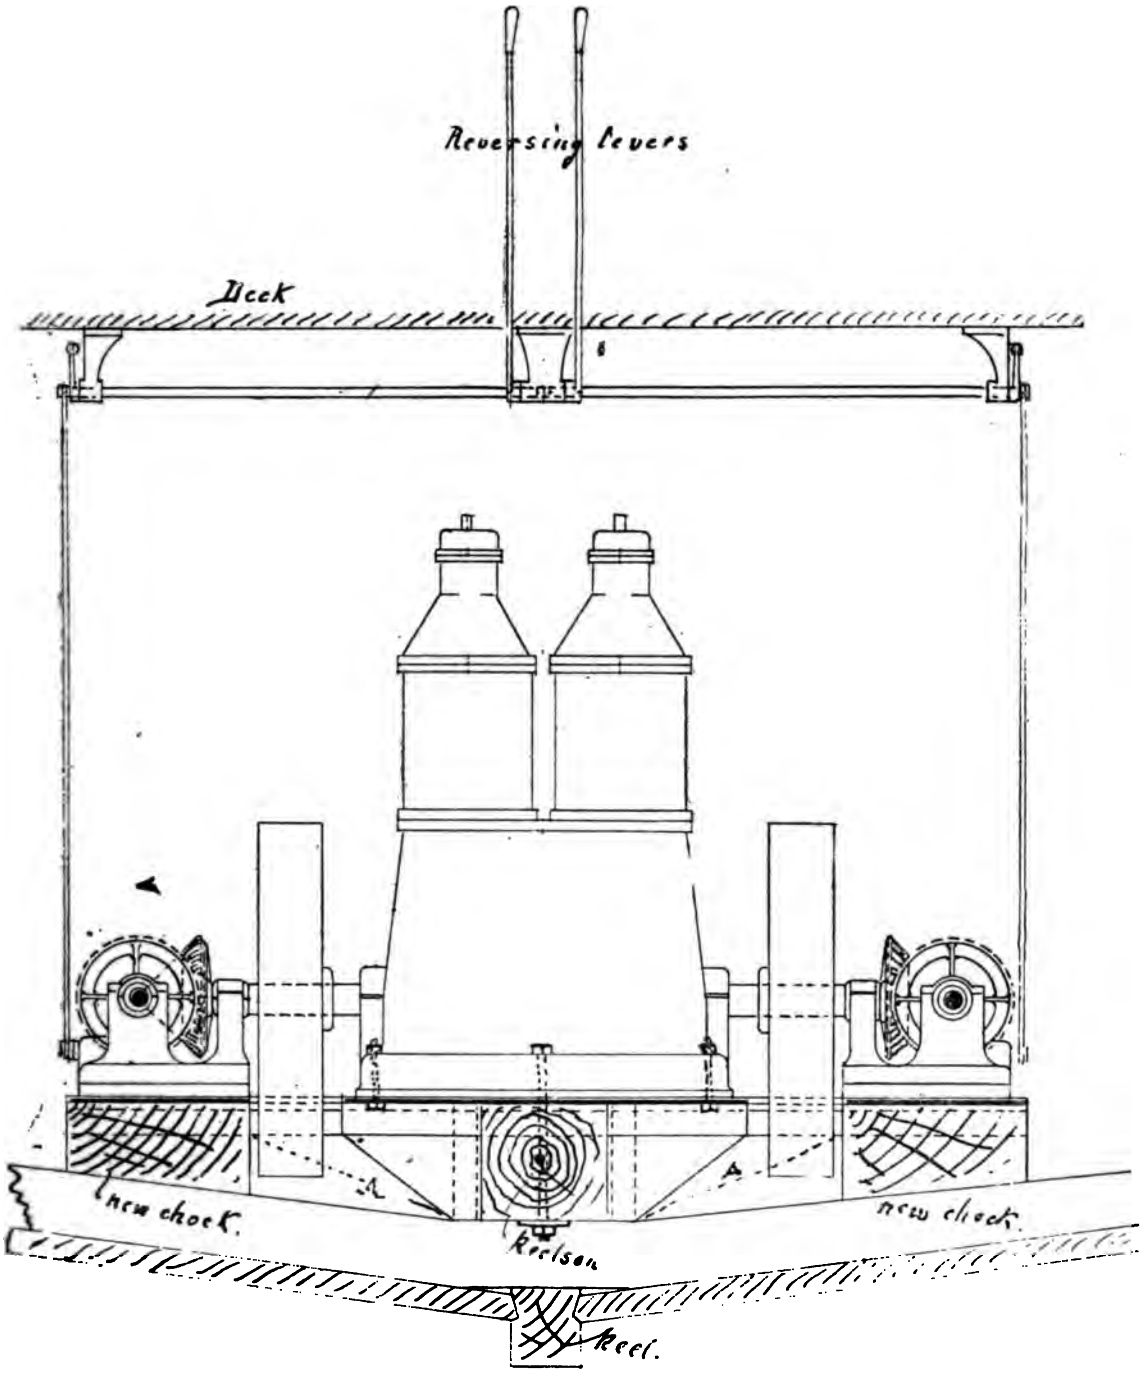

Fig. 5.

For small craft and small H.P. the oil engine has a future before it.

THE FLEETS OF THE MAIL LINES.

(From our own Correspondent.)

An Event of no Little Importance

to all certificated officers of the mercantile marine is the well-deserved promotion of Mr. Walter J. Howell to the position of Assistant Secretary of the Board of Trade in the marine department. Mr. Howell has long been principal clerk with Mr. Ingram B. Walker in the assistant secretaryship. The retirement of the latter-named gentleman, through regrettable ill-health, has enabled an appointment which will be universally acceptable to everyone who knows anything about the working of the department to be made. Mr. Howell, who has spent a quarter of a century in the Civil Service, is as remarkable for his courtesy as for his profound knowledge of all things concerning the mercantile marine. If the engineering branch of the service know less of him and of his work than do the navigating branch, it is because they are more seldom in difficulties and less often asking for reforms, and are, in a word, more contented with their position and their prospects than their compeers.

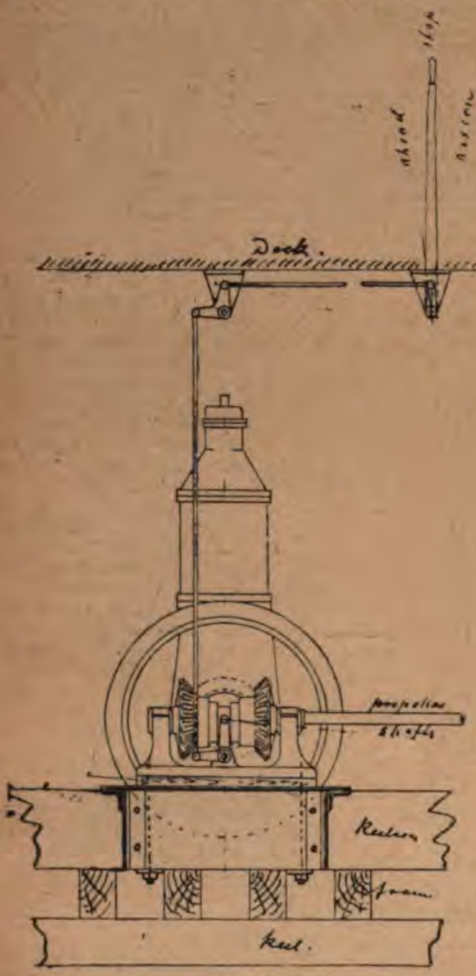

Fig. 6.

The City of Dublin Steam Packet Company,

who, with the building of the s.s. *Louth* in 1894, signified their belief that the time of the paddle, at least for their Liverpool and Dublin service, had gone by, launched the sixth of their screw boats for this trade in April, 1899. This was the *Cork*, built, as all the series have been, at Port-Glasgow, by Messrs. Blackwood & Gordon. Her approaching addition to the working fleet has enabled the company to dispose of the old paddler *Leitrim*, constructed a quarter of a century ago at Birkenhead by Messrs. Laird Brothers. The *Mayo* is now the only vessel of the old type left in their fleet, for the *Ireland* is also reported sold. This vessel was a famous ship in her day. She too came from Messrs. Laird's yard. But she is comparatively juvenile, having been launched in 1885. Her construction was agreed upon at the last acceptance by the Government of the old paddlers for the Holyhead and Kingstown mail service. It was stipulated that if the veterans were taken on again by the Post Office, a fine modern vessel should be constructed to aid them in their important work. She had the same length as the original boats, but 3 ft. more beam, and 6 in. more depth. Like them she had oscillating paddle engines, but her power was much greater. The cylinders of the old *Munster*—to take her as a type of the four original sisters—were 98 in. in diameter, and 84 in. stroke. The *Ireland's* cylinders were 6 in. greater in diameter, and 18 in. longer in stroke, but her machinery was on the single plan, and her boiler pressure was only 30 lbs., though she had forced draught. Though she came out so comparatively short a time ago, she was nevertheless considered a wonder in her day. An engineering paper of contemporary date, speaks of her in September, 1885, "as the fastest steamer afloat," on the results of her first trip across the Irish Sea. There were no torpedo-destroyers at that date, and doubtless the statement was an accurate one at the time it was made. At all events the vessel broke the record on her first appearance, making the crossing in 2 hours 58 minutes to the westward, and again beating the best previous known performance to the eastward, when she came back in 3 hours and 7 minutes to Holyhead. Her speed on the return voyage was 20.25 knots. The engines were in charge of Mr. Beavis, the engineers' manager. They indicated as much as 6,337 H.P., on the eastward trip, with 27.17 revolutions, yet there was only 27 lbs. steam. The number of revolutions seems high, at all events for that date, with the fact that her paddles are 33 ft. 4 in. in diameter, with eleven floats 13 ft. wide, and 5 ft. 9 in deep on each wheel. With the departure of the *Ireland* from their fleet, the old-established City of Dublin Company may be said to have left the paddle tradition behind it. The transition here has been rapid indeed. Five years ago the paddle ruled this company in both its mail and cargo service. Now they have but one paddle-ship in either service, and that is the *Mayo*, which in the ordinary course will soon follow her sisters of an earlier date into oblivion. It will be curious to see if the general concensus of opinion amongst practical managers of channel steamers, strongly accentuated by the choice of twin-screws for the new Royal yacht, will affect the use by the Kent Railway Companies of the old-fashioned method of propulsion. At all events those companies are only now kept in countenance in their conservatism by the highly subsidised steamers of the Belgian and Dutch lines.

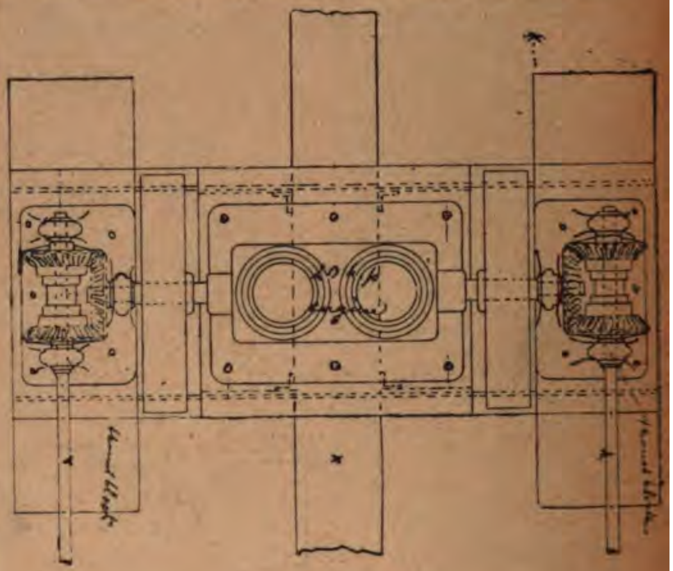

Fig. 7.

The Shaw Savill and Albion Company

have, as I mentioned last month, chartered one of their two finest vessels, the Denny-built *Tainui*, to the Allan Line. This vessel has not appeared for a long time now in the New Zealand trade, her last engagement having been to the Compania Trans-atlantica, where, under a portentous Spanish name, she was engaged in the transfer of Spanish troops to Cuba, when the Dons were trying vainly to cope with the insurrectionary forces. It would seem that the class of vessel which she represents is no longer altogether suited for the changed conditions of the New Zealand trade. She had a little too much speed, and was altogether rather too expensive in the cost of her working. New vessels of the *Aotea* type are taking the places of the older and more purely passenger ships. The *Kumara*, a fine big steamer with very large insulation for frozen mutton, has just been turned out for the line from the Dumbarton Yard, and the owners now announce that the *Arawa*, the speedier sister of the *Tainui*, is for sale. This vessel, like the *Tainui*, had a spell of work for the Spaniards. But she had another experience as well. It may be within the memory of some of my readers that when the Canadian Australian Royal Mail Steamship Company was deprived of the services of its steamship *Miowera* by an accident, which necessitated her coming to England for repairs, they chartered the *Arawa* for the interval, that vessel being at the moment within easy reach of Sydney, which was one of the termini of the Canadian Australian Line.

The Sydney-Vancouver Services.

Four days after the advertisement regarding the *Arawa* appeared, there was, curiously enough, a preliminary announcement to the effect that the line for which she rendered this service is coming into the market with its ships, its goodwill, and all its other property. It is to be offered in one lot as a going concern. This is rather a sad announcement, for it shows that another of Mr. James Huddart's undertakings has ended in more benefit to the public than to himself. One felt great sympathy with Mr. Huddart when the contract for the Fast Service to Canada, which he had so persistently and earnestly advocated, was given to Messrs. Petersen Tate & Company. That action on the part of the Canadian authorities does not seem to have benefited Messrs. Petersen Tate. It certainly did not aid the inception of the Fast Service. One felt, however, that the line to which Mr. Huddart then turned his attention might perhaps recompense him for his disappointment. The field between the flourishing port of Victoria, British Columbia, and the Australasian ports looked a promising one. He made a very good start with the two ships which he had built for it on the East Coast. These were the *Warrimoo* and the *Miowera*, which I described at the time they came out. The trade developed, and a third ship was needed. In an unfortunate hour the *Aorangi*, formerly of the New Zealand Shipping Company's fleet, was selected for the vacancy. A large amount of money was spent upon her to fit her for the new service. Her machinery and boilers were renewed, her passenger accommodation was reorganised, and she was sent out as a practically new ship. But the new interests introduced into the concern, and the heavy expenses incurred, were too much for the company. There was heavy litigation, and the line went into liquidation. Now we see from the announcement that the liquidator cannot see his way to continuing to work the line, and that thus he finds it necessary to dispose of it.

Messrs. Elder, Dempster and Company

have registered themselves as a limited company during the past month. The public has not had any opportunity of acquiring an interest in the business itself, which indeed is believed to be quite good enough for those who have built it up to wish to keep altogether for themselves. But outsiders have been allowed to apply for about six hundred thousand pounds worth of mortgage debentures, which are, of course, a first charge on the business. They thus obtain the best of security with the very tempting interest of 4½ per cent. It is interesting to observe of what the Elder Dempster Fleet—as distinguished from the several fleets, such as that of the African Steamship Company, the British and African Steam Navigation Company, and the Ocean Transport Company, which the firm manages—consists. The firm itself owns some seventeen steamers. Of these the greatest is the *Milwaukee*, of 7,317 tons gross register. The two smallest are the *Banana* and the *Yoruba*, of a little under three thousand tons each. The *Yoruba*, besides being one of the two least in size, is much the greatest in age. She has in fact attained the patriarchal age of four years!

Excluding her, none of the fleet are more than two years old. Messrs. C. S. Swan & Hunter are responsible for the building of five of these ships, whilst Messrs. Palmer's, of Jarrow, have constructed four of them. Messrs. A. McMillan, of Dumbarton, have turned out two. The *Degama* was built at Hartlepool, the *Yola* and *Banana* at Sunderland, and the remaining four vessels come from Clyde yards. The total tonnage exceeds 78,000 gross register. The vessels seem all to be in profitable employment, chiefly in the Transatlantic trade to United States and St. Lawrence ports. The return, as far as it can be arrived at, amounts to about seventeen per cent. on the valuation as estimated by independent authorities.

The "Fulda."

The extraordinary accident to the *Fulda* in a Birkenhead graving dock was the subject of a suit tried before Mr. Justice Bigham at the recent Liverpool assizes. A large amount of very expert evidence was adduced, and the trial occupied four days. Little fresh information as to the circumstances attending the disaster came out. We know that as the water left the ship ominous noises were heard; but such are not unusual under such circumstances. Then there was a report like artillery, as one witness described it. The stem of the vessel came down, then the middle ship, and lastly the stern, and in an instant the value of the *Fulda* was reduced from £37,000 to little over £11,000. The shock not only ruined the ship, but it split the very blocks on to which she had been let down. It appeared from the evidence that the ship had an unusual overhang forward. This extended as far back as 108 ft. from the stem, and probably no accident could have happened at all had she been so blocked that support was given to this part of her fabric. But no notice of her peculiar formation had been given by her owners either to the proprietors of the dock or to the firm which undertook the work of placing her in position. It was alleged that the blocks provided for her support were unfit for their work. But it was proved that the dock had been in use for forty years; that it had frequently been occupied by vessels of about her size within recent times, and that no accident had ever before occurred. In the result it was held that there was no blame to be attached to either set of defendants. The blocks were not in default, and there was no responsibility for what occurred capable of being attached to those who docked her. The peculiar construction and design of the vessel seemed accountable for all that took place. Notice of the peculiarity had not been given to either of the parties sued, and so they could hardly be held accountable for not taking special precautions in her case. A suggestion that her owners might be held liable for damage sustained by the dock itself through her collapse was sternly discouraged by the judge, and so the matter is—as far as one can see—finally closed. Shortly after the termination of the case the old ship left the Mersey on her return to Bremerhaven. The Canadian Steamship Company at least is not likely to see her again.

The Great Eastern Railway Company,

whose services to Holland from Harwich are certainly the best between England and the Continent both as regards ships and convenience of arrangements, has again provided an improvement for the benefit of those who patronise its route. For those who are travelling to Germany a saving of no less than 25 miles has been effected by the opening of a new Dutch line, whereby the detour to Amsterdam is avoided and Berlin is brought into a straight line of rail with the landing place at the Hook of Holland. The full benefit of the improvement will not be reaped, however, till the German authorities can be induced to run fast and complete connections through their territories in connection with the really admirable services provided by the Great Eastern Railway, both by sea and land, and by the Dutch Government through its State railways.

Liverpool

has now taken from Southampton the distinction of having the greatest graving dock in the world. The new Canada Graving Dock was inaugurated on the 2nd May, 1899, when the White Star cargo steamer *Cevic* was, without any ceremony, and in the presence merely of a few officials of the Dock Board and of the company which owns her, quietly received and accommodated. This is the way that characterises Liverpool, and contrasts strongly enough with the excitement that attended the Royal functions over the Prince of Wales Dock at the Hampshire port. A brief comparison of the principal dimensions of the two docks may be of interest: —Canada: length over all, 925 ft.; width at entrance, 94 ft.; depth of water on sill at high water, ordinary spring tides, 32 ft. 6 in.; capacity, 3,286,648 cubic ft. Prince of Wales: length over all, 750 ft.; width at entrance, 91 ft. 1 in.; depth of water on sill at high water, ordinary spring tides, 32 ft. 6 in.; capacity, *2,320,000 cubic ft. On the occasion of the docking of the *Cevic* the task of emptying the dock was completed in 1 hour and 40 minutes. This was effected by the use of three centrifugal pumps of 51 in. diameter, whose normal throw is 922 tons a minute, rising to an emergency capacity of 1,000 tons. There is an installation of six Babcock & Wilcox water-tube boilers to supply steam for the engines which drive these pumps, and the I.H.P. of the machinery is 2,200. I must add that, as I calculated out the figure marked thus * from rather doubtful data, I do not vouch for its accuracy.

The Compagnie Generale Transatlantique

inaugurated its intermediate service to New York, with the sailing of the *Woolloomoolloo* on May 9th. At present this service will be maintained by sailings once every three weeks. In connection with this there is a report that some famous ships are to be acquired by the company. Twelve months ago, when the war between Spain and the United States broke out, it will be remembered that the Spanish Government purchased three Atlantic liners of the first-class from the Germans. These were the *Havel*, of the Nord-Deutscher Lloyd Company—a fine single-screw vessel built by the Vulcan Company at Stettin—and the *Normannia* and the *Columbia*, of the Hamburg-American Steam Packet Company. These latter vessels were British-built twin-screw steamers, which had earned for themselves a very fine reputation in the passenger trade. From that day to this these steamships seem to have disappeared. They never did anything during the war, and they have remained in retirement since its close. Now, though there is nothing said about the *Havel*, there is a report that the Compagnie Génerale Transatlantique is buying the other two vessels for its New York service. Owing to the conditions under which it carries the French mails, it cannot use them in its Saturday mail service. But it would be quite possible to use them as extra steamers on other days. And it is thought that they may come in useful next year when the Paris exhibition is being held, and all the world and his wife is crossing from America to see the show.

The American Mails.

During the last few weeks the New York correspondent of the *Times* has seen fit to renew his attack on the British lines carrying the mails to New York. As on previous occasions he takes instances of letters and newspapers sent through our mails, and compares their transit with what their experience might have been if they had been sent in foreign bottoms. He is quite right to take what steps he thinks proper—if they be fair—to bring about any postal reforms of which he approves. But the remarkable thing about these comparisons is the fact that in every instance now, and in previous years, the case against the British ships is lamentably overstated. Now, one cannot expect a gentleman whose mission is to deal with questions associated with New York society, and with the higher international and local politics of America, to be personally very much imbued with a knowledge of steamship performance. He has his own engrossing and absorbing pursuits, and I know by experience that to carefully watch the mail lines takes up a great deal of time and attention. But a man who holds so responsible a position as that of the representative in the New World of the principal London journal ought to have at his command the best possible sources of information, and one of the elementary qualifications for his position should be the power to judge of the value of the information submitted to him. From what has recently appeared in the New York telegrams of the *Times* it would appear that the sources from which these attacks arise are bitterly hostile to British interests, and are not too particular when they can, either by suppression of fact, or by overstatement, make up an apparent case against the British Post Office and British shipowners. The *Times* and its correspondent know their own business, and can judge whether or not their position and standing will be advanced by the policy to which I refer. But the British shipowners, whose struggle on a very small Government payment for actual work done in the carriage of mail matter is already a very tough one—seeing that their competitors have large Government subsidies—have surely some right to expect that the representative London daily should not be used as the vehicle for exaggerated complaints as to the way in which they perform public services.

The Leyland Line,

which was incorporated as a limited company with a capital of £600,000, to purchase an old-established Liverpool business in the Mediterranean and Transatlantic trades, has just issued about £200,000 worth of debentures. We are thus afforded an opportunity of seeing the progress it is making, and the intentions of those who manage its affairs. It would appear that it now has a fleet of 28 vessels afloat; that since it bought the business it has re-engined and boilered five of its ships, and simply re-boilered one, whilst it has at the same time accumulated a sum of £374,000 in cash and investments. The money it is now raising will give it, with its investments, about half-a-million sterling ready money, which it proposes to expend in large additions to the fleet. About forty thousand tons of new shipping, in five bottoms, is to be added. One of the new ships will be a sister to the *Winifredian*, of 10,500 tons gross register, just built for the company at Belfast. The other vessels will be of a somewhat handier size, ranging down to 5,600 tons in the smallest of the quintet.

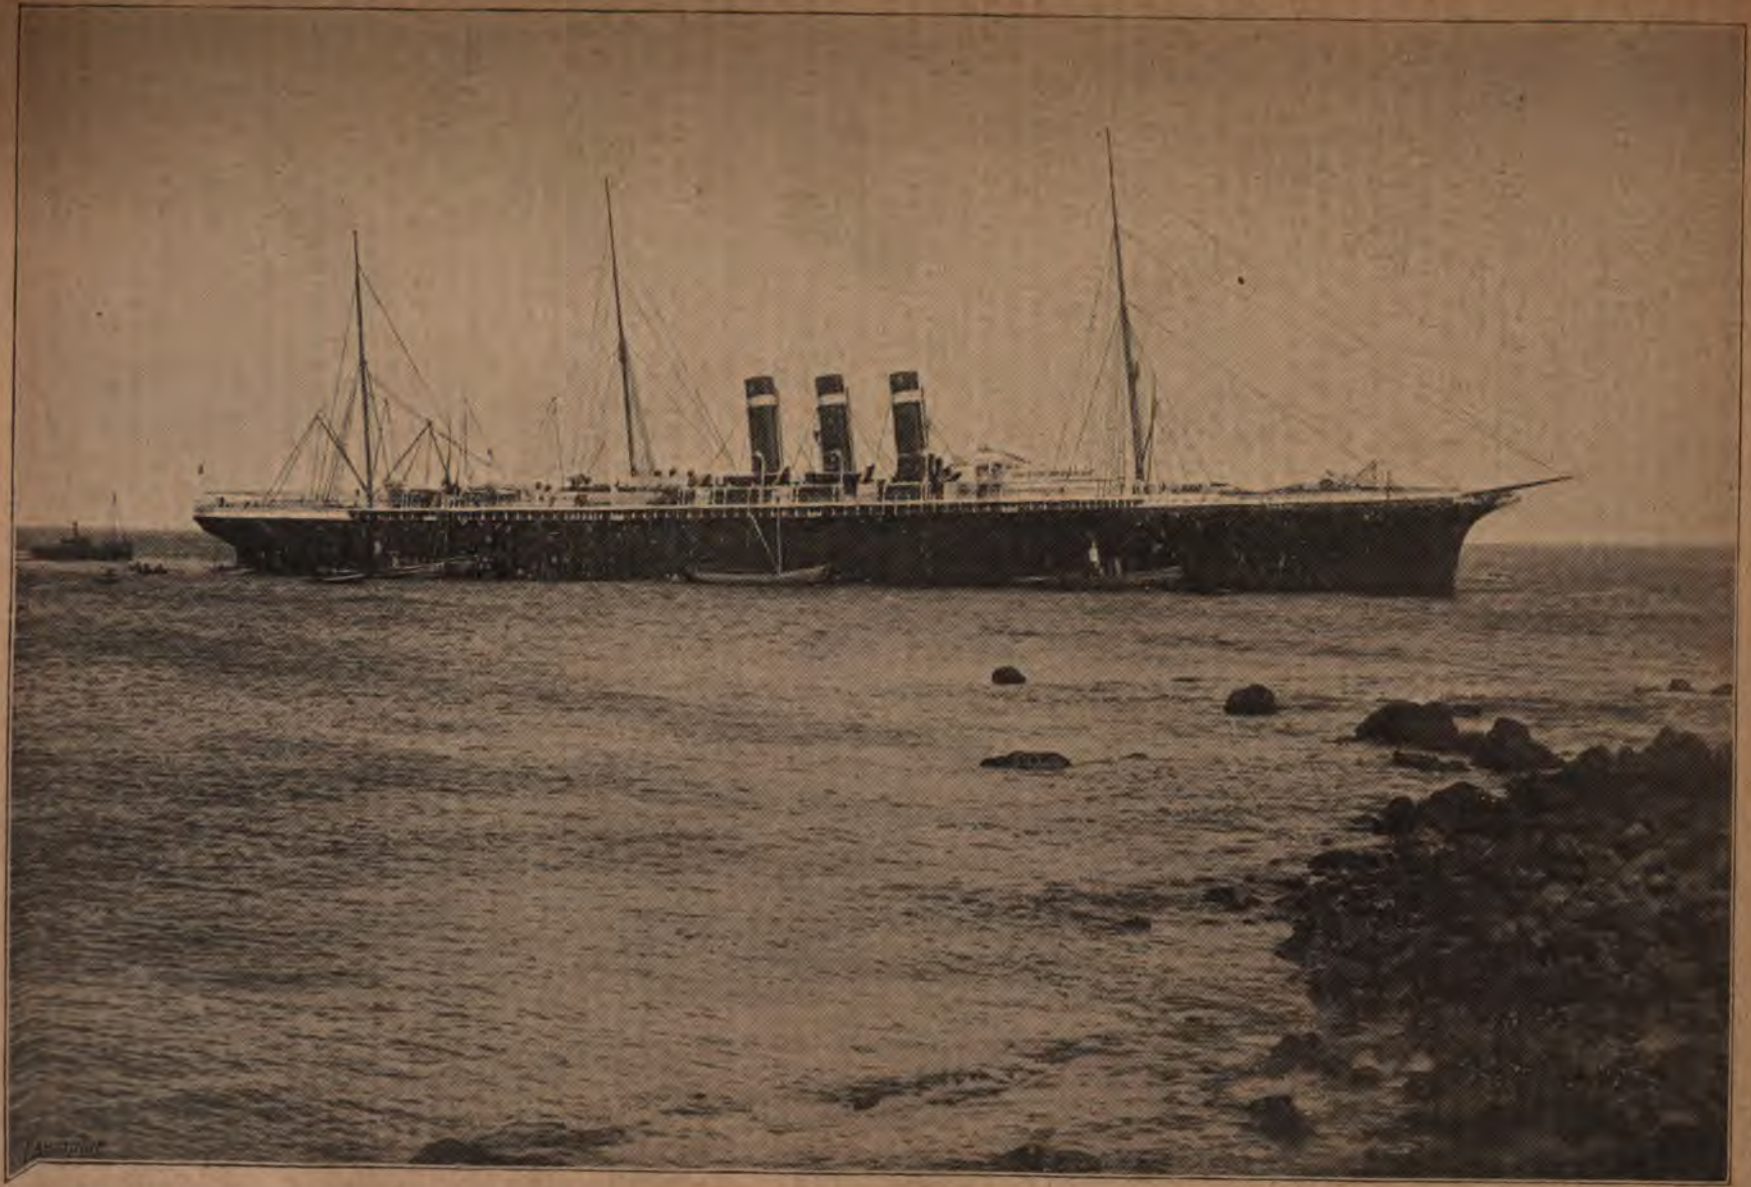
The Stella.

The inquiry into the loss of this vessel is now completed. As was altogether to be expected, there has been little result from these lengthy proceedings. The speed of the vessel is found to have been, under the circumstances, excessive. So much for the actual findings. As to the recommendations they do not amount to very much, either in extent or as to practicability. As about one-half of one per cent. of the lifebelts on board were found to be defective (though there were enough on board to give each person carried at least three sound ones), it is recommended that inspection of belts should be made at short intervals. No remarks on this point can be made save perhaps to inquire how frequently the Court would wish the inspection to take place. The desirability of carrying the boats swung out board in fog—when the state of the wind and sea allows—is also insisted on. Yet in the case under examination little gain could have been made by the adoption of this practice. In the evidence of Mr. Anderson, we have been given absolute data as to the splendid discipline of the crew as regards boat drill. By his watch the vessel struck at 4.11 p.m. That watch was stopped by water at 4.19 p.m. Thus from the time of striking till all was over it was eight minutes *at the most*. What time was taken up whilst the water penetrated Mr. Anderson's clothing and the case of a carefully made watch must be allowed from off that time. Surely better work could not have been expected under any circumstances. The Berthow boats do not come very well out of the test, for the time allowed was quite insufficient for their expansion. But it does not follow that these contrivances are useless altogether, because it is unusual for disasters to be so overwhelming and instantaneous. Then there is the recommendation that the booked time of arrival of the competing boats should not be identical or approximately so. It is thought by the Court that an alteration in this direction might avoid any suspicion of racing between the rival vessels. I do not agree with this. For if there be competition it will not be avoided by preventing the passengers from saying, "Such and such steamers always get in first." The answer to that will be that they start first also, and the rivalry, if rivalry there be, will merely shift to one of absolute speed. Then there is the suggestion of communication with the Casquets. With that there can be nothing but agreement. Moreover, it is possible that the invention of Signor Marconi's may not only aid us in effecting communication with the lighthouse from the land, but also may help the lighthouse-keepers to offer a warning note to vessels running into danger under the veil of fog. But time must be allowed for further experiments in this direction.

Strandings.

There are two unfortunate strandings to report this month. The first, in point of time, is that of the Allan liner *Gallia*, which, on her first trip up the St. Lawrence, has stranded on Sorel Island. It is hoped—though information regarding the whole matter is singularly meagre—that the matter is a trifling one.

The other accident is far more serious. It relates to one of the finest and largest vessels afloat, though the steamer in question is one whose name has unfortunately been previously in the disaster column. The American Liner *Paris* is not a lucky ship. She left her dock at Southampton at noon on Saturday, the 20th May, for Cherbourg and New York. Captain Watkins, who has had charge of her for so long—before ever he or she went on to the American register—was in command, and she passed Hurst Castle at 1.30 p.m. Running across to Cher-



(*Photographed by W. M. Harrison, Falmouth, on May 24th, 1899.*)

THE STRANDED "PARIS" OF THE AMERICAN LINE, SHOWING HER POSITION ON THE ROCKS AT LOWLAND POINT.

bourg to complete her complement of passengers and mails by embarking about fifty persons, she made her departure at 6 p.m., having then on board 140 bags of mails, 85 saloon passengers, 109 in the intermediate cabin, and 192 emigrants. Her crew comprised 372 persons, so that altogether there were 752 souls aboard her. As far as is known the weather was misty, but not actually foggy. But, at all events, some seven hours after leaving the French port the big ship ran on the Manacles, where on the 14th October last the Atlantic Transport Company's steamship *Mohegan* was wrecked with so great loss of life. As day broke the not very encouraging sight of the masts of that unfortuuate vessel were apparent, close to where they themselves lay, by those aboard the *Paris*. But their fortune had been far better than that of their predecessors. They had gone on to the Lowlands, which seems to be the only shelf of rock in the vicinity. There was no fear of the vessel sliding off and foundering in deep water, and eventually the mails, passengers, and baggage were conveyed to tugs and sent off to Falmouth, which is but eight miles distant from the scene of the mishap. The *Paris* lay with a list of but five degrees to port, and showed no sign above water of the precarious position in which she was. The crew remained on board. It was soon, however, apparent that she is very seriously damaged. Her fore part was full of water, and the fore stoke-hold was flooded. The diver's report as to the damage which he could ascertain was not very favourable, whilst he suggested that the double bottom had sustained very severe injuries. At the time of writing the prospects of floating seem very doubtful. We shall see. In the meantime, however, I am pleased to see that all the officers, from Captain Watkins downwards, maintain the utmost reserve. It is quite proper that they should. I cannot use words strong enough to express my opinion of the bad taste—to use no stronger expression—which prompts such letters as that of Admiral de Horsey, published in the *Times* of the 24th May. A casualty has occurred. Nothing that is written now can prevent that. Let us leave things as they are, and not rush into print to advocate our own little fads and to break down, as far as we can, the reputation of a distinguished seaman, and to minimise the precautions for safety taken by a great company which, since it opened its present line of communication, has never had a serious accident.

Some indication of the feeling amongst underwriters in regard to the prospects of refloating the *Paris* may be gathered from the fact that the rate of fifty guineas per cent. was paid for re-insurances in regard to her on the 23rd May.

A Famous Greyhound

will shortly be removed from the list of the fleets of the mail lines; for the *Alaska*, once the record-breaker of the Atlantic, has been sold for breaking-up purposes. It is long since she was seen on the New York route; but she, like other ships mentioned in this instalment of notes, served the Spaniards by taking troops to Cuba under an unfamiliar name. Since then she has spent a long time laid up in the Gareloch, where, as may be remembered, she on one occasion made as though she would founder at her anchors. She finally changed hands at the price of £17,500. In the next issue of notes I shall hope to give a more detailed memoir of her.

The P. & O. "China"

was dry-docked by her builders, Messrs. Harland & Wolff, on the 23rd of May. The delay had doubtless been owing to the great pressure of work—much of it of a very urgent kind—which they have long had on their hands. But the fact that the docking has taken place so recently shows fairly conclusively that all the rumours as to the owners' intentions regarding her have been quite unfounded and premature. They are not likely to make up their minds till the experts have carefully examined and reported upon her under-water damage.

The Castle Line

has been constructing so much first-class tonnage of recent years that it has been remarkable to see such ships as the *Tantallon Castle*, the *Dunvegan Castle*, the *Carisbrook Castle*, and the *Braemar Castle*, to say nothing of the more purely intermediate boats, coming out each with her single set of machinery. It was held by the successful firm of Fenchurch Street that for a long voyage with few calls the single screw was sufficiently handy for all practical purposes; whilst the great strength put into the engines, and the careful system of balancing adopted in the machinery, offered substantial guarantees against breakdowns. But when the constantly increasing size of their mail vessels passed the 9,000-ton limit, and when the H.P. rose to 10,000, it was felt that the time for subdivision had come, and the new vessels now completing for the Castle Line at Fairfield are both designed on the twin-screw principle. Thus of passenger lines claiming to any importance the P. & O. alone have the unenviable distinction of adhesion to the single screw.

COMPRESSED-AIR MACHINERY.

THE use of compressed air as a means for the transmission of power is becoming more generally used as time goes on, owing, no doubt, to the simplicity of installation, the convenience and universal presence of the medium, and, lastly, the non-existence of any difficulties with regard to the exhaust or to leaks in the apparatus such as exist in hydraulic systems.

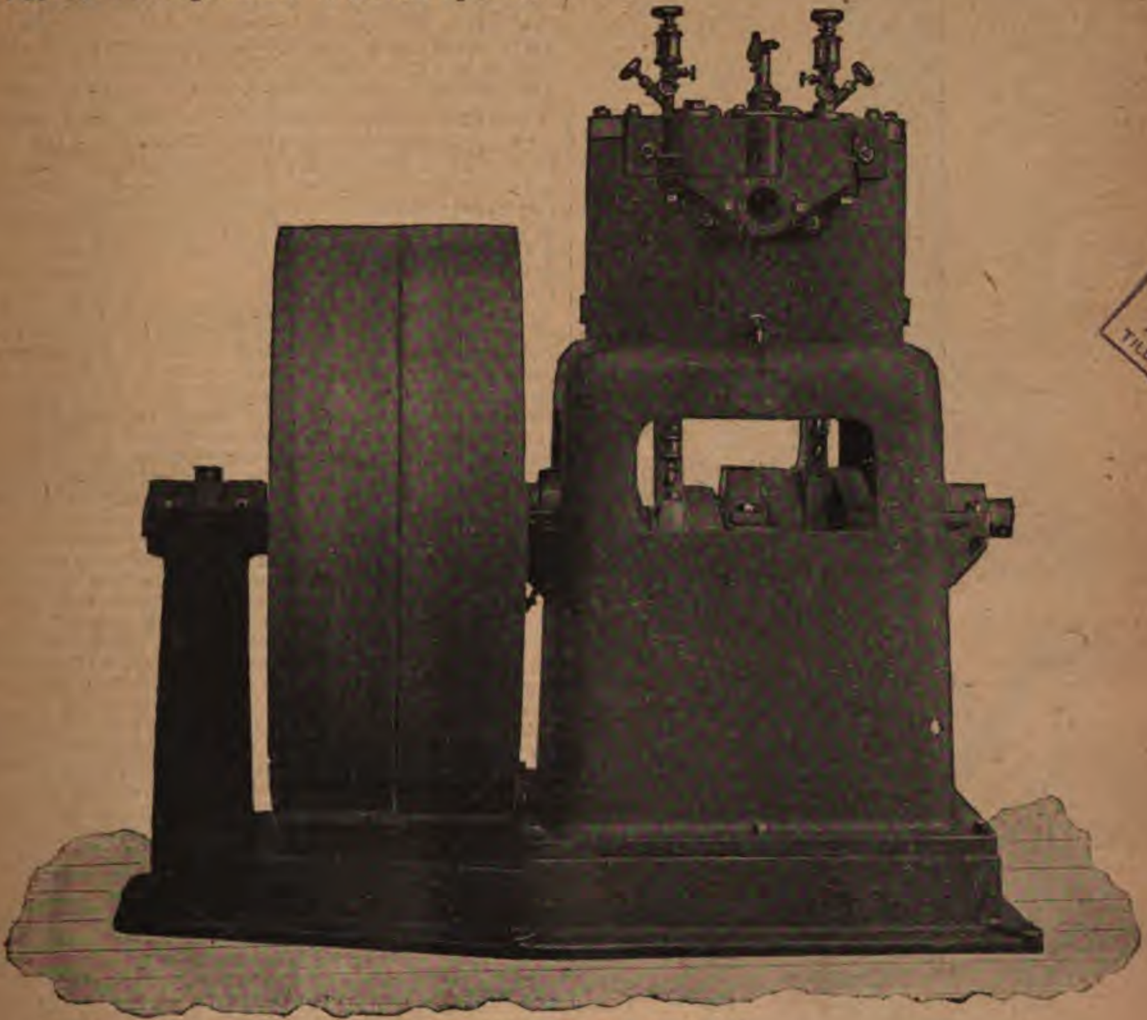
In the adjoining illustrations we show some of the compressed-air appliances which are sold by the United States Metallic Packing Co., Limited, of the Soho Works, Bradford, England. In Fig. 1 we show one of the single stage air-compressors for belt-driving. The cylinders, which are 8 in. in diameter and 8 in. length of stroke, are both single-acting, thus all stuffing boxes and crossheads are eliminated. The capacity at 120 revolutions per minute is 50 cub. ft. per minute, and at 100 lbs. terminal pressure per square inch these compressors absorb 9·2 H.P. Water-jackets completely surround the cylinders, cylinder heads, and valve cases. The cooling water enters through the valve case jacket, and passes thence through the heads and cylinder jacket; properly located partitions ensure a thorough circulation.

The valves are made of the poppet gravity type of phosphor bronze, and work without springs; they are located in a separate case. The discharge valves have renewable seats, and by removing a brass plug the valves can be reached without breaking any pipe connection or other joints. The valves are so constructed as not to break and fall into the cylinders. The pulleys are two in number, one loose and the other tight, the latter being formed heavy enough to act as a fly-wheel, so as to ensure smooth running and long life to the belt. The compressor is fitted with a governor, which is combined with the valve case, and is so arranged as to automatically maintain any desired air pressure. This is effected by stopping the compression of air without stopping the machine as soon as the pressure of air in the reservoir reaches a desired limit, and when the pressure has fallen one or two pounds it allows compression to commence again, so that work is only done when wanted, and no energy wasted as in compressors which have no governor, but only a safety valve on the reservoir. A further feature is that, by turning a small handle on the governor, the compressor can be started under no load; and, when the fly-wheel is in motion, the load can be thrown on, thus preventing undue strains on belts, shafts, &c.

In Fig. 2 we show an external view of the valve used on compressed-air installations for the control of the air to the recipient device. The valve is of the sliding type, and so tends to wear tight. There are no stuffing-boxes on it and it is self-closing by means of a spiral spring and bridle chains as soon as the hand chains are released. A safety check is provided on the valve, so that the load will not fall in the case of the air hose breaking. A speed adjustment is also fitted, so that a safe rate of hoisting or lowering may be ensured, irrespective of the amount of valve opening or load, so that a careless operator cannot cause accidents by raising or lowering loads too rapidly.

Fig. 3 shows an air jigger, or hoist, having a steel cylinder 15 in. in diameter and 5 ft. stroke. As in other jiggers, a wire-rope sheave is carried upon the outer end of the piston rod. The hoist here shown was made for attachment to the mast of a steel jib crane for use in a foundry. Of course, when convenient the lifting may be direct; that is, the cylinder may be hung by a hook to some overhead support, while the piston rod may carry a hook or other device to which the load can be readily attached. This latter forms a very simple arrangement, and is extremely convenient when short lifts only are required—viz., those within the range of the stroke of the cylinder. Such a self-contained device as this can be readily put up and taken down in a fitting shop to suit varying circumstances and jobs, all that is necessary being that some means be existent to attach or hang the hoist to. If rolled steel joists are available, a very simple carriage can be devised to roll on the flanges of the joists, to which the hoist cylinder can be depended.

There is, no doubt, a wide field of application for simple and convenient labour-saving machines, and it would appear that compressed-air devices should fill many wants in this connection.



Compressed-air Machinery. Fig. 1.

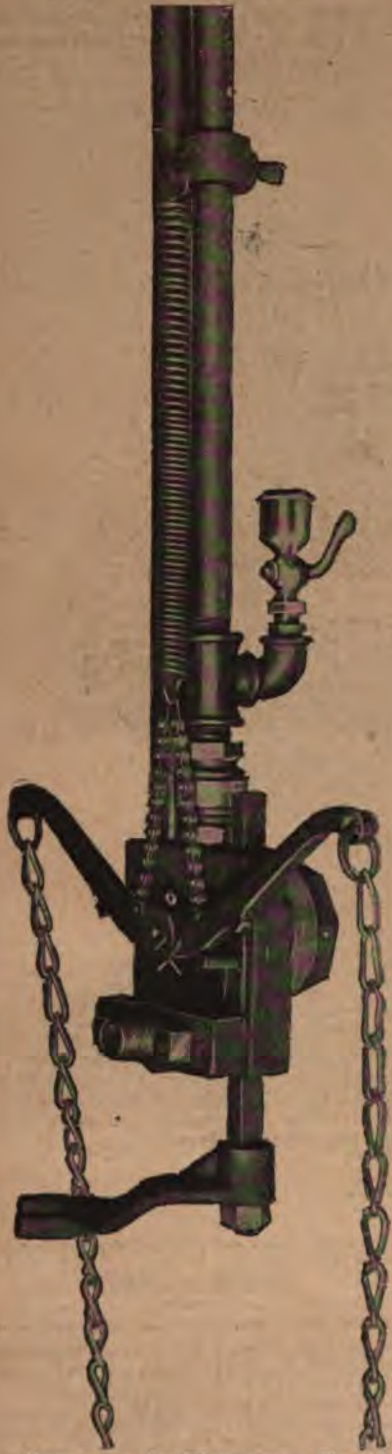
THE NEW PUBLIC LIBR ASTOR, LENOX AND TILDEN FOUNDATI

NAVAL MATTERS—PAST AND PROSPECTIVE.

(From our own Correspondents at home and abroad.)

The Training of the Engine room Department.

MR. C. M. JOHNSON'S ideas about the training of engine-room complements are all right enough up to a certain point, but when reading his criticisms one must remember that as regards the stokers they cannot learn their work ashore, and the same may be said of the young engineer officers, whom the retired chief inspector of machinery asserts are sent afloat devoid of any practical knowledge of their duties. The same thing could be said of the seamen-class. Everybody who is employed upon a battleship learns the practical part of his work there. Stokers might certainly undergo a course of training on board a ship specially adapted for the purpose; but this scheme was considered some years ago, but found little favour with the Admiralty. For practical purposes the system employed at present answers fairly well. A certain number of young stokers go to sea to learn their trade under a number of old stokers, and although the argument that it is unwise, and even dangerous, to allow untrained men to be sent afloat holds good to a certain extent, it must always be remembered that *they are* under the care of other stokers much older and with more experience than themselves. Mr. Johnsen says, "If these newly-raised officers and men were borne as supplementary to the official complement of the engine-room for the purpose of being trained, we might be thankful for the half loaf; but even then we should know that the instruction would be at best perfunctory and devoid alike of thoroughness and system." But it seems that whether newly-raised officers and men are borne as supplementary or otherwise, they are in the engine-room to be taught. It would not be wise to join issue with Mr. Johnson when he says that for the first two years of a commission, no ship is possessed of a full-trained engine-room staff, but he has omitted to say, that in every new vessel it is some time before the officers and men of the engine-room, whether all trained men, or part learners, become used to the machinery. It is certain, however, that if we can put trained men into the engine-rooms of every newly-commissioned vessel, it would be a great advantage, and if Mr. Johnson's letter brings about this happy state of affairs, then he is to be congratulated.



COMPRESSED-AIR MACHINERY. FIG. 2.

The Internal Construction of Torpedo Boats.

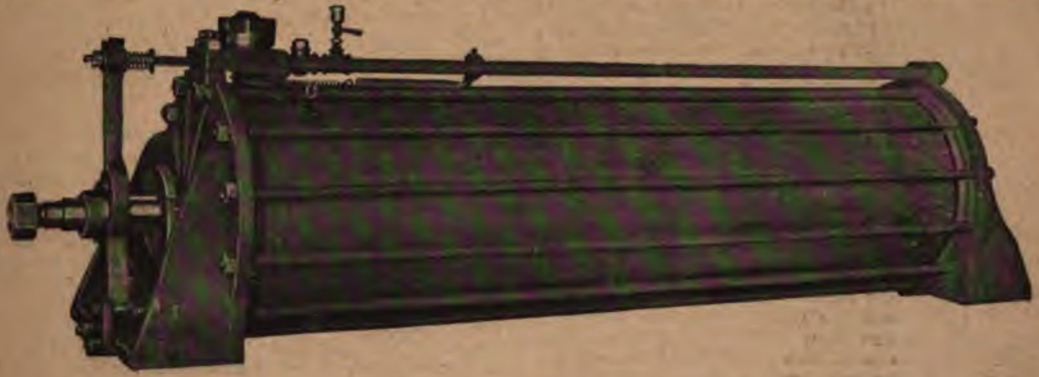
The attention which the United States Navy has received since the late war with Spain has resulted in schemes for the addition of warships of all dimensions, from torpedo-boat-destroyers upwards, to the Navy of that country. From news to hand from America it appears that considerable additions are to be made to the torpedo-boat flotilla, and therefore a paper submitted to the United States Naval Department by Lieut. Commander W. M. Kimball, in command of the North Atlantic torpedo-boat flotilla, on the subject of the machinery of torpedo-boats, has been read by the chiefs of the Naval Department with a good deal of attention. In the course of his paper Commander Kimball states, concerning American torpedo-boats, that the exact balance of the main engines cannot be too carefully attended to, and that connections should allow either engine to take steam from any boiler, both from main and auxiliary steam piping system. He considers that surface blows are desirable, for boiler water will get dirty in spite of all precautions. Coal bunkers abreast engine rooms, says Commander Kimball, give no real protection, because when trimmed for an attack they should be empty, to give the boat her speed. On account of the inaccessibility of the coal in them they would never be used except in long slow runs—so long and so slow that it would be much better to tow the boats than to steam them. There cannot be any properly constructed coal bunkers aboard torpedo boats, and the real solution of the difficulty is to resort to liquid fuel. The idea of engine protection by bunker coal is delusive; for not only should the engine-room bunkers be empty to put the boat in fighting trim, but even if some coal be in them it will provide no protection, for the things most needing protection are the steam pipes that must be placed high. Therefore, for torpedo boats Commander Kimball would run the engine rooms out to the side, and, if necessary for coal supply, fit thwartship bunkers. Commander Kimball may be right in the majority of his assertions, especially as regards the idea of engine protection by bunker coal. The use, however, of liquid fuel on board the *Surly* has not given the results which were anticipated, and therefore the difficulty he mentions as regards the coal bunkers is not likely to be solved yet awhile.

Devonport Dockyard.

Although the *Bulwark* has only been in hand since the 20th of March last, an effort is to be made to get her afloat by the end of the present year, and if this is done, this yard will have launched three battleships within 18 months, which will be a record. It is announced that the *Ocean* will be ready for sea on the 18th of August. It is 30 months since she was laid down. The announcement that Admiral Sir Henry Fairfax was to assume command at this yard on the retirement of Admiral Sir Edmund Fremantle was received with a good deal of satisfaction. Admiral Fremantle's jubilee of his connection with the navy will be reached on the 9th of this month, and he hauls down his flag, probably for the last time, amid the keen regret of everybody who knows him. Rear-Admiral Carr's connection with this yard, and the navy also, comes to an end this month; but he carries with him into retirement the respect and good feeling of all connected with Devonport. The refit of the *Melampus* has been completed, and the vessel despatched to Kingstown. The *Psyche* has also been made ready and sent on her first voyage to the North American Station. It is her maiden commission, and the fact that she was built, engined, and completed at this yard will cause a good deal of interest to be taken in her future career by all Westcountrymen. She is to replace the *Pallas*. The cruiser *Highflyer* has arrived here to be completed for sea. The cruiser *Blonde* has been commissioned after undergoing a refit, which cost nearly £9,000. The *Pique* has also been refitted at a cost of £10,000, and has completed her trials. The *Dwarf*, which has arrived here from Glasgow, is to prepare for commissioning as quickly as possible, and will probably be sent to the China station.

The Launch of the New "Victoria and Albert."

On the 9th of last month the third Royal yacht of the name of *Victoria and Albert* was launched from Pembroke Dockyard, H.R.H. the Duchess of York, performing the christening ceremony. Mr. Goschen, Sir William White, Admiral Sir E Fremantle, and Rear-Admiral Sir J. Fullerton, with others, were present at the launch, which was a most successful one, the new vessel taking the water in splendid style. A good deal of information about the vessel has been given from time to time in these columns, but in the circular given out to all newspapers who made application for it the Admiralty gave a good deal of additional news about the ship Compared with the present Royal yacht the new vessel has an additional deck, and the State deck is about ten and a-half feet above the water. Between it and the upper deck are situated Her Majesty's apartments and those of the Royal family, the cabins assigned to their suites, and those appropriated to the commanding officers and the principal naval officers attached to the vessel. The apartments of Her Majesty resemble in their general arrangement those in the old *Victoria and Albert*, but they are more spacious, and a private dining-room has been added. These rooms occupy the central portion of the State deck where the minimum of motion in a seaway should occur. The apartments of the members of the Royal Family are placed abaft those of Her Majesty, extending over a considerable length on the State deck. They are succeeded by the apartments of the Royal suite. Rather more than half the length of the vessel is occupied by these three series of apartments, and a wide corridor extends from end to end, with convenient staircases leading to the upper deck. Above the upper deck, towards the after part, is a large pavilion or saloon, besides reception and smoking rooms, and the top of the pavilion forms a promenade. It is hoped the new vessel will be ready for her steam trials towards the end of the present year, when she will leave Pembroke for Portsmouth. She is expected to be ready for service early in 1900.



COMPRESSED-AIR MACHINERY. FIG. 3.

Mr. Goschen and the Navy League.

The deputation from the Navy League, which waited upon Mr. Goschen the other week, did not meet with the reception which it is possible it expected, and as far as the First Lord of the Admiralty is concerned, state-aided training ships are not likely to be instituted yet awhile. The deputation may be said to be the outcome of the letters written by the novelist, Mr. Clark Russell to the *Morning Post*. The tone of these letters indicated that Mr. Russell thought that in case of war the Navy would get a bad licking unless it could get help from the merchant marine. This may have been partly true as regards the Navy of fifty years ago, but Mr. Goschen made it very clear indeed that the Navy of to-day was in no want of men, and not likely to be if war did break out. Mr. Clark Russell's knowledge of naval affairs was not deep enough for him to know that the personnel of the Royal Navy does not look to the Merchant marine for its war reserve. The scheme which the League proposed of state-aided training ships originated probably with Mr. Yoxall, M.P., and he was slightly incorrect when he asserted that the Reserve had not increased, and his statement that the Admiralty were embarrassed by the manning question drew from Mr. Goschen an emphatic denial. Mr. Goschen would not admit that the sources of the Naval Reserve were drying up, and said that the Board was well satisfied with the fishermen, a pleasing assurance to those who remember that in its infancy it was confidently asserted that the experiment would be a failure. The deputation finally withdrew, having accomplished nothing. It does not seem fair to the general public that merchant seamen should be taught their trade at the public expense, after having probably had a free school board education, and then turned over to the shipowners, who would reap practically all the benefit, although it is proposed that the Admiralty should be able to claim in time of war the service of these men. And yet, on the other hand, some scheme can surely be devised for ousting the foreigners from British ships.

Sheerness Dockyard.

The new cruiser *Pomone*, the last of the three cruisers of the "P" type to be completed at this yard, is now ready to take her place on the East Indies Station, under the command of Captain E. A. Simons, as the gunboat *Redbreast* is returning home. The *Galatea* has been completed, and has now departed for Iceland, there to protect the interests of the British fishermen. The *Partridge* has completed her refit, and has now left to relieve the *Magpie* on the Cape of Good Hope and West Coast of Africa Station. The appointment of Admiral Sir Charles Hotham, as Commander-in-Chief at the *Nore*, expires within the next two months, but the name of his successor has not been officially given out. The water-tube boilers for the new sloop *Rosario*, which are being made in the Keyham Steam Factory have not yet been delivered, but she is now quite ready for them. Her sister ship the *Condor* continues to make good progress, as do the *Sheerwater* and *Vestal*.

Temperance in the Navy.

Miss Agnes Weston certainly deserves her title of "the sailor's friend," and every seaman, whether of the engine-room complement or otherwise, must feel grateful to her for the services she has rendered the Navy during more than twenty-five years of her life. Miss Weston attended a meeting at Exeter Hall about a week back, and there said that there was a steady increase of temperance in the Navy. She pointed out, too, that she used the word temperance as meaning total abstinence. There are probably thousands of men in the Royal Navy who, although not quite total abstainers, are really temperate men. Miss Weston apparently thinks it quite sufficient if she can induce the men to be temperate without becoming total abstainers. In reviewing the work of the year Miss Weston mentioned the Royal summons to Windsor Castle which she received last year, and said that when shortly afterwards her Majesty sent her her own signed portrait from Osborne as a personal gift, she felt, as she wrote to the Queen, that not only would it be treasured as an heirloom, but that when tired and dispirited she should look at it and gain fresh strength by remembering the kindly interest shown by her Majesty. She also mentioned that a naval officer of high rank had come over from Germany to enquire into the methods of working adopted at the Rests with a view to commencing the building of similar institutions in Germany. A naval attaché of the United States had also visited the Portsmouth Rest for the same purpose. Miss Weston, it may be added, has received the £5,000 she asked for as a silver wedding present for Portsmouth, and she stated that she felt quite sure she would get the £10,000 she had asked for the enlargement of the Devonport Home.

Lord Charles Beresford and the Engineers' Grievances.

The speech made by the ubiquitous Lord Charles Beresford at the annual dinner of the Institution of Mechanical Engineers was extremely non-committal, and yet it showed that the noble lord was desirous of cultivating a good opinion of the naval engineers. He considered, and quite properly, that any complaints should be placed before the proper authority, and he further considered that a Departmental Committee should be formed to enquire into the matter. By going to the engineers themselves for information Lord Charles discovered what everybody else has been cognisant of for more than a year, that the engineers wanted "executive rank, the curl on the arm, and the power to inflict minor punishments." In his opinion the number of engineers was too small. A ship should be as near as possible self-supporting. If there were not enough expert engineers in the ship, the repairs could not be carried out. All complaints which reached the authorities should be threshed out, and they should show that it was either a just complaint or an unjust complaint, whilst a Departmental Committee should be appointed at once. The pros and cons of this question have been considered over and over again, and it would be useless to reopen the question at the present moment; but, if Lord Charles Beresford has any influence at Whitehall or in Parliament, he will earn the everlasting gratitude of the naval engineers if he will use it to get a few of their grievances redressed.

Pembroke Dockyard

The chief event of the month at this yard was, of course, the launch of the new Royal yacht. It is proposed to spend upon this vessel, during the current year, £104,245, more than £33,000 of which is for labour, and nearly £23,000 for machinery. It is noteworthy that there are still a few individuals employed at this yard who were working here in January, 1855, when the old *Victoria and Albert* took the water. The new first-class cruiser *Drake*, which has now been in hand five weeks, makes fair progress, and the number of tons of material worked into her up to date gives a very good average considering that the number of hands employed upon her is not quite as many as could be wished for.

The United States Navy.

One result of the war waged with Spain by the United States is that a great demand has arisen for the presence of United States' warships in different parts of the world—a demand which the Navy Department has not found it easy to meet, despite the fact that every available vessel is being commissioned, and new ships completed as fast as possible. There are now fleets in the Philippines, West Indies, and the North Atlantic, and there is to be a squadron in the South Atlantic, of which the *Wilmington* is already on the station, and the *Chicago* on her way out. Of the ships now on the stocks, the *Kearsarge* and *Kentucky* will be ready for service in a month or so; and as regards the other ships, their state of advancement works out as follows:—*Illinois*, 64 per cent.; *Alabama*, 80 per cent.; *Wisconsin*, 65 per cent.; and the cruiser *Albany*, 80 per cent. The battleships *Maine*, *Missouri*, and *Ohio*, and the monitors *Arkansas*, *Connecticut*, *Florida*, and *Wyoming* are not yet in hand. The torpedo-boat destroyers are none of them far advanced, but several of the torpedo-boats will very soon be ready for commissioning. Tenders for armour for the *Maine*, *Ohio*, and *Missouri*, and the four monitors mentioned have been asked for, but the price must not exceed £80 a ton—the sum fixed by Congress. With the armour required for the battleships *Pennsylvania*, *New Jersey*, and *Georgia*, and the armoured cruisers *West Virginia*, *Nebraska*, and *California*, about 24,000 tons in all will be wanted; but there is a little doubt as to whether the leading armour-makers will submit to bids at this price. If they will not, the matter will have to be reconsidered by Congress.

The Scylla's Gunnery Practice.

Captain Percy Scott, commanding the cruiser *Scylla* in the Mediterranean, has earned the thanks of My Lords of th Admiralty. If any member of the House of Commons now dares to hint that we are behind other Powers as regards gunnery, Mr. Goschen has only to mention that the *Scylla*, when recently employed in the Mediterranean, achieved the highest record at prize firing ever attempted. The remarkable shooting in question took place on the occasion of the annual prize firing of the *Scylla* in the Mediterranean. Steaming at twelve knots, seventy rounds were fired at a target 1,600 yards distant, and fifty-six direct hits were recorded, or eighty per cent. of successes. At a dinner given by the petty officers of the ship to commemorate the approaching termination of the *Scylla's* commission, the vice-chairman said that this record of straight shooting had never been approached before, and was not likely ever to be beaten. Replying to this, Captain Percy Scott said: "As regards your success in straight shooting with heavy guns in the prize-firing on Wednesday, I believe the statement that the score of 80 per cent. is a record to be absolutely correct, and it gave all the officers and myself very great pleasure to see it, although I fully expected you to reach 90 per cent. I only hope, however, that if you are ever called upon to fire at an enemy, you will knock him about as much as you did that target. Straight shooting with heavy guns is the most important part of a sailor's education, and you cannot pay too much attention to it. An action of the future will be decided—and quickly decided—by the straightest shooting, and it is upon the men behind the guns that the nation will have to rely." Of course, one swallow does not make a summer, and the remarkable prize-firing made by one British cruiser does not prove that the gunnery of the British Navy is superior to that of every other navy. However, there is no reason that it should not be if every captain gives a proper amount of attention to the Admiralty Gunnery Practice circular just issued.

Chatham Dockyard.

The chief work at this yard appears to be the fitting out of vessels for the manœuvres, which are to commence in July. The *Sappho* has been taken in hand to have some defects seen to, and the *Vindictive* has also gone into dock to be prepared for sea. The *Tribune* has had a final overhaul of her under-water fittings, and is once again afloat, as is the *Endymion* The trials of the *Diana*, which are to consist of three trials of thirty hours' duration each, the first at 1,600 I.H.P., the second at 4,800 I.H.P., and the third at 6,400 I.H.P., have now commenced. An eight-hours' trial at 8,000 I.H.P. is included. The basin trial of her engines was most satisfactory, as were the experimental steam trials to test her consumption of feed-water. The defects of the *Grasshopper* have been attended to, and she has been undocked, and the *Slaney* has taken her place. The torpedo-boat destroyer *Spitfire* is also being prepared for sea. The repairs and alterations on the *Mersey* make good progress, and an effort is being made to get the *Sanspareil* ready to take part in the manœuvres. The *Dreadnought*, which has been in hand for the past twelve months, is now ready for sea. She has received a new armament and a new set of boilers, and her hull and machinery have undergone a thorough repair. The *Endymion* and *Astræa* are to hoist the pennant this month, and all defects on these vessels are now being attended to. The *Goliath* is to be ready for the pennant by September, her trials taking place at the end of this month, or at the beginning of next. The cruiser *Pioneer*, which was laid down on December 16th, 1897, is now ready for launching. Although she has been what is now regarded as a long time in building, she will be practically completed when she takes the water, and her steam trials will take place very shortly after this event.

The New Royal Naval College.

Work on the site on which the new Royal College is to be built, at Mount Boone, Dartmouth, is being actively carried on, and the architect, Mr. Aston Webb, A.R.A., recently visited the place himself to see what progress was being made. The Mount Boone estate is about 200 ft. above the river Dart, and the building which is to be erected on it will provide accommodation for 260 cadets and staff. The educational buildings form the central block, and contain a large hall, 90 ft. by 50 ft., with two floors of class-rooms on either side. On either side of the central block are the dormitory and day-room blocks, each block for 130 cadets. On the north side of these blocks are sanitary blocks. The block at the western end contains the cadets' dining hall, 80 ft by 40 ft. On the south side of this block, and towards the view, are the officers' ward, the mess-room, &c., with kitchens and stores complete. On the north side are the various mess-rooms for the petty officers and staff. The corresponding block at the other end of the building contains the captain's house, also with a southern exposure towards the view, and a chapel to hold 350 persons. The whole building, which has a southern frontage and a beautiful view towards the mouth of the Dart, is arranged in semi-detached blocks to secure ample proportion of air round each block. Sick quarters, with sixty beds, will be built to the west of the site, consisting of infectious and non-infectious blocks, an administrative block, doctor's house, and quarters for the infectious nurses. Some thousands of pounds have already been spent upon the place, and when the building is finished it will be one of the finest of its kind in England, although it has been suggested that it might have been built to hold a larger number of cadets.

The Work of the Navy Employment Agency.

The third annual statement of the affairs of the Navy Employment Agency forms very satisfactory reading. The Agency, which, it will be remembered, is carried on under the control and management of members of "The Castaways" Club, was instituted some three years ago for the purpose of finding employment for seamen who had left the Navy. A branch office has recently been opened at Portsmouth. The names of 1,063 applicants for assistance have been placed on the book since the agency has been instituted, and during the year ending March 31st last 250 men have found employment, an increase of twenty-two over that of the previous year: and indirectly the agency has found employment for from 130 to 380 men, which is also an increase on the previous year; 109 men are still on the books as unemployed. However, taking various conditions which prevailed during the two years into consideration, the committee are of opinion that the work is increasing in a marked degree. There is one point which cannot be too strongly impressed upon men seeking employment, namely, the harm done to the agency by men who throw up a billet before they have given it a fair trial, in some cases for very trivial reasons. This, in nine cases out of ten, has the effect of depriving the agency of the patronage of the employer who is thus treated, and so closes a channel of employment to other men. With regard to the finances of the agency, the committee have invested a further sum of £100 in the Post-office Savings Bank. The donations this year are £267 7s., as against £224 10s 7d. in the last report, and the annual subscriptions £152 18s. as against £105 14s.; a very gratifying increase. This invested capital is intended to be kept as long as possible as a provision for contingencies, and the committee do not propose to add to it further, but to expend any surplus funds towards extending the scope of the agency. The appeal for increased support ought not to be made in vain, for, if similar branches were established in other naval towns, much good would certainly result. The agency is willing to do its best to find employment for men of the engine-room complement, as well as of the seaman class.

Portsmouth Dockyard.

The *London* and *Pandora*, which are under construction at this yard, continue to make fair progress, but the completion of the *Gladiator*, *Canopus*, *Formidable* and *Andromeda* occupies the most attention. The progress of the work of completing the *Canopus* is somewhat slow, but practically the whole of her armour has been fitted. It was intended, if possible, that her trials should take place some time this month, but no date has as yet been fixed. There is very little other news to record except that the torpedo-net cutter, invented by the officers of the *Vernon*, has proved so successful that they are now turning their attention to the invention of a net which shall resist this cutter. The next step will probably be to invent a new cutter to break through the meshes of the new net when it is invented. Another invention from the *Vernon* is a cutter to sever the 6-in. wire hawser which forms part of the boom devised by the *Vernons* some time ago. About refits, it may be mentioned that the coastguard and portguard squadrons are this year to undergo a three months' refit, and that the defects will not be glossed over in the old sweet way. After this thorough overhaul, however, they are to be kept in such a state of efficiency that only a month will need to be spent upon their annual refit. The condensers of the *Trafalgar* are said to be completely worn out. An item of news that may interest many is that the band of native musicians which were employed on the *Renown* in the West Indies did such satisfactory work that they have been turned over to the *Crescent*, and are to serve another commission in her.

Our Naval Superiority.

The introductory article, contributed by Lord Brassey in the "Naval Annual" for 1899, will afford food for reflection for the naval "experts" of both France and Russia—if the latter country has any gentlemen of this profession. Lord Brassey says that if we compare the fleets in commission under the French and British flags, it will be seen that, both in the Channel and Mediterranean squadrons, in battleships the British fleet has an overwhelming superiority, while in cruisers we far outnumber the ships under the French and Russian flags. Lord Brassey sums up the official table of the comparative strength of the world's navies, and in doing so points out that the full superiority of the British Navy is not properly shown in a comparison of numbers without reference to dimensions. We have 24 ships of over 14,000 tons; 11 of between 12,000 and 13,000 tons; 10 of between 10,000 and 12,000 tons; 17 of from 6,500 to 9,100 tons; 24 of from 4,000 to 5,800 tons; and 46 of from 2,000 to 4,000 tons. Taking the ships of even date with the British, France has 11 of 11,000 to a little more than 12,000 tons, while Russia has only 9 ships of more than 11,000 tons. It is pretty well known that a French battleship of the same tonnage as a British battleship will cost a good deal more money, and, according to Lord Brassey, the difference is nearly £150,000. He also calculates that, although our cruisers of from 11,000 to 14,000 tons cost from £500,000 to £700,000, cruisers of inferior tonnage built for foreign navies cost from £800,000 to £900,000. Figures will prove anything, and it is a question whether it is advisable to make out in this way that we have such a great superiority over the navies of France and Russia. However, Lord Brassey's article is well worth reading, if only as an antidote to the alarmist letter sent round to the Press by the Navy League.

Building Up the French Navy.

The ridiculous manner in which the French Anglophobe organs have attacked the French Government for allowing Captain Jackson, the British naval Attaché in Paris, to pay a series of visits to the French naval ports, only goes to prove how slight their knowledge is of naval affairs. One would not think that a reasonable man would suppose for one moment that Captain Jackson, if he wished to unearth French naval secrets, would openly go down to the dockyards for the purpose. Practically anybody can get a permit to go over the French dockyards much in the same way as the English dockyards can be visited, and a statement of the number of vessels building in France with their dimensions is published every now and then in the local papers. At Cherbourg there are several vessels on the stocks or being completed. Among them are the *Henri IV.*, an ironclad of 12,700 tons, the submarine boats *Morse* and *Narval*, and the destroyers *Dunois*, *Fleurus* and *Lahire*; while at Brest the *Charlemagne* and *Gaulois*, of 11,200 tons each, and the *Iena* of 12,000 tons are being completed, and the cruiser *Suffren*, of 9,000 tons, is on the stocks. At Lorient the first-class cruiser *Gurrien-de-la-Graviere* and the gunboat *Decidee* are to be launched in June, and the cruiser *Gueydon*, of 9,500 tons, in September. The battleship *Saint-Louis*, 11,300 tons, is being pushed forward, in order that her trials can be made in the same month. As soon as the launches mentioned take place, two cruisers of 10,000 tons each are to be commenced. At Rochefort there are in hand the cruiser *Dupleix*, 7,700 tons, the *D'Estrees*, 2,500 tons, the *Protet*, 4,100 tons, and the gunboat *Zelee*; the last two are being prepared for sea. The armoured cruiser *Dupetit-Thouars* and the *Jeanne D'Arc*, of 11,300 tons, are in hand at Toulon, while there are six armoured cruisers of from 8,000 to 10,000 tons, a third-class cruiser, fourteen destroyers, and thirty-two torpedo-boats being built in the private yards.

The Edwards Air Pump Syndicate, Limited.—Owing to the growth of the business of the Edwards Air Pump Syndicate, Limited, and to Mr. Edwards requiring the whole of his offices for his practice and research purposes, the directors of the syndicate have provided the company with offices at 3, Crown Court, Old Broad Street, E.C. One of Mr. Edwards's assistants, Mr. Frank L. Rowe, has been appointed manager of the company, and correspondents are asked to address all future communications to the syndicate at Crown Court. Although the business is no longer conducted at Mr. Edwards's office, he is still managing director of the syndicate, and its business remains, as before, directly under his personal supervision.

THE NEW ROYAL YACHT "VICTORIA AND ALBERT."

ON the 9th of May the new Royal yacht, *Victoria and Albert*, was named and launched by H.R.H. the Duchess of York. The Duke of York was, unfortunately, unable to be present owing to indisposition, and the Duke of Connaught accompanied the Duchess of York instead. This vessel, which is from the designs of Sir William White, Director-General of Construction, was laid down at Pembroke Dockyard in the latter part of 1897. It is an interesting point to note that this is the third Royal yacht built at Pembroke during the last sixty years.

The present *Victoria and Albert* was launched at Pembroke in 1855; her length between perpendiculars is 300 ft.; length, over all, 338 ft.; breadth, 40 ft. 3 in.; mean draught, 16 ft 3 in.; and displacement, 2,470 tons. She is, as probably most people know, a paddle boat, and is fitted with engines of 3,000 I.H.P., made by Messrs. Penn, of Greenwich, which propel her at about 15 to 16 knots per hour, and in her early days she attained 16¾ knots per hour.

We have given these few particulars so that the present yacht may be compared with the new one that has just been launched. In the first place, she will be a radical departure in the matter of propulsion, twin screws being provided for this purpose. Her length between perpendiculars is 380 ft.; length, over all, 439 ft.; breadth, 50 ft.; mean draught of water under normal conditions, 18 ft.; displacement, 4,700 tons; and the maximum I.H.P. is 11,000. In the notice we gave of this vessel in our issue of January, 1898, we stated that special care was being taken to make the vessel very comfortable in every way, and at the same time to give her a reasonable speed. We believe that it is contemplated that her sustained sea speed in fair weather will be about 17 knots, and that she is to be capable of 20 knots on the measured mile trial of eight hours. Her coal supply is to be about 2,000 tons, which should be sufficient to steam from England to Malta at a speed of about 14 knots.

The engines, which are triple-expansion, consist of two sets of vertical inverted type, each set comprising four cylinders, and the moving elements are balanced according to the Yarrow-Schlick-Tweedy system. This latter provision has been adopted to reduce vibration in the vessel to a minimum. Each set of engines is to be placed in a separate water-tight compartment. The steam will be supplied by eighteen boilers of the most approved Belleville pattern, fitted with economisers in the uptake. There will be two stokeholds in separate water-tight compartments, each containing nine boilers. Special attention has been paid to the ventilation of the machinery and boiler departments.

A very complete electrical installation is to be provided, which will provide energy for lighting the whole of the ship, for working lifts, pumps, hoists for boats, ventilating fans, the after-capstan, and heating the principal apartments. It is anticipated that, by substituting electricity for steam in these auxiliary services, very great comfort, as well as high efficiency, will be obtained. The vessel will have a clipper bow, an elliptical stern, three tall raking masts, and two funnels; her hull is constructed of steel, sheathed with teak and copper, the teak sheathing being carried up to the upper deck and the copper sheathing to a little above the water-line.

The wood used in the bulkheads, fittings, and furniture is to be treated by a special chemical process to render it practically uninflammable.

The interior of the vessel is divided into a large number of water-tight compartments, and the hull has a cellular double-bottom extending from bilge to bilge; the double structure being practically extended up to and above the water-line by the coal bunkers.

The upper deck is 19 ft. above the water-line, and the State-deck about 10½ ft. More than half the length of the vessel on the State-deck is taken up by the apartments for the Queen, the members of the Royal family and their suites, and also for the commanding officer and principal naval officers attached to the vessel.

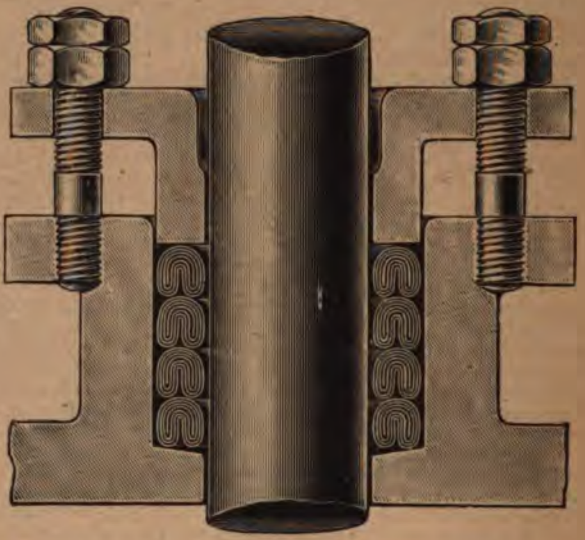
The sanitary arrangements have had special attention bestowed on them, and hot and cold water supply will be fitted in the bathrooms and principal sleeping cabins.

All the spaces on the lower deck which are for the accommodation of people, are provided with special ventilating side-scuttles capable of giving light and air under all circumstances, even in bad weather.

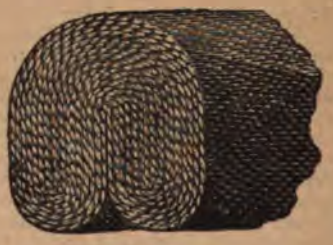
The vessel will be brought round to Portsmouth, when the machinery has been fitted and is ready for the steam trials, on the completion of which the furnishing and decoration of the yacht will be taken in hand by Messrs. Waring.

PLATTS & LOWTHER'S PATENT COMPENSATING SPLIT PACKING.

IT is a matter of common knowledge among engineers that much power is wasted through the medium of tight packing, also that under such circumstances the packing and rod wear rapidly away by reason of the friction set up between them. Many engineers have had the experience of practical evidence of this fact in case of an engine when newly packed refusing to stir even under the full boiler pressure.



We illustrate in the adjoining diagram a gland fitted with Platts & Lowther's patent compensating split packing, which we understand is the result of many years' practical experience in the direction of obviating the disadvantages above enumerated. It will be seen from the illustration that the packing consists of two or more layers in close contact with each other in a U form. The rings of packing are placed one above the other in the stuffing box in the usual manner, as shown in the illustration. This arrangement produces an element of considerable elasticity, which gives a tight sliding joint with a minimum of friction. The packing also possesses a compensating property, for, as the layer next to the rod wears, it is caused by the pressure of the gland and the wedge action of each layer of



packing on the next layer to be automatically replaced by fresh material, and in this manner a large portion of the body of the packing is thus utilised.

A feature in the use of this packing is that very little pressure is needed by the gland on the packing, in fact the nuts only need screwing down by the hand without the use of a spanner, which is due to the extreme elasticity of this packing.

This packing is, we understand, being used largely in Russia for high steam and hydraulic pressures, and from the copies of the testimonials we have seen it appears to be very satisfactory and highly appreciated. As an example we would refer to the case of some new blowing engines which were packed with this packing and after four years' constant running, night and day, the tools' marks were still visible in the rods, which is excellent evidence of the absence of friction between the rods and the packing.

This packing is put on the market by Messrs. Platts & Lowther, of 23, Lime Street, Fenchurch Street, London.

MARINE ENGINEERS' NOTES.

(From our own Correspondent.)

THERE have been three papers read before the Institute of Marine Engineers during the month. The discussion on Mr. Nicholl's paper was finished at the previous meeting, and another on the comparison of the performance of two ships. This latter paper contained a great deal of data, but it could not be said that a comparison could readily be made, as neither the dimensions of the vessels, the lines were not the same. The H.P. required for each was very different. But one advantage of such a paper is very clear. It gives a record of what goes on in a voyage, and it is the kind of information which is interesting to marine engineers, and it also enlightens outsiders as to what goes on in a ship.

Mr. Lawrie was in the chair, and he expressed regret at the absence of Mr. Adamson, the honorary secretary. The paper was one which might be approached from a good many points of view. Mr. Halliday said at the beginning of the session he ventured to urge the desirability of obtaining papers from chief engineers of sea-going steamers in order that they might get detailed and reliable information as to what actually took place in the working of marine engines at sea. This was a paper that might not be of so much interest to the sea-going members, but to him and others similarly situated it was a paper of extreme interest and importance. More papers of the kind describing exactly what went on at sea would, he thought, be an excellent thing for the institution. Mr. Boyle remarked on the enormous difference in the results shown by the two steamers dealt with in the paper. The paper which came after this was also of some interest, since it settled several doubtful points which were raised in the discussion on water-tube boilers and feed-heaters. It will be remembered that one of those points was the effect of the velocity of the water through the tubes on the co-efficient of absorption of heat. Experiments have now been made on this point, and the results published in another part of the paper. The apparatus used was made very simple in order that the experiments could be performed by anyone else easily. But although the apparatus was made very simple, the results came out very satisfactory indeed. This simple apparatus easily showed that there is an increase of absorption of heat when the velocity of the water through the tube increases. But with steam where the heat cannot get quickly enough forward to the tube to supply heat as fast as the water in the tube can carry it away, it is different. There soon comes a point where there is a maximum absorption of heat, and then a rapid falling off as the velocity increases. But this maximum point depends on the kind of fire which is heating the tube. If a fierce fire, then the maximum point will be at a high velocity, and if less fierce the maximum point will come sooner. In one case the maximum point came at a little over a point which represented a velocity of 100. In another case it was nearer 150, and in still another case the maximum point came where the velocity was a little over 150.

There was another question which required solution. That was the question of the properties of the water just at the boiling point. It has been held by some that when water reached the boiling point it immediately developed new properties which enabled it to absorb heat at a much higher rate. Some experimenters, notably the French, held that at the boiling point a great increase of absorptive power took place, and M. Normand, before the Institute of Naval Architects, said that at this point the water absorbed three times as much heat as it did at other temperatures. The experiments made at the Institute of Marine Engineers to determine this question do not bear out the statements made by M. Normand or his French friends. A straight tube was taken through which the water could flow and boil, and it was arranged that the water should overflow from the tube and produce no circulation by currents in the tube; by this means any extra influence which the entraining action of the steam would have to produce more rapid circulation and more absorption of heat was prevented. When this was done, and bubbles of steam were freely given off at a temperature shown by the thermometer at 212 deg., with a circulation through the tube of 19·4 cubic centimetres per minute, the water absorbed 3113·7 thermal units. The trial was then made with the water running at a slightly higher velocity, just sufficiently high to stop the steam bubbles being formed. When this was done the temperature of the water fell to 202 deg., the average quantity of water flowing through the tube was 26·43 cubic centimetres per minute, and the number of thermal units going into the water as it flowed through was 3933·6 as against 3113·7 thermal units at the boiling point. Of course, the vessel used by the French experimenters was not suited for the experiment, as the effect of the circulation produced by the entraining action of the steam was not excluded.

The apparatus which is being made for new experiments is one which will first boil water in a vessel, and then allow it to flow into a second, where it will again be heated and kept at the boiling point. While kept at the boiling point it will circulate through this second vessel and be kept at the boiling point for a specified time. The first apparatus, presented by Mr. Hallett, has been on exhibition in London, and has been seen by eminent engineers with much satisfaction.

There are still further experiments to be made on the question of absorption of heat by water. Experiments have already been made by Mr. Hagemann, of Copenhagen, which are of some value, but they were made on different lines. And although his results would show that there would be a maximum point of heat absorption, he has not carried them far enough to demonstrate this point. It will be interesting to use a metal tube with gases playing on and the water moving very rapidly through it. Of course, the velocity at which the point of maximum absorption takes place will be very much higher, and there may be several other interesting points which the experiments can alone elucidate.

A very important series of articles has appeared in the *Engineer* on the naval boiler of the future. The last of the series is on the fire-tube boiler. As drawn it is of A shape with the fire between the legs. Water comes down the legs and through the legs of the A go fire-tubes at right angles to the sides. The hot gases thus flow through the tubes and ascend to the uptake from each side. The disadvantage of the fire-tube boiler, we are told, is that it is too heavy, due to its shell. It also carries too much water. It compares well, however, with the Belleville boiler, and a quotation is made from Herr Benischke on this: "Worked with all the care and attention necessary for the elaborate system described above, Belleville boilers have stood well at sea when not pushed, but as steam producers their results are not eminently good. What they save in weight of water, as compared with other water-tube boilers, is almost made up for by the weight of masonry in the furnaces, as well as of the feed air-compressing and steam-drying arrangements. At the trial trip of the Messageries Maritimes Co.'s *Australien* only 19·2 H.P. was obtained with one ton weight of boiler, whereas Scotch boilers produce 18 H.P. per ton with natural and 20 to 25 H.P. with forced draught." H.M S. *Hannibal's* Scotch single-ended boilers weigh 132 lbs. per I.H.P., and give 14·8 H.P. per square foot of grate. The Belleville boilers in the *Canopus*, working under similar conditions, weigh 103 lbs. per I.H.P., and the H.P. per square foot is only 12·9. The H.P. of the *Canopus* is about 21·7 per ton. Mr. Howden has obtained 25 H.P. per ton. The weight per square foot of grate of a Scotch boiler is given by M. Bertin as ·85 ton, of the Belleville ·53 ton, and of the Niclausse ·466 ton.

In the proposed fire-tube boiler which the *Engineer* gives in sketch the fire-tubes are 1 ft. 6 in. long and 1¼ in. outside diameter. And the argument is, the first inch or two of tube give as much evaporation as the last foot or two. They propose to set 36 tubes in a square foot of surface. The side is taken 7 ft. long, and its width 4 ft., so that on each side there are 28 square feet available. This gives 1,008 tubes, or 2,016 tubes in all. The spaces between are ¾ in., which is quite sufficient in a locomotive boiler using bad water. The area of each tube is ·5 square feet, and the total area 1,050 square feet of heating surface of maximum efficiency. The grate surface is about 30 square feet, and the ratio of heating surface to grate area about 35 to 1. They go on to say, "The Belleville generator is not to be the naval boiler of the future; it is a stop-gap, and nothing more." The articles close with an extract from Sir John Durston's paper: "The battleships have been tried with tank boilers. . . . and are all arranged to develop 10,000 I.H.P. with natural draught, and 12,000 I.H.P. with accelerated draught. . . . All these battleships obtain their maximum power by forced draught, fitted on the closed stokehold system, with the exception of the *Magnificent* and *Illustrious*, where fans in the uptakes are fitted on the system known as induced draught. The amount of forcing as indicated by the air pressure or vacuum required is but moderate, and the maximum powers were easily obtained. The boiler tubes are all fitted with the Admiralty cap ferrules, and leaky boiler tubes, once so fruitful of trouble in warships, are now practically unknown."

If numbers of attendance show success, then the address given by Sir William White at the opening of the session of the Mechanical Engineers was a great one. The subject was the connection between mechanical engineering and modern shipbuilding. Sir William made a division of his subject under several heads, such as steering, capstans, windlasses, and cable gear, &c. Under steering, the palm of efficient steering gear was given to Mr. Macfarlane Gray. The first steps were taken by Mr. Gray in 1866, as the result of difficulties that had occurred in steering the *Great Eastern*. Mr. Gray's invention of the differential gear enabled the steering engine, when placed at a distance from the navigating station, to be controlled by the movement of the steering wheel, so that the helm could be made to follow and assume any desired position. The successful trial of the *Great Eastern* led to the general adoption of steam-steering gear. The Admiralty took it up, on the advice of Sir Nathaniel Barnaby, and applied it to the *Minotaur* class. With manual power 18 men were employed at the wheel, and 60 at relieving tackles. They took one and a-half minutes to put the helm over to 25 deg., and seven and two-third minutes in turning the ship through 360 deg. With steam-steering gear two men at the wheel put the helm over 35 deg. in 16 seconds; the ship turned in five and a-half minutes, and in two-thirds the space.

ELECTRICAL NOTES.

(*From our own Correspondent.*)

THE United States army transport *Hooker* No. 1 is being fitted as a cable ship for service in the Philippine Islands. These islands are to be connected by the United States Government by cable, and about 240 miles of it will be sent out by the *Hooker* about May 1st. Nearly all the interior fittings of the ship have been removed, and three tanks for cables installed, also refrigerating rooms and appliances for the transport of fresh meat. The forward cable tank is 13 ft. in diameter and 8 ft. high, and has a capacity for 60 tons of cable. The midships tank, 24 ft. by 13 ft., has a capacity for 400 tons, and the after tank, 26 ft. in diameter and 6 ft. deep, will contain 240 tons, the total capacity being 700 tons of cable. The tanks are built of boiler iron with cabled joints, so as to be watertight. When the cable is coiled in place it is covered with sea water to serve as an outside connection, and to preserve the cable, which deteriorates rapidly when exposed to the air There is a winding gear fixed on the deck forward, which consists of a drum about 8 ft. in diameter, supplied with brakes and the usual accessories for cable work. Under the pilot-house is the cable testing room, fitted with galvanometers, in constant connection with a small battery and the cable; there are also fitted Wheatstone bridges *and* Kelvin marine galvanometers. The refrigerating plant can suit 150 quarters of beef, and the ship will thus be of use as a supply ship. The electric light plant consists of two 175-light units, each composed of a dynamo direct-coupled to an engine. The *Hooker* will have a cruising speed of 13 knots. She is 333 ft. over all, 33 ft. beam, about 2,000 tons burden, and has an engine of 1,600 I.H.P. for working a single screw. The forecastle has been heightened about 6 ft., herein are mounted two Hotchkiss six-pounder rapid-firing guns, to deal with the pirates of the Sulu seas, and 75 stands of arms are also carried. The officers and men number 150.

As early as 1833 Jacoby had an electric boat running in the Neva at St. Petersburg. It was very crude. There were primary batteries and an old rotary motor. Things have advanced since then. A very good and efficient electric-motor-driven launch has been fitted out in the United States lately. The motor is fitted in abaft the after bulkhead, which leaves the seat space entirely free of obstruction. There is no unseemly chimney shown, and no heat shows dangers of fire and explosion like those which accompany the steam and oil engines. Another advantage is that one man can run the boat himself. The control is effected by grouping the battery in various combinations. The controller axle projects through the hollow shaft of the steering wheel, and terminates in a small hand wheel directly in front of the steering wheel. When this hand wheel is moved in one direction, the boat goes ahead; when in the other direction, astern. There is a ball bearing thrust block in one of its journals, and the whole structure is watertight below the shaft line. There is no gearing—connection of the motor is made direct to the shaft through a split coupling. The storage battery consists of elements in hard rubber cells, having a special watertight cover to keep out the sea. The cells are collected in porcelain blocks, air spaces being left between the cells.

Wireless telegraphy, which appears destined to be of such service to the mercantile marine, is not so new as people would suppose. So far back as 1831 James Bowman Lindsay, of Dundee, actually conveyed messages across the Tay river. Lindsay was a weaver. But he had the gift of study so common to the humble Scotchman, and became ultimately a science teacher. In 1835 he showed an electric lamp in Dundee. His method is explained in the report of the British Association, 1859. The report says, "he succeeded in transmitting signals across the Tay and other sheets of water by the aid of the water alone as a means of joining the stations. His method is to immerse two large plates connected by wires at each side of the sheet of water, and as nearly opposite to each other as possible. The wire on the side from which the message is to be sent is to include the galvanic battery and the commutator or other apparatus for giving the signal. The wire connecting the two plates at the receiving station is to include an induction coil or other apparatus for increasing the intensity and the recording apparatus. The distance between these plates he distinguished by the term 'lateral distance.' He found that there was always some fractional part of the power from the battery sent across the water. There were four elements on which he found the strength of the transmitted current to depend: first, the battery power; second, the extent of surface of the immersed metal struts; third, the 'lateral distance' of the immersed struts; and fourth, in an inverse proportion the transverse distance, or distance through the water. As far as his experiments led him to a conclusion, doubling any one of the former three doubled the distance of transmission. If then, doubling all would increase the intensity of the transmitted current eight-fold, he entered into calculations to show that two stations in Britain, one in Cornwall the other in Scotland, and corresponding stations well chosen in America, would enable us to transmit messages across the Atlantic." Lately the *Pall Mall Gazette* has been publishing the views of persons interested in Marconi's system of wireless telegraphy, in which they express their belief that communication with the United States by means of the system is practicable. It adds, "There is no intention of competing with land lines." The *Electrical Review*, New York, says, "There is no doubt that the company will not compete with sea-lines either." It makes a calculation, and says, "the distance from London to New York is about 74 degrees 50 minutes of the arc of the earth's great circle. Taking the radius of the earth to be 4,000 miles, the towers at the two ends of the line would have to be 1,038 miles high—and even then the messages would graze the surface of the Atlantic."

The submarine cable has had a rapid career since the first was laid across the English Channel in 1851. The only seas under which the cable does not lie, are those of the middle Pacific, and these also will soon be traversed. There are at present 1,460 cables laid, 1,142 of which are owned by nations, and 318 by companies. The total mileage is 166,299 nautical miles, enough to reach eight times around the earth on a great circle.

One of the principal features of the electrical exhibition of New York will be Government exhibits, in which will be found apparatus belonging to the Army and Navy service corps and the Weather Bureau; a searchlight from the Spanish cruiser *Vizcaya*, taken from the vessel after the naval fight at Santiago, together with a searchlight taken from the *Maine*. The "Navy Standard" of wiring will be in evidence, showing special cut-outs, branches, and switches.

The Nernst Lamp has been very much in evidence lately, and it is said the incandescing rod in a 400-volt lamp should be 1⅜ in. long. The cost of lamps is said to be 5 dollars to replace ordinary arc lamps. The watts required is 1·5 to 1·6 per candle, which lies between those of arc lights and incandescent lamps. The colour of the light is whiter than glow lamps', and approaches that of the arc lamp. The life of the rods is 500 hours, and their renewal is not very costly. The temperature of the arc is 3,000 deg. Centigrade. Lamps as small as 20-candle power can be made for 400-volt circuits.

Quite a number of wonders have come upon us in the electrical line lately, and one of the most wonderful, perhaps, is the picture by telegraphy. The *Electrical Review*, New York, reproduces one of these pictures, which is a portrait (one-half original size) received at New York from St. Louis over 1,550 miles of line and one repeater—reproduced without retouching. Pictures made in this way depend on the synchronism of apparatus at the two ends of the line, and the difficulty of obtaining this has delayed the successful manipulation of the business for so long. Biene and Cassini used pendulums at the ends of the line. The machines used have been fitted up in newspaper offices in the cities of St. Louis, Chicago, Philadelphia, New York, and Boston, and the photograph shown was made in the *New York Herald* office. Mr. E. A. Hummel is the inventor. Two cylinders of equal size are fitted in the machine at each end. The drawing at the sending end is made on a piece of stout tinfoil in an insulating ink. This is wrapped about its cylinder, and turned under a platinum point, which makes contact with the tinfoil except where it crosses one of the lines of the ink drawing. At this point the circuit is interrupted momentarily. At the receiving end a similar cylinder, turning synchronously, has upon its surface a sheet of paper covered with carbon impression paper, outside of which is a sheet of thin semi-transparent paper, and the break-circuit signals operate a stylus which is pressed upon this surface, so producing the lines of the drawing. The cylinder is driven at a steady speed of 14 revolutions per minute by clockwork similar to an astronomical driving-clock, and controlled by a Faraday wind-vane governor. The platinum point bears lightly upon the surface, and is carried upon a carriage similar to that of a lathe. At each revolution of the sending cylinder, a pivot upon it engages in a ratchet upon the head of the carriage screw, and moves the platinum point forward by an amount dependent upon the pitch of the ratchet. There are four ratchets, which can be set in the carriage screws of both receiving and sending instruments, and both the size of the cylinder to be used and the coarseness of the ratchet to be put in gear are agreed upon by ordinary telegraphic correspondence. The clockwork at each end is driven by a weight and an endless steel belt. A winding drum, moved by an electric motor, winds up at each revolution enough of the slack to keep the apparatus constantly moving. When either the sending or receiving carriage has reached the end of its travel, an automatic stop throws the instrument out of circuit. Three sizes of cylinders are in use, and four speeds of travel. The picture shown was received in about 26 minutes. It is possible to send a picture from one station and have it received simultaneously in the other four.

The Island of Bornholm, in the Baltic Sea, is said to consist of magnetic iron ore, and sailors have long dreaded its influence on their compass needles. The effect is felt for distances of miles, and on sighting the islands the mariners begin to steer by the aid of the lighthouses. It is said that a magnetic needle in a boat close by the island takes a vertical position.

At a recent meeting of the Institute of Marine Engineers to discuss the paper read by Mr. Nicholls an expression as to the want of data on electric motors for deck machinery was given. The following table, which is given by Mr. Alton D. Adams, on the efficiency of small motors may be of interest.

Watts delivered.	H.P. delivered by motor.	Watts lost in armature.	Watts lost in coils.	Watts lost in currents.	Efficiency.
548	½	40	44	91	68 per cent.
995	1	65	60	134	75 ,,
1,913	2	110	99	212	78 ,,
2,798	3	130	110	320	80 ,,
4,548	5	170	176	473	82 ,,
6,661	7½	220	220	626	84 ,,
8,674	10	260	264	690	86 ,,

A steam engine of 5 H.P. does not give anything like an efficiency of 82 per cent.

OIL MOTOR BOATS.

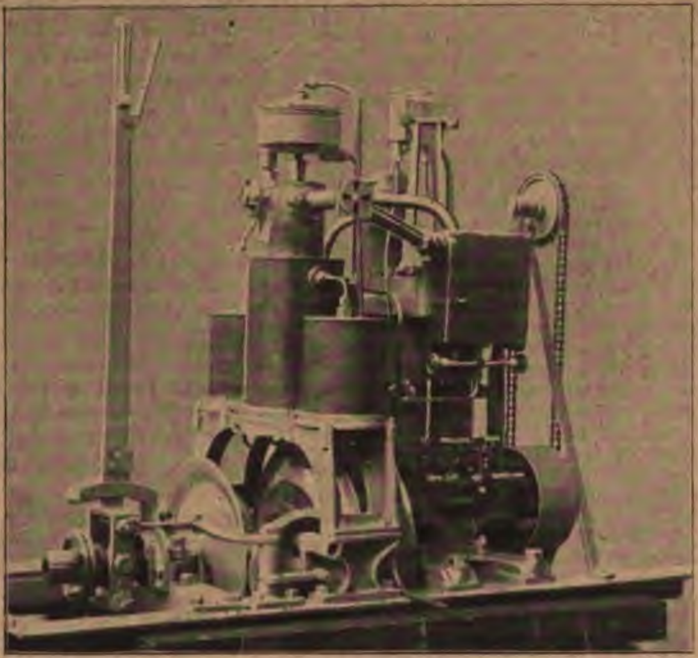
FOR small launches where the people in them have to sit in the open, and where, if coal were used, they would be smeared by coal-dust and smoke, a spirit or oil motor appears to be the proper arrangement. Less space is required for the fuel, and the boat itself can be kept tidy and clean. Two such boats are to form part of the equipment of a steamship of the American Line, when she leaves on a cruise to the West Indies. The dimensions of the boats are:—Length, 30 ft.; beam, 8 ft.; keel, white oak sided, 3 in.; moulded at fore end, 4 in.; at stern, 6 in. stem of white oak; stern post and over-hang of quartered white oak; span, 11 in.; centres, steam bent sided, 1¼ in. The boats will have open seats and lockers provided in the motor-room. A 12 H.P. alco-vapour will be fitted, and the tank capacity will be two barrels. There is to be a double tow just aft with crosshead for towing the ordinary boats for landing parties. There is also to be a steering wheel and chain gear.

Another type of motor for a launch was on view at the Aquarium, and is manufactured by the Motor Carriage Supply Co. It is attached to the shaft in the usual way, but there are ahead and astern gearing fitted between the motor and the propeller shaft. This reversing gearing consists of conical pulleys. Ahead cone (2) is pushed against ahead cone (1) by the lever going forward. The engine runs free by the lever being placed in the middle position; and, when the motion is to be reversed, the lever is drawn back, the cones are separated, and the bevel gearing in the jack-in-the-box comes into play and reverses the direction of the propeller. Deep ribs are attached to the cylinder to assist in carrying away the heat, and there is a cowl on the top which blows down air in the cylinder to assist in cooling the cylinder, and this, of course, is increased as the speed of the boat increases.

The advantage of an oil motor to the owner of a launch is that a boiler is not required, and there is no smoke from the chimney. In fact, a chimney is placed on such a boat to make it like its neighbours driven by steam. But the chimney is a superfluity, as there is no smoke to carry away. Then the heat of the boiler and the dirt produced by the use and handling of coal is done away with.

The difficulty with such engines was the reversing of the motion, for it is a *sine qua non* that a marine engine must be capable of being reversed. In the case of the Parsons rotary system an extra engine had to be fitted in the turbinia to reverse the motion of the boat. In the case of the Daimler launch engine a very simple principle of mechanism has been applied for producing the reversing motion. That mechanism is a system of bevel wheels constructed of cast-iron.

There is a bevel wheel fixed to the main shaft of the engine, which is turned with a conical bevel on the outside and also a conical bevel on the inside of the rim, which acts as a friction clutch. This wheel is covered with leather. The side bevel wheels are covered with rubber. A lever which runs in the direction of the shaft moves the bevel wheels in and out of gear. When the lever is moved towards the engine it puts the shaft in gear, and also by means of links it pulls the two side bevel wheels out of gear. When the lever is pulled back, it pulls the inner bevel wheel out of gear, and puts the side indiarubber-clad bevel wheels into gear.



Daimber Oil Motor.

The fuel used is benzine of ·680 to ·700 specific gravity, which costs 11d. per gallon in London. The cost of running is about 1¼d. per actual H.P. per hour. A 4-H.P. engine costs about 6d. per hour in oil to run it.

But the oldest form of this type of marine motor is the Priestman engine. This is made in two types: the single-acting, which is made in sizes of 4 I.H.P. to 22 I.H.P.; and the double-acting, made in sizes up to 90 I.H.P. In the former an impulse is obtained for each revolution, and in the latter type two impulses per revolution—in each case the Otto cycle is used.

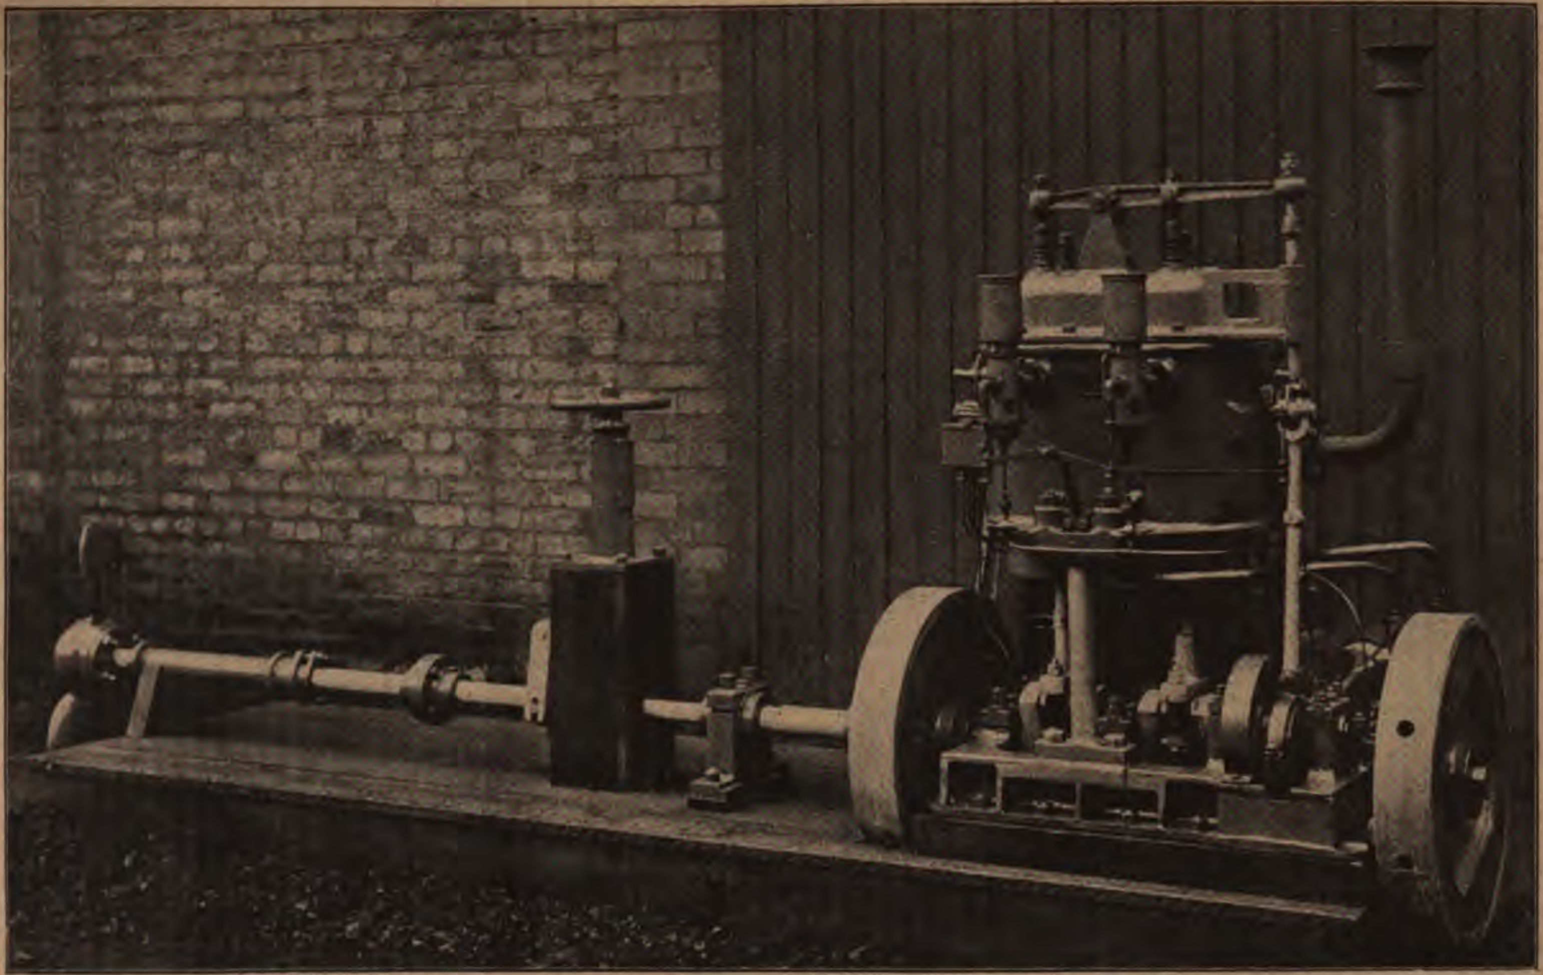
The mode of working is as follows:—Ordinary lamp oil, contained in a tank forming the engine bed, is *sprayed,* mixed with atmospheric air, vaporised and exploded in the cylinders by means of an electric spark or alternatively with a hot tube.

The engine is effectively governed on the "graded charge" principle by an apparatus which automatically regulates the supply of oil and air to the cylinders. Lubrication is effected by the condensing of the oil vapour on the walls of the cylinders.

A very simple and efficient form of self-starter is adopted, which renders the setting of a large engine in motion an easy matter. This consists of a hand air-compressing pump, by means of which a charge of air can be compressed and passed into one of the two motor cylinders, carrying with it an oil spray vapour, and giving sufficient pressure in the combustion chamber to give the engine a kick-off. In starting the engine has to be heated up for about fifteen minutes, and subsequently the heat in the vaporising chamber is automatically maintained by means of the exhaust gases.

As the rotation of the engines is always in the same direction, and the engines are kept going at the same speed, alteration in the speed and direction of motion of the boat is effected by means of the McGlasson patent reversing propeller, the blades of which are feathered, and thus any speed can be almost instantly obtained, from "full speed ahead" to "full speed astern." This regulation of speed can easily be controlled by the steersman; and, as the engine requires practically no attention whilst running, the whole boat can be managed by one man exclusive of the man at the wheel.

They have been supplied for barges, fishing-boats, and as auxiliary power in sailing vessels with great success. One pair was fitted in a 30-ton yacht belonging to Mr. Fred. Maden, of 34, Norwood



PRIESTMAN'S MARINE OIL MOTOR.

Avenue, Southport. During two seasons they cruised through Wales, the Isle of Man, Ireland, and the North of Scotland, and ran between 4,000 and 5,000 miles. The owner of the yacht says there is no priming in rough weather, no racing of the engine when the propeller is out of the water, and a great saving of space usually taken by a steam engine and boiler. Another, of 5 H.P., was fitted in a launch belonging to Mr. E. O. Dykes, Hessle, East Yorks. It has run for two seasons, and during the last two was worked by his gardener. The economy of space for engine and fuel was a great advantage, and after running the whole of two days had sufficient oil left from one supply to run a third.

The cost of working of this oil marine motor is a distinct advantage, for it does not require expensive oils, but the ordinary petroleum lamp oils. Careful trials by Professor Unwin showed that the cost per I.H.P. for oil was ·43d., and ·5d. per effective brake H.P.

The Magnolia Anti-friction Metal Company and Others v. Sugden and Others.—Mr. Justice Mathew, in delivering his considered judgment on Thursday, May 11th, said that he had received a letter from Mr. Sugden, stating that he had sent to the plaintiffs' solicitors the assignments, after executing them, and that he was prepared to submit to his Lordship any question that might arise between him and the plaintiffs in relation to their form. His Lordship hoped that no such question would arise, but if so, there would be liberty to apply. His Lordship went on to say that he had to determine what the damages ought to be, as the result of this long litigation. The question was what damage had been sustained by a breach of the contract of 1891. If that contract had been fulfilled, what would the position of the plaintiffs have been? The defendants had been selling an inferior metal for £30 or £40 a ton, not half as good as the metal of the plaintiffs. In point of fact what the defendants were attempting to do was to compete with the plaintiffs by the manufacture of inferior metal. What they did was, first, to put forward a quantity of counterfeit metal, but in respect of that very discreditable conduct, an action had already been brought against them. Further, they sold 325 tons of inferior metal, and his Lordship had to consider what the position of the plaintiffs would have been if the partnership, instead of breaking their contract, had properly surrendered and given back the business to the plaintiffs. What would the plaintiffs have sold of their superior metal? He was not satisfied that he ought to go beyond about 200 tons per annum, and in three years that would amount to about 600 tons. The quantity actually sold by the plaintiffs was 463 tons, and the difference, therefore, was about 140 tons. Some £35 a ton would be the profit which would have been received by the plaintiffs if the contract had not been broken, and if the business had been handed back as it ought to have been. Some addition must be made for the expenses to which the plaintiffs had been put in order to recapture their business. His Lordship arrived at the conclusion that his judgment ought to be against the defendants for the sum of £5,500 and costs.

NAVAL ENGINEER APPOINTMENTS.

THE following appointments have been made at the Admiralty from April 25th to May 24th, 1899 :—

Aborn, G., fleet engineer to the *Pembroke*, for the *Sutlej*, to date May 13th.

Burnett, W. C., chief engineer, has been advanced to the rank of staff engineer.

Butcher, J. B., engineer to the *Vivid*, for the *Decoy*, undated.

Coad, H. J., chief engineer to the *Duke of Wellington*, for special service, to date May 1st.

Cudlip, E. W., chief engineer to the *Vivid*, as overseer at London and Glasgow Shipbuilding and Engineering Company, to date May 13th.

Dalrymple, J. H., chief engineer to the *Blonde*, to date May 16th.

Darley, A. C., engineer to the *Vernon*, for the *Jaseur*, to date May 13th.

Davis, H., assistant engineer to the *Benbow*, to date May 19th.

Dawson, T. J. (acting) engineer to the *Resolution*, undated.

Duffell, W. J., engineer to the *Pembroke*, for the *Janus*, to date May 19th.

Edgar, E. J., chief engineer, has been advanced to the rank of staff engineer.

Edwards, E., engineer to the *Pembroke*, for the *Desperate*, to date April 18th.

Fleetwood, J. L., acting chief engineer to the *Antelope*, to date May 4th.

Glen, W., assistant engineer R.N.R., has been promoted to the rank of engineer.

Gordon, F. A., assistant engineer to the *Pembroke*, for the *Astræa*, on recommissioning, to date May 19th.

Green, D. P., engineer to the *Royal Sovereign*, for the *Banshee*, undated.

Guyer, T. S., engineer to the *Centurion*, for service at Wei-hai-wei, to date May 5th.

Hall, A. C., assistant engineer to the *Pembroke*, for the *Astræa*, on recommissioning, to date May 19th.

Hardcastle, C. V., engineer to the *Vivid*, as instructor in working machinery of torpedo-boats, to date May 19th.

Hart, Alfred, chief engineer to the *Astræa*, to date June 15th.

Hean, H. G., engineer R.N.R., to the *Duke of Wellington*, for course of instruction, to date June 6th.

Hume, A. G., to be assistant engineer R.N.R.

Jose, F. W. R., engineer to the *Vivid*, for the *Sunfish*, to date May 19th.

Juniper, W., chief engineer, has been advanced to the rank of staff engineer.

Kingsnorth, A. F., engineer, has been promoted to the rank of chief engineer in her Majesty's fleet.

Kingsnorth, A. F., chief engineer to the *Harrier*, to date April 1st.

Kingswood, R. W., engineer R.N.R., to the *Duke of Wellington*, for course of instruction, to date June 6th.

Main, R., engineer to the *Duke of Wellington*, for the *Kestrel*, to date May 5th.

Mandling, W. J., fleet engineer to the *Duke of Wellington*, for the *Cordelia*, to date May 5th.

Morley, H. S., assistant engineer to the *Colossus*, to date May 19th.

Moysey, A. H., engineer to the *Pembroke*, for the *Swordfish*, to date April 11th.

Murdoch, H. C., to be assistant engineer R.N.R.

Pedrick, J. R. J., staff engineer, has been advanced to the rank of fleet engineer.

Plant, S. L., to be assistant engineer R.N.R.

Ramsay, Walter, engineer R.N.R., to the *Duke of Wellington*, for course of instruction, to date June 6th.

Rawsthorne, G., to be assistant engineer R.N.R.

Reid, W., to be engineer R.N.R.

Rule, R. T., engineer to the *Duke of Wellington*, for course of instruction, to date June 6th.

Russell, C. S., engineer to the *Pembroke*, for the *Porcupine*, to date April 11th.

Sadler, F., engineer to the *Duke of Wellington*, for course of instruction, to date June 6th.

Silk, E. S., engineer to the *Fembroke*, additional, to date May 19th, and to the *Endymion*, to date June 8th.

Stainton, G. H., engineer to the *Pembroke*, for the *Sturgeon*, to date May 19th.

Starkey, A. E., assistant engineer, to be engineer R.N.R.

Stevens, Charles, engineer to the *Renown*, to date May 19th.

Stevens, W. C., engineer to the *Pembroke*, for the *Bittern*, to date April 18th.

Stuart, J. J., fleet engineer to the *Endymion*, to date June 8th.

Vine, E. R., fleet engineer, has been placed on the Retired List, with permission to assume the rank of inspector of machinery.

Wallace, J., engineer R.N.R., to the *Duke of Wellington*, for course of instruction, to date June 6th.

Williams, R. J., engineer R.N.R., to the *Duke of Wellington*, for course of instruction, to date June 6th.

INDUSTRIAL AND TRADE NOTES.

THE CLYDE AND SCOTLAND.

(From our own Correspondent.)

THE Fairfield Shipbuilding & Engineering Co., Govan, launched on the 12th ult. the *Kinfauns Castle*, a splendid mail steamer for the Castle Mail Packet Co.'s service to the Cape. The event attracted a very large concourse of spectators both inside and outside the yard, and the launching of the vessel was very successfully accomplished, the naming ceremony being performed by Lady Georgina Home-Drummond. The *Kinfauns Castle* is noteworthy as being the first twin-screw steamer built for the Castle Line, and is intended to be the fastest in Sir Donald Currie's Cape service. In the matter of dimensions she is one of the largest of Fairfield's productions, coming next in this respect to the famous Cunarders *Campania* and *Lucania*. She is 532 ft. in length, 59 ft. 3 in. beam, and 38 ft. 9 in. depth, moulded. Her gross tonnage is about 9,700 tons, and her engines are of 10,000 I.H.P. She will have accommodation for 800 passengers. A sister-ship, the *Kildonan Castle*, will be launched from Fairfield early in August.

The Fairfield Co. and the London & Glasgow Shipbuilding Co., Govan, have each received an order from the British Admiralty for a first-class armoured cruiser of 9,800 tons displacement, and with engine power sufficient to give the vessel a speed of 23 knots. With these two important orders the amount of naval work on hand in Clyde yards at present reaches to considerably over 100,000 tons.

Messrs. A. & J. Inglis, of Pointhouse Shipyard, have just launched a paddle steamer for passenger service on the Clyde, which in the matter of speed will, in all likelihood, exceed anything of her size afloat in the Clyde. This is the *Waverley*, for the North British Steam Packet Co., and the speed guaranteed is 18 knots. The *Waverley* is to be fitted with compound engines and the conventional "haystack" boiler.

The second of the Fairfield Co.'s smaller cruisers, H.M.S. *Highflyer*, went down the Clyde on the 15th of May, and on the following day got through her builders' trials in the Firth. In the afternoon she left for Devonport, from which dockyard her trials will be conducted shortly. Her sister-ship, the *Hermes*, will shortly begin her official trials in the Channel. The torpedo-boat-destroyer *Leven* got through her speed trials very successfully, and her survey has ended as satisfactorily. She will be clear for delivery in a few days.

Messrs. Wm Simons & Co., Limited, Renfrew, launched on 12th ult. a powerful steam-dredger, named *Pervi*, which is the first of two similar vessels being built by the firm for extensive dredging operations in connection with the improvement of Port Arthur and Talienwan. The vessel is capable of dredging and discharging 1,000 tons of soil per hour, and of working to a depth of 40 ft. below the water level. In addition to being provided with a chain of buckets for discharging into barges alongside, the vessel is fitted with a sand suction pump, also a mud discharging pump, to which is attached fully 2,000 ft. of shore discharging pipes, carried on floating pontoons, having flexible joints. Two pairs of compound surface-condensing engines are fitted for propelling the vessel at a speed of seven knots per hour. Electric light installation is provided for working day and night.

Messrs. Robert Duncan & Co., shipbuilders, Port-Glasgow, have received an order for a four-masted schooner, which will be constructed on somewhat similar lines to the *Honolulu* built in 1896 by the same firm for Mr. John Ena, of Honolulu. The new vessel will be of larger tonnage than the *Honolulu*, which was 1,073 tons, and—unlike that vessel, which had all her four masts of the same height and carrying fore-and-aft sails only—she will be square-rigged on the fore mast.

With reference to the order which, as stated in last month's note, Messrs. D. J. Dunlop & Co., Port-Glasgow, have secured from the Woermann Line, of Hamburg, for the construction of two passenger steamers of 6,000 tons each, it is reported that the contract would have been placed with German builders, but "the prices asked by the German firms invited to tender were higher than the Scottish firm's tender, besides which a much longer time was required to complete the boats."

The well-known firm of Messrs. Scott & Co., Greenock, has been formed into a joint-stock company, under the title of "Scott's Shipbuilding and Engineering Co., Limited," with a capital of £300,000 divided into 30,000 shares of £10 each. The businesses to be carried on are, as formerly, that of Scott & Co., shipbuilders and engineers, and the Greenock Foundry Co., engineers and ironfounders, East Stewart Street, Greenock. The signatories are: John Scott, R. Sinclair Scott, and Charles C. Scott, shipbuilders and engineers, Greenock; Jas. Henry Scott, merchant, London; Mrs. Annie Scott, Hawkhill, Largs; Colin W. Scott, merchant, 94, Hope Street, Glasgow.

From the boiler works of the Greenock Foundry Co., there lately emanated two unusually heavy marine boilers, which have been safely placed on board ship by the powerful crane at Victoria Harbour, Greenock. These boilers were of 90 tons each and were put on board the steamer *Calchas*, recently launched by Messrs. Scott & Co., for the Ocean Steamship Co., of Liverpool.

That the development of already established, and the opening up of fresh, fields of commercial enterprise, in various parts of the globe, are matters more and more on the increase is indicated by the demands being made on builders of light-draught craft for shipment abroad. On the Clyde several firms who almost wholly confine themselves to work of this class are exceptionally busy at present; and, as their vessels, after construction, are taken to pieces for shipment to their destination, building is proceeding on ground far removed from the usual riverside berths necessary when ships have to be launched into their native element. Messrs. Denny & Brothers, Dumbarton, who have for many years largely engaged in the building of light-draught craft for re-erection and service abroad, are finding it more and more necessary to utilise, for work of this kind, surplus ground belonging to them, lying outside their yard wall, but convenient and handy to one of the yard gates. They are now proceeding to erect, and equip with the necessary plant, a large fitting shed, 150 ft. long by 50 ft. broad, on the ground in question.

Messrs. C. Macdonald & Co., of Mair Street, Plantation, Glasgow, who build steam-launches and the lighter class of vessels, launched, on the 13th ult., the steam yacht *Una*—70 ft. long overall, 11 ft. 6 in. beam, and 7 ft. moulded depth. The noteworthy fact in connection with the launch of the vessel is that, notwithstanding her dimensions, she was built on Messrs. Macdonald's premises—a back yard, so to say—in Mair Street, Plantation, whence she was removed about 6 o'clock a.m., drawn down Govan Road by steam traction-engine, consigned to Prince's Dock, and had her engine and boiler on board before 9 a.m. The machinery has been supplied by Messrs. McKie & Baxter, of Copland Engine Works, Govan.

The work of sounding Glasgow Harbour for the purpose of ascertaining the various depths of water, which is done once in four years, is now in progress. The soundings, when finished, are formed into a chart of that portion of the river and estuary within the jurisdiction of the Trust, and this chart serves as a guide for dredging operations for the next few years. The 1891 soundings were accepted by the Admiralty as official, and still remain on their charts as such, the soundings below Newark Castle being those of the Clyde Lighthouses Trust, and those further down being taken by the Admiralty officials themselves. This year a beginning was made at the Victoria Bridge, and the boat's crew conducting the work have now reached Govan. The soundings in the upper reaches are taken at intervals of 20 ft. across, and 100 yards up and down the river, and in the lower reaches of 20 feet across and 200 yards up and down; more men and boats being employed as the work proceeds Firthwards. The operations require about four months to complete.

A well-known Clyde shipbuilder has invented a type of ship's watertight door and deckhouse window which, in respect of their construction and of the material of which they are made, mark a distinct advance on the kind of door and window frame *at present generally in use*. The feature of the door in question is the insertion, in a groove surrounding the opening, of a specially strong pneumatic tube, half the diameter of which projects from the framework and fits into a groove in the door or window. When the door is shut the tube is fully inflated by automatic action, and the joint is thus rendered absolutely air- and watertight. About 240 such doors and windows are at present being manufactured for the inventor, who will fit them on board a vessel at present under construction in his shipyard. The material of which these articles are being made also constitutes a distinguishing and highly important feature. This is a special metal, for which Mr. Lawson, manager of the new Howe Cycle Works, Glasgow, holds the patent, known as the "Rex" white metal. It is remarkably light, malleable, and requires no annealing after being cast. It is capable of brazing, and is white throughout, and will not corrode under any conditions. In price it compares favourably with gun-metal. As regards weight the 240 doors and windows now being made weigh in the aggregate 14,160 lbs. less than would the same articles made of cast iron, and they will serve the purposes required of such doors and windows much better.

Messrs. Ramage & Ferguson, shipbuilders and engineers, Leith, have contracted to build a screw steam tug to the order of Sir Donald Currie for service at the Cape. Messrs. Hawthorn & Co., of the same port, have received an order to build and engine a steam trawler of about 300 tons for the Royal National Mission to Deep Sea Fishermen. The vessel, which will have triple-expansion engines capable of driving her 12 knots, will be fitted up as a hospital, provision being made for the accommodation of a missionary and a surgeon.

The Leith Dock Commissioners have placed an order with Messrs. W. & T. Averey, Limited, for a set of five automatic grain-weighing machines, by means of which the grain discharging and receiving facilities of the port will be much enhanced. The set of machines just ordered, which are similar in every way to those at present extensively in use at the London docks, will be capable of automatically filling, weighing, and registering 20 bags of grain in one minute.

According to Mr. F. W. Paul, late manager of the Blochairn Works of the Company of Scotland—who has left that company's service to occupy the position of general manager of the Shelton Iron and Steel Co., Limited, Stoke-on-Trent, and who early in the month was entertained to dinner in Glasgow, and presented with substantial tokens of the esteem in which he is held—the competition this country is meeting with from America in connection with the steel trade is not to be underrated. We had heard so much about this matter of late, and had at the same time been enjoying such prosperous trade conditions, that we had almost come to believe that the cry contained but little foundation in fact. It was the fact, however, that during the last 12 months some 10,000 to 12,000 tons of shipbuilding material has actually been landed in the Clyde district and at Belfast from America at prices which home manufacturers would not accept. Moreover, an order had recently been placed in America for 30,000 tons of steel for Australia. To meet this competition, he suggested that the railway companies should recognise the duty that devolved upon them to take their part in the international struggle for commercial supremacy, and by carrying goods at lower rates assist the industries of this country in maintaining, if not enhancing, their present condition. Pig-iron manufacturers also should seriously consider what could be done to lessen the cost of the raw material to the steel manufacturer.

During the past four years the representative of the Glasgow Chamber of Commerce and Merchants' House on the committee of Lloyd's Registry has been Mr. Ross, of Messrs. Ker, Bolton & Co. Mr. Ross, having intimated his desire to retire, Mr. Henry Bell, of Messrs. Bell, Brothers & McLelland, has been appointed representative in his stead. At the meeting of the Chamber of Commerce, at which the appointment was made, the president intimated that a communication had been received from the Clyde Steamship Owners' Association stating that at a meeting of directors the whole position of the representation of the Clyde district on Lloyd's was discussed, and there was a unanimous feeling that the present representation was inadequate. It was felt that the importance of the district as a shipowning, shipbuilding, and an underwriting centre entitled it to at least equal representation with Liverpool, and that the time had come to approach Lloyd's Committee on the subject with the view to a local branch being formed. They asked the Chamber to appoint representatives to a meeting to be held, when the matter would be considered. Mr. W. F. G. Anderson pointed out that this had long been a standing grievance in the Clyde district, and it was largely on account of this that the British Corporation had been formed. That corporation had been an entire success, and had given satisfaction to every one connected with it. Mr. J. A. Duncan urged the importance of more representation on Lloyd's Committee. Representatives were appointed to attend the meeting convened by the Steamship Owners' Association.

THE TYNE.

(*From our own Correspondent.*)

Shipbuilding.—So far as concerns the ordering of new tonnage, business in this district continues in quite a stagnant condition, and if this continues, the yards—though still quite full of work— must in the course of a few months begin to show symptoms of slackness. The fact that the quantity of floating tonnage in existence is somewhat in excess of the demand is shown by the continued depression in freights; and the addition, to an already overstocked market, of the vast amount of tonnage now approaching completion in our yards will not tend to render less discouraging the prospect for the shipowner. During April and the greater part of May the weather has been exceedingly unfavourable for outdoor work, and much time was lost by the platers, riveters, and other outdoor workers in consequence. This would, perhaps, not have been so severely felt, if the men had not already lost a good deal of time when there was nothing to prevent them from working; but the two circumstances, of wilful abstention from work in the first place, and compulsory abstention in the second, have so far altered the outlook that it is now universally felt that last year's output cannot be equalled, or even approached, in the current year. The officials of the Boilermakers and Ironship Builders' Society, however, take a hopeful view of the future, as may be seen by the report (May, 1899) from the chairman, secretary, and "delegate" of the Tyne District Committee, which says, "There is, as yet, no falling off in briskness, for as soon as launches take place the berths have been immediately cleared for the laying-down of other keels, and the whole of the available space for shipbuilding in the various yards on the river continues to be fully occupied. At a number of our shipyards spare ground is being taken in, and extensions on a large scale are being pushed ahead with the view of providing room for the building of much larger vessels than have hitherto been constructed on the Tyne. New and heavy machinery is also being put down, and, when the arrangements are fully completed, the local employers will be in a position to compete for the building of all classes of vessels without any restrictions as to size, speed, or equipment."

Messrs. Armstrong, Whitworth & Co. have made an application to the Tyne Commissioners, having reference to the driving of piles in the river foreshore, for the purpose of lengthening the building berths, and it has been decided that a deputation from the latter body shall visit the yard on an early date to examine and report upon the matter. It is quite certain that what Messrs. Armstrong, Whitworth & Co. are asking for is bound to benefit the district, being merely a question of development, and it may be taken for granted that the Commissioners will place no unnecessary obstacles in the way of local enterprise.

Messrs. Wigham, Richardson & Co. have a large boat in course of construction for a German company of high standing, and have several other contracts of an exceptionally important kind to go on with. There are vessels in the water undergoing repairs or final equipment for sea, and in all the departments a condition of high-pressure activity is maintained. Messrs. Wood, Skinner & Co., have their berths fully occupied with cargo boats, and at Messrs. Dobson's yard a similar state of things exists.

It is understood that the site—several acres in extent—which was formerly occupied by the Walker Ironworks, and which is situated a little to the westward of Messrs. Armstrong, Whitworth & Co.'s Low Walker yard, has passed into new hands, and will soon be utilised in connection with the initiation of an important industrial enterprise. The exact nature of the undertaking has not yet transpired, but it is believed in the neighbourhood that it is something in some way associated with the fitting out of ships. Two blast furnaces are still standing in the place, but they are of a somewhat antiquated type, and would scarcely be of much use under modern conditions of production. The rolling mills were dismantled, however, long ago, and under these circumstances the presumption may be hazarded that the manufacture of steel or iron forms no part of the project in the minds of the new proprietors. Whatever the exact nature of the enterprise may be, however, there is no doubt that it will have exceptional chances of success, as the situation of the site is about the best in the district, affording quick access to both rail and river, and being in close proximity to some of the largest shipbuilding and engineering works in the north.

Messrs. Hawthorn, Leslie & Co. are actively engaged in preparing for the laying down of the three torpedo-destroyers ordered by the Admiralty, and they are also very busy with mercantile work. It is strongly hoped that the volunteer boat, which is now supposed to be in the market, will be placed with this firm, who have built so many splendid vessels for the well-known Russian syndicate.

One of the vessels now on the stocks at Messrs. C. S. Swan & Hunter's yard is said to be the largest at present building in the British Isles, being considerably over 600 ft. long, and of proportionate dimensions in other respects. This vessel is understood to be for the Cunard Co., and is to be fitted out in a unique style. During the exceptionally wet weather that has lately prevailed, the utility of the covered berths at this establishment was abundantly demonstrated, work having been but little interrupted on the vessels building in these sheltered positions, while in connection with the constructive operations on vessels not so protected a good deal of time was unavoidably lost. Should the firm decide on covering in the whole of the berths in their yards, it may come to pass that—in this case at all events—shipbuilding and pontoon building, may be carried on with as little interruption as engine building. It is not yet known whether the firm have any such intention; but, in view of the great results that have followed their previous bold advances in development, it is by no means out of the range of probability that they will carry to its legitimate conclusion the important principle they have as yet but partially applied.

The Palmer Shipbuilding & Iron Co. have put off the stocks several exceptionally large vessels this year, and have one or two others almost ready for launching. Some disappointment has been felt in the district through the company's tender for one of the cruisers recently ordered by the Admiralty not having been successful; and even the acquisition by the company of three torpedo-destroyers has not dispelled, or even greatly lessened, the popular dissatisfaction. The fact is that the Jarrow people are (with good reason) proud of their yard, and naturally think that, when the larger class of the country's battleships are given out to private builders, one at least of them ought to find its way to the well tried and amply equipped establishment which is to Jarrow what the great Elswick establishment is to Newcastle.

The Tyne Shipbuilding Co. have their three berths occupied, the vessels on the stocks being in the various stages of framing, plating, and preparing for launching. In the initiatory departments work is exceedingly busy, and it is believed that there are orders enough on the books to keep the place busy for at least another twelvemonth.

Messrs. Readhead's yard continues to maintain an appearance of great briskness, the four vessels on the stocks being of large size, while others of equal dimensions are in preparation. At the small yards between Tyne Dock and the river entrance, the berths are well filled with fishing vessels, and the graving docks within the same area are fully occupied with vessels, undergoing painting or repairs. A rumour is current, which appears to be well founded, that a site has been secured at North Shields, on which a newly formed company are about to erect premises to be adapted to the building of ships and engines of a small class. Repair-work will probably also be undertaken, and it is stated that a machinery equipment, of a very complete and elaborate kind, will be provided. There seems to be abundant scope for an establishment of this kind, as the demand for fishing vessels and other small craft has been well sustained for some years past, and is at present so good as to severely tax the existing sources of supply.

Engineering.—There is not, at the moment, any sign of the demand for an advance of wages put forward some time ago by the engineers being persisted in, and it is therefore probable that the steady work now going on in the factories will meet with no interruption during the next few months. The abandonment of this wages claim, simply because the employers declined to grant it, is an incident of the greatest significance, and is quite a new departure for the engineers, or any other great body of trade-unionists, to make. For many years it has been part of the gospel of trade-unionism never to recede from a position once deliberately taken up without first trying the chances of battle. In other words, they were not particularly given to the uncongenial task of "eating the leek." The upshot of the struggle over the hours question in 1897 has, however, taught the engineers to shape their policy differently, and to place their standard of "honour" on a somewhat lower height. They have apparently been impressed with the lesson that it is folly to persevere in a course which is sure to end in disaster, and they could hardly fail to see that any attempt to enforce the demand referred to must have inevitably ended that way. It is to be hoped that under similar circumstances, should such arise in the future, other bodies will be guided by similar considerations, and not allow themselves to be dragged into ruinous disputes by the mistaken notion that it is dishonourable to "retract." The wisest of men may sometimes make mistakes, and it is no dishonour to admit a mistake or to abandon a position which is found to be untenable.

At the Wallsend Slipway Works there are a number of important repair contracts being carried out, and the new work in hand is considerably above the average. The St. Peter's Engine Works continue to be busy in all departments, and the works of Messrs. T. Toward & Co., in the same locality, have as many orders in côurse of execution as are sufficient to keep the machinery fully going, and a full staff of hands employed. At the works of Messrs. R. Stephenson & Co., South Street, Newcastle, both the marine and locomotive departments are busy, the latter particularly so, and in the oil-engine department a considerable pressure of work exists.

The Elswick Ordnance Works still show a high state of activity throughout, and it is just announced that a large order for guns for the Royal Navy has been received from the Admiralty.

The new forge which is being erected by Messrs. H. Fownes & Co., on a convenient site in the vicinity of Tyne Dock, is rapidly approaching completion, and the machinery equipment —which is to be of the most effective description—is also being actively carried out. Productive work will be commenced at a very early date, and we understand that the firm have already booked a large number of orders. The engine and ship repairing works of Messrs. C. R Toomer & Co., Limited, Tyne Dock, are, and have been for some time past, very busy, the special facilities which the firm possess for the prompt execution of contracts being much appreciated by shipowners.

At the works of Messrs. Newton & Nicholson. in which the manufacture of Taylor's patent corrugated metallic packing for joints is the speciality, business is exceedingly brisk, and is likely to continue so for a long time to come. The strain upon the firm's resources, to keep pace with the demand for this packing, has been so great that extensions had become imperatively necessary, and since the opening of the works some few years ago they have been more than quadruple in extent.

THE WEAR.

(From our own Correspondent.)

Shipbuilding.—Among recent announcements of interest to shipping communities is one to the effect that Messrs. Short Brothers, of the well-known shipbuilding works at Pallion, have secured at Seaham Harbour sites for a new shipyard and engine works, and a graving dock capable of accommodating the largest vessels that are likely to enter the port under the improved *regime* that is about to be established. In connection with this firm's yard at Pallion, there is a rumour afloat that the officials of the Boilermakers' Society are trying to get it under their control. We do not disguise the hope that this may turn out untrue, for the yard under present arrangements is a standing illustration of the fact that shipbuilding can be carried on independently of the Boilermakers' Society, and that a business conducted on such conditions may even attain exceptional success.

The tonnage launched in April, 1899, shows a distinct falling-off when compared with April, 1898, the amount for the former period being 11,000 tons, and for the latter 28,000 tons. Luckily this does not indicate a corresponding falling-off in the volume of trade, and the disparity is doubtless due to the circumstance that this year an unusual prevalence of wet weather interfered with the finishing of vessels, and consequently kept them on the stocks longer than was expected.

The electrical machinery at Sir James Laing's new yard is now in full operation, and is found to be a marked improvement on the steam-driven plant. The firm have six large vessels on the stocks, and an oil-ship undergoing an extensive overhaul in the Cornhill Dock. Messrs. R. Thompson & Sons have also a large repair contract in hand, in addition to the new work, which is considerable. The state of business at the North Sands Yard (Messrs. J. L. Thompson & Sons') is still all that could be desired, the berths being fully occupied, and there being plenty of movement in the preparatory departments. The special facilities for carrying out repair work, which the firm have provided at their Manor's Quay Works, have been very fully utilised during the whole of the present year, and a good many contracts have been dealt with in the time. A number of new vessels have also been equipped here, and the mooring place beside the wharf is seldom untenanted.

The two yards at the South Dock—Messrs. Bartram's and the Sunderland Shipbuilding Co.'s—are still well provided with work, and at Messrs. Austin's establishment the pressure is quite exceptional. The yard of the Strand Shipbuilding Co. is also very busy, repair contracts forming a very considerable proportion of the work in hand. Builders of ships' boats are fairly well off for orders, and the operatives connected with this branch are fully employed.

Engineering.—Full activity continues to be maintained at all the marine engine works, and in every case vessels are being fitted at the wharves with their machinery. The Palmers' Hill Works are, perhaps, the busiest, the contracts in hand being both numerous and important. The firm are just now re-boilering an old steamer, and have ordered two Deighton's patent corrugated furnaces for the job. Orders for Dickinson's patent crank shaft continue plentiful, and in this, as well as in other departments of the works, special means for accelerating production have had to be adopted.

Messrs. Forster & Sons have opened a new forge at Pallion, in close proximity to the building where, for many years past, they have manufactured a well-known type of stockless anchor. The new forge is intended specially for the forging of stern-frames, rudders, engine shafting, &c., and, as it is being started at a time when the demand for this class of forgings is exceptionally brisk, the prospect of success appears to be good.

The Monkwearmouth Ironworks are kept very busy, the demand for the company's special sections being more than ordinarily good. At the Monk Street Foundry business is as brisk as possible, and most of the other foundries in the district are pressed with work. Brass and copper works are also quite busy, the equipment of new ships absorbing a large part of the product of these establishments.

The new works started by Mr. Richard Lynn at Pallion some little time ago (known as the Westmoor Engine Works) are having a fair measure of prosperity, and the area of production has been enlarged.

The Hartlepools.—The yards of Messrs. W. Gray & Co. are fully supplied with work, most of the vessels on the stocks being of large dimensions. There is also a quantity of repair work in hand, and at the Central Marine Works vessels are being fitted out for sea Messrs. Furness, Withy & Co.'s yard is extremely well employed, and the same may be said respecting Messrs. Irvine's.

Messrs. Richardson's engine works are as busy as could be wished, and quite lately have had a large vessel from the Wear to fit with her machinery. The demand for Morison's evaporator (which is manufactured by the firm) continues to grow, and a further extension of the premises, specially laid out for its manufacture, will probably become necessary. The Hartlepool Steel Works are in full swing, local shipbuilders and boilermakers requiring most of the product, and in the docks business is beginning to show improvement.

Stockton.—At this centre the state of affairs in shipbuilding has shown little change since the advent of 1899, work being plentiful at all the yards, but its progress being impeded by unfavourable weather. Marine engine works are still very actively employed, and other engineering establishments show no lack of orders. Boiler and bridge works are kept briskly going, and at the various steelworks it is found necessary to work all the time possible to keep pace with customers' requirements.

Middlesbro'.—The yard of Sir Raylton Dixon & Co. continues to show the appearance of full activity that has for an exceptionally long period distinguished it, and at Messrs. Craggs & Sons' yard similar evidences of prosperity are presented. Engineering works at this centre show undiminished briskness, and the same may be said of steelworks, boiler works, forges, foundries, &c. In the docks more animation is to be witnessed, the season for timber importation having now practically commenced.

Darlington.—The works of the Darlington Forge Co. are still extremely busy, many of the contracts in hand being of an exceptionally important kind. Other industrial establishments in the locality are doing well.

THE MERSEY.

(*From our own Correspondent.*)

THE exceptional activity which has been reported for some time past throughout all branches of the engineering trades of this district is beginning to show in some directions a tendency to slacken off. This is noticeable chiefly amongst the builders of heavy stationary engines, who here and there are not receiving quite as much new work as old orders run out, whilst in the textile machine making industries there is also a decided quietening down. So far the undoubted lessening activity in the chief shipbuilding centres has not appreciably affected the important machine tool making branch of industry, all the leading firms being still exceedingly busy, many of them having a large amount of marine engineering work in hand, but the effect of any quietude in the shipyards will, of necessity, before long be felt here. There is, however, no probability of any shortness of work amongst machine-tool makers in this district over the remainder of the present year, and in many cases well into next, most firms reporting that they are still getting new orders in, quite equal quantity to those running out—in fact, in many instances, more than they are able to entertain, except for long-deferred delivery. The boiler-making trade in all sections continues extremely busy; locomotive builders are also greatly pressed with work, and the principal firms are not in a position to book orders for some time to come. All branches of electrical engineering are exceedingly well engaged, owing to enormous developments going on in various directions, and hydraulic engineers are in much the same position.

The monthly returns of the leading trade unions show a continued low unemployed list. In the Steam Engine Makers' Society there is only about one per cent of the total membership on donation benefit, whilst throughout the Lancashire district practically a "clear book" is reported. As to the state of trade, some of the marine centres report a slackening off, but this has no appreciable influence on the unemployed list. The United Machine Workers' Association has 2½ per cent. of the total membership on benefit, but locally there are only 1½ per cent. on the books, and at Beswick, Belfast, Hartlepools, Glasgow, Bradford, Doncaster, Huddersfield, Halifax, Blackburn, Ashton, Lancaster, Crewe, Gloucester, Wigan, Edinburgh, Woolwich, Erith, Hammersmith, Hyde, Westwood and Grimsby, there are no out-of-work members. Out of 47 reports as to trade, 27 describe it as "good," and the remainder as "fair."

The annual reports of the Amalgamated Society of Enginers', and the United Machine Workers' Society have during the past month been issued to the members. The Amalgamated Society of Engineers commenced the year 1898 with 91,444 members, and ended it with 83,564—a decrease of 7,880. The income for the year was £450,727, which, added to the balance of £174,852 from the previous year, made a total of £625,579. The expenditure was £417,457, having a balance of £208,121. This showed a saving on the year of £33,269, besides which the amount of the society's indebtedness in December, 1897—£22,900—had been cleared off. The chief item of expenditure was the donation benefit, which cost £120,874; superannuation amounted to £74,688; contingent £52,725; sick benefit £42,573; emergency and local levy grants £33,737; funerals £13,402; benevolent grants £2,784; accident benefit £2,643; and organisers' or local, delegates' salaries and expenses £[illegible],309. In addition to this there were loans repaid, amounting to £45,311. The United Machine Workers' Association started the year with 3,876 members, and closed with 3,440, a loss of 436, no less than 209 of the excluded members having been connected with the Oldham district. The income for the year was £11,811, which, added to a balance of £823, gave a total of £12,635. The society paid £5,813 unemployed benefit; £1,047 sick benefit; £134 superannuation benefit; £214 funeral benefit; a total of £7,209 for four benefits, as compared with £32,156 the previous year. The balance in hand increased from £823 to £1,316, a gain of £493 on the year's working. It may be added that both the Amalgamated Society of Engineers' and the United Machine Workers' Society have definitely joined the new general federation of trades.

There is very little that is really new to report in connection with the Mersey shipyards. The only matter of interest to record is that the torpedo-boat destroyer H.M.S. *Orwell*, built by Messrs. Laird Brothers, completed her official trial on the Clyde on the 2nd May, in the presence of the Admiralty representatives, the results obtained being very satisfactory. The mean speed of the six runs on the measured mile was 30·8 knots, the speed for the three hours' continuous steaming being 30·2 knots. The details of the miles are as follow:—Time 1 min. 57·6 sec., speed 30·6 knots, steam 220; time 1 min. 57·8 sec.; speed 30·55 knots, steam 220; time 1 min. 57·2 sec., speed 30·72 knots, steam 225; time 1 min. 56·4 sec., speed 30·93 knots, steam 225; time 1 min. 57·8 sec., speed 30·56 knots, steam 225; time 1 min. 56·8 sec., speed 30·82 knots, steam 225. After completing the speed trial the vessel successfully carried out her steering trials, ahead and astern, at full speed.

The Atlas Engineering Co., of Levenshulme, Manchester, are introducing several improvements in machine tools. Amongst these is a special wheel-cutting machine for wheels up to 10 ft. and 12 ft. diameter, and 4 in. pitch. One of the chief features of this new design is an arrangement for dividing automatically by means of a notched wheel, which takes the place of division by hand. A latch fits the notch, and is automatically withdrawn, which has the effect of turning a coarse-threaded screw, which screws up the friction wheel actuating the dividing mechanism. The notched wheel, having only one notch, cannot divide inaccurately, as the latch cannot go in before one revolution has been completed. An ingenious arrangement has also been introduced in the driving gear for planing machines, which is adaptable to the angle of belts without the intervention of the ordinary clumsy forged strap forks. This arrangement consists of a square-frame bracket, adjustable about the centre of the driving shaft. This bracket, in addition to supporting the shaft, carries the belt forks, which are actuated by a new trip motion that shifts one belt before the other operates. It may be added that the firm have just completed a considerable extension of their works, a special feature of their large new machine shaft being that all the plant with which it is equipped consists of tools of their own manufacture.

The iron trade here has fully maintained the strong tone reported last month, and there has been a further very considerable advance in prices. Buying has been mostly confined to small quantities for pressing needs, but makers and manufacturers are mostly well sold, and consequently in a position to be indifferent about further business for the present. Local and district makers have little or nothing to offer, and their prices have gone up fully 3s. to 4s. per ton, foundry qualities being quoted about 61s. 6d. to 62s. less 2½ for Lancashire; 58s. 6d. to 59s. 6d. net for Lincolnshire, and about 60s. to 61s. for Derbyshire, delivered Manchester; whilst forged qualities are not quoted under 58s. 6d. to 59s. less 2½ for Lancashire, and 57s. 2d. to 58s. 2d. net cash for Lincolnshire, delivered Warrington. Outside brands are 4s. to 5s. higher, with orders difficult to place for any quantity; good foundry Middlesbrough is now quoted 64s. 4d. net by rail Manchester, with Glengarnock and Eglinton about 67s. 6d. to 68s. net cash, delivered Manchester Docks, and lots of American iron have been sold at 61s. 6d. net.

In the finished iron trade there is less pressure of orders, but the enquiry is quite sufficient for makers in the present state of their order books. Lancashire bar makers have put up their list basis to £7 5s., and North Staffordshire qualities have been officially raised to £7 10s., delivered in this district. Sheets are also higher, £8 5s. to £8 7s. 6d. being now the average. Association list rates for hoops have been advanced 7s. 6d. per ton, and are now £7 12s. 6d. for random, to £7 17s. 6d. for special cut lengths, delivered Manchester district, and 2s. 6d. less for shipment.

In the steel trade prices, which last month showed some irregularity, are again tending to harden. The exceptional activity in various departments for structural work is bringing forward a large demand for material, which seems to be replacing any falling off in requirements for shipbuilding. Ordinary foundry hematites are not now quoted under 72s. to 73s. 6d. less 2½; billets £5 5s. to £5 7s. 6d. net cash; angles £7 5s. to £7 7s. 6d.; bars, £7 15s. to £7 17s. 6d.; common plates, £7 17s. 6d. to £8; and boiler plates, £8 12s. 6d. to £8 15s. delivered in this district.

The metal market maintains a brisk tone, and prices continue on the upward move, list rates for brazed and seamless copper tubes having been put up ½d. and seamless brass tubes ¼d. per lb. delivered Manchester district. List rates are now as under:—Solid-drawn brass boiler tubes, 9d.; solid-drawn brass surface condenser tubes, 10½d.; solid-drawn copper tubes, 11¼d.; brazed copper gas and steam tubes, 11¼d.; brazed brass tubes, 10d.; common rolled brass, 8¾d.; common brass wire, 8½d.; copper wire, 10¼d. per lb.

Little change can be reported in the condition of the timber trade, arrivals having been moderate with deliveries generally fairly satisfactory, stocks mostly light and values steady. Teak squares have arrived in small quantity, and there is a steady demand, with stocks not heavy. Prices have improved, but not to the same extent as for planks. The import of planks has been fairly large, but the demand continues good, at steady rates, and stocks are not excessive. Two cargoes of greenheart have come in, and the stock is heavy.

A leading Liverpool firm of timber and mahogany brokers in their monthly circular make some complaint respecting action recently taken by the Mersey Docks and Harbour Board. "The Board," they state, "have given notice to a number of their tenants at the Canada Dock to quit the premises they hold, thus still further reducing the already limited and totally inadequate accommodation the timber trade possess for conducting their business, and which must entail a very serious disturbance and loss to an important business, which employs upwards of half a million tons of shipping during the year; some 300,000 tons per annum have already been diverted to neighbouring ports, chiefly to Manchester, and the present action of the Mersey Docks and Harbour Board will tend to drive still more of the trade in that direction, and thus make Manchester the chief distributing centre of the timber trade instead of Liverpool."

The coal trade here shows no material change. Pits continue on full time, and the output is moving away with prices firm at late rates. House-fire qualities continue in exceptionally good demand for the time of the year, and there is still none of that accumulation of stocks that usually takes place, whilst prices are well maintained at the full list. Steam and forge coals are in active request, with supplies barely equal to the demand, and good qualities readily fetching about 9s. at the pit. Gas coal contracts are being settled on the basis of about 9s. for the commoner sorts, and 9s. 6d. up to 10s. for the better qualities at the pit's mouth. Engine fuel is rather more plentiful in the open market, increased quantities coming in from Derbyshire and Yorkshire, but Lancashire collieries are generally short of supplies, and their prices are very firm at 6s. 6d. to 6s. 9d. for best; 5s. 9d. to 6s. for medium, and 5s. 3d. to 5s. 6d. common sorts at the pit's mouth.

Shipping is only moderate, with ordinary steam coal averaging about 9s. 6d. Garston Docks; 10s. High Level, Liverpool, up to 10s. 6d. on the Manchester Ship Canal.

THAMES.

(*From our own Correspondent.*)

MESSRS. W. H. ALLEN, SON & CO., of Bedford, have lately constructed one of the largest self-contained surface condensing plants yet made in the United Kingdom. It has a tube surface of 2,000 lbs. of steam per hour with a vacuum varying between 27 in. and 28 in. The shell and frame is of cast iron, and the tube plates are of rolled naval brass and tubes of solid-drawn brass. The tubes are fixed into the plates with screwed ferrules and tape packing. The condensing water passes into the condenser at the bottom and out through the top. The air and circulating pump-engine is inverted with 10 in. by 17 in. diameter cylinders and 14 in. stroke. Two fly-wheels are fitted to the crank shaft. There is a double acting circulating pump with a diameter of 19 in. and 14 in. stroke. The speed of the engine when the pump is working at its full capacity is 60 revolutions. The weight of the whole is 390 cwt.

Messrs. John Steward and R. & H. Green, who build so many steel barges, should have a fair opportunity of some of the twelve steel barges for which the Belfast Harbour Commissioners are inviting tenders. They are designed to carry twenty boxes 6 ft. 6 in. long, 4 ft. wide, and 4 ft. 9 in. deep. The material is to be Siemens-Martin mild steel, to be suitable in quality and tests to Lloyd's requirements. The contractor has to keep them in repair for three months after completion. Preference will be given to the contractor who undertakes to deliver the barges within the shortest date after acceptance of tender.

Very many of the engineering firms on the Thames are at present turning out some of their old cutting tools and replacing them with American or those with the latest improvements in this country. It will be satisfactory for some of those to know that Messrs. Schischkar & Co., of Birmingham, have just put on the market a very excellent capstan lathe. It has a four-speeded cone 8 in., 10 in., 12 in., 14 in. in diameter by 3½ in. face. The spindle has parallel necks in long gun-metal bushes. There is a self-centreing clinch with jaws to carry from 1¾ in. to 1 in. diameter iron and a hole through the spindle to admit of any length of iron. The bed is 6 ft. long, 12¼ in. wide across the face. It is fitted with a saddle or carriage 3 ft. long. The revolving table is 16 in. diameter, fitted with four tool holders. It is revolved by hand.

Messrs. A. & J. Thompson, of Custom House, have a very good arrangement of steam whistle which they are fitting in many steamers. In most steam whistles there is a long pipe from the boiler to the whistle, and in the ordinary arrangement this pipe often gets filled with water. The consequence is that the signal is by no means instantaneous; in fact, a considerable time elapses between the pulling of the whistle cord and the sound of the whistle. It is of the utmost importance that an immediate and clear sound from the whistles and sirens of steam vessels should be obtained. Moller's drainage valve is designed to obviate these defects. It will be seen that in this type of drainage valve the passage on the right side, which is the passage from the boiler, is closed by a valve, but the upper passage to the whistle is always open to the left lower drainage passage, and there can thus be no accumulation of water in the whistle pipe. The instantaneous, clear, and full sounding of the whistle is thus rendered an absolute certainty. To obtain this certainty is of great importance, as the safety of the vessel is in many cases dependent on the means of prompt signalling. The North German Lloyd Co. have had them fitted to their fleet, and many vessels in the German Navy have also been fitted with them.

Messrs. Caird & Raynor are very full of work at the present time with heaters, evaporators, and condensers. Lately they made an excellent steriliser for the purifying of water.

BELFAST.

(*From our own Correspondent.*)

THE past month has been exceptionally quiet here in regard to shipbuilding and engineering, inasmuch as there is not a single launch from any of the yards, nor even a trial trip to report. As we said last month, the extensive repairs and alterations to so many large vessels have evidently arrested the progress of new work; besides, the limited number of hands of a certain class obtainable, coupled with the slow delivery of material, combines to obstruct the output of new work, which is to be much regretted.

Work on board the s.s. *Oceanic* is going on apace, her masts and funnels being now almost complete. These enormous funnels are the subject of general remark. Owing to their extreme height, two of the top courses of plating have had to be built on their place in sections, as the crane could not reach them. We understand the height of these funnels, from top of furnace-grate bars to top of funnel, is 120 ft., which should enable the smoke to be carried well clear of any part of the steamer's deck. Every kind of work on board is being hurried on as fast as possible, so that by another month she should be fairly well advanced towards completion.

The s.s. *Germanic* is now being finished up after undergoing a most extensive overhaul, and with her fresh coat of paint and new fittings will almost look like a new vessel; but she does look small and insignificant when lying alongside her sister ships, the *Medic* and *Afric*, her funnels being scarcely seen over the deck houses of these two leviathan steamers, which still lie in Abercorn Basin. The *Medic*, however, is getting well on towards completion, whilst the *Afric* has returned for refrigerating machines and some other alterations, which are well advanced; and it is expected these two vessels will be on their old stations before long.

The P. & O. s.s. *China* has not yet gone into graving dock, but a great many hands are employed on her, making preparations for her occupation of the graving dock. Her repairs will take months to execute.

The new s.s. *Winifredian* still lies in Abercorn Basin, and there seems to be a great scarcity of men to carry out the work required on her. As already mentioned, Messrs. Harland & Wolff, Limited, who have all these repairs on hand, find it very difficult to procure sufficient men for their requirements, although at the present time they have in their employment upwards of 9,000 men; but certainly, unless more progress is made with the new work in hand, the output at end of year will be curtailed very much.

Messrs. Workman, Clark & Co., Limited, have still the s.s. *Ping Suez* in hand, but she is nearly finished. They have also the s.s. *Brisgravia*, for the Hamburg-American Co., almost completed. She will leave here in the course of a week or ten days. This firm (Messrs. Workman, Clark & Co., Limited), have also had a large number of ship and engine repairs recently, so much so that they are at present making extensive additions to their repairing works at Abercorn Basin, in order to meet their requirements in this department, and we understand that when these extensions are completed they intend making all their own winches, windlass and steering gear for their steamers, which will mean employment for more men. This firm are also very much hampered for want of ironworkers in their building yard, but they have several vessels in a forward state for launching, and we hope to report some of these next month.

Messrs. MacColl & Co., Limited, are at present building a ferry-boat for the Belfast Harbour Commissioners, and they are also constructing cranes, &c., for use at the harbour. A deputation from the Belfast Harbour Board have again gone to London to seek the assistance of Government in making a suitable new dry dock, which would accommodate war vessels as well as these large liners, but so far their mission has met with little success. This question of dry dock accommodation will have to be faced at once, as the increasing wants of this port demand it, and surely there is enough money and energy to enable us to get it at no distant date. We might state that piling has commenced for the extension of the harbour on the south side of the river, and when part of this is done, so that the dredger can work, there will soon be a flotilla of barges, cranes, &c., at work. A great many of the new electric light poles, which are of malleable iron tube, are now completed. These look very neat with lamp on top, and when all are lighted will be a great advantage to the district on both sides of the river.

All the foundries and smaller engine works here keep well employed, consequently very few men who care to work are idle.

The Londonderry Shipbuilding Yard have commenced operations, and have got the keel of their first steamer laid. This vessel is being built to the order of Messrs. McVicker, Marshall & Co., of Liverpool, who are extensive shipowners, and has a dead weight of 6,200 tons, and measures 375 ft. over all, but they are now face to face with their first strike of labourers, who have demanded an increase of wages from 16s. to 20s. per week (not a bad rise if they can obtain it), but as there is plenty of unskilled labour in and around this district, we anticipate this strike will be of short duration.

The paddle steamer *Slieve Donard*, which belonged to the Belfast and County Down Railway, and ran to Bangor and other holiday resorts along this coast, left this port during the month, having been sold to Bristol owners. It is reported that Messrs. G. & J. Burns intend running a passenger service direct from Glasgow to Bangor, Co. Down, which will increase the popularity of this growing suburb and be a splendid sea trip for excursionists at a cheap fare.

Messrs. Ramage & Ferguson, Limited, Leith, have received an order to build a Twin-screw steamer for South Africa, and also for a cargo steamer to carry 1,900 tons deadweight.

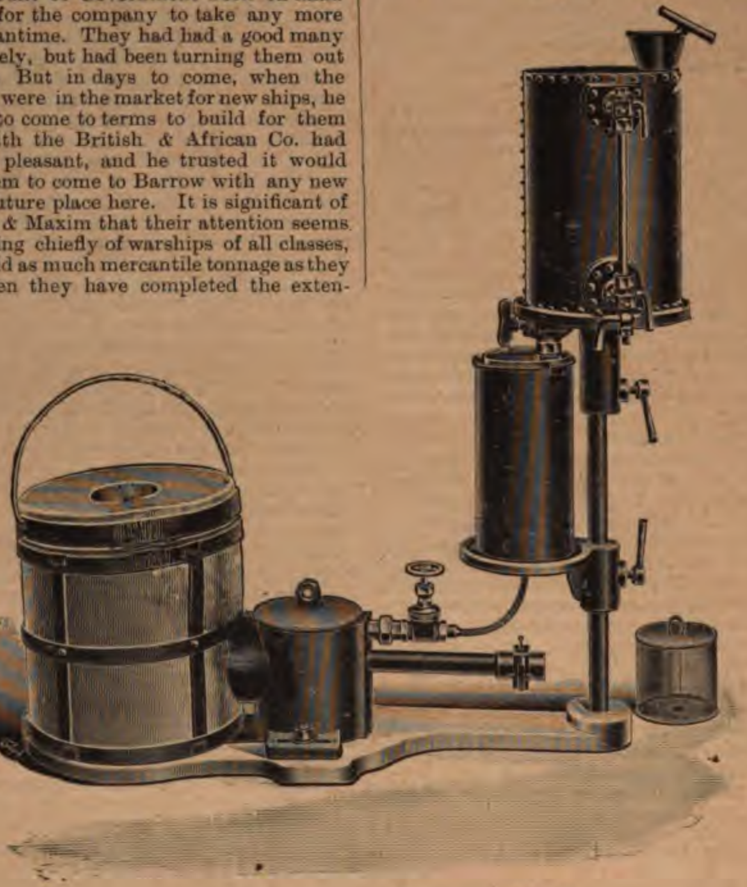
NORTH-WEST OF ENGLAND.

(*From our own Correspondent.*)

Barrow.—There is great briskness and life in the shipbuilding and marine engineering trades of Barrow. No new orders have been booked during the month, but very little need for them exists, seeing the very large orders already held. Yet more of the same sort will be welcomed and are expected, but in the meantime the works are being gradually enlarged, and being fitted up with the newest and most modern appliances; electricity is taking the place of steam-engines for motive power, and a general expansion is taking place at the works of Vickers, Sons, & Maxim, with the view not only of making the naval construction works more complete, but of embracing within its operations many new departments that will make the concern more and more dependent on its own resources in a great variety of ways. One of the most important developments taking place at present is one for the manufacture of gun mountings. This, when complete, will be nearly as large a department as that of marine engineering itself, and it certainly is a department which is exceedingly busy and has orders before it which will ensure very great activity for a very long period of time to come. Preparations are being made for the launch of H.M.S. *Vengeance* on July 25th. This will be a red-letter day in Barrow, as it will not only be the first battleship ever built at Barrow, but will be the first battleship ever built and fully equipped by one firm. The launch of the Pacific liner *Ortona* will very possibly take place before that of the *Vengeance*, as her owners have need of her, and the greatest possible progress is being made with her construction. She is plated, and the riveters are very busy with her, while the engineers are at work in the bringing out of her stern tubes. The *Euryalus*, first-class cruiser, will go down on the berth vacated by the *Ortona*, and the *King Alfred*, first-class cruiser, will go down on the berth now occupied by the *Vengeance*. The *Hogue*, first-class cruiser is well in frame, and the Japanese warship, which is a monster, having a very great beam and bearing frames, is gradually assuming shape. By the time she is launched, it is probable much progress will have been made with the construction of the new lock at Ramsden Dock, powers for the making of which are being obtained by the Furness Railway Bill, now before Parliament, which Bill has passed through its crucial stages without opposition. This lock will have a width of 100 ft. and a depth of 30 ft., and will be built so as to be used as a graving dock. As such it will be exceedingly useful for the repair of heavy tonnage ships, and will doubtless bring to Barrow much of the repairing trade. It is possible to launch the Japanese battleship and dock her safely by means of the present lock at Ramsden Dock, but the greater depth of water provided on the sill of the new lock will be required before she can leave Barrow when all her weight gets on her. The great difficulty Barrow shipbuilders have at present is the great scarcity of house accommodation for their workmen. As stated last month, 1,000 new houses are to be built by the company on Walney Island, but this is only part of a bigger scheme, as it is intended to bring into existence a new watering place, Walney-on-the-Sea, under the auspices of the Isle of Walney Estates Co., Limited, which has just been registered with a capital of £100,000, all of which is subscribed. The promoters are Messrs. Albert Vickers, of Vickers, Sons, & Maxim; James Dunn, late of the Admiralty, and now with Vickers; Alexander Adamson, manager of the Naval Construction Works; George Henry Pattinson, of Windermere; and John Poole. The work which this syndicate has in hand has already begun. It gives promise of one of the most interesting enterprises ever entered upon by gentlemen mainly associated with the shipbuilding trade, but there is a general belief that the scheme is a sound one, and only needs courage and determination to make it a great success financially.

The powerful hydraulic 100-ton crane situate alongside the engine and boiler shops of the Naval Construction Works, built by Sir W. Armstrong & Co., of Newcastle-on-Tyne, for the Furness Railway Co., has been owned by the latter ever since it was put up, until the present, but it has now been arranged to sell it to Vickers, Sons & Maxim, by whom it will be solely used in future. The work of improving its lifting power has been undertaken by its new owners, and by means of strengthening its radial base, and increasing its multiplication of power by adding other pulleys to the blocks, it will be made to lift 120 tons with ease. It has been found necessary to give the crane this additional power owing to the heavier weights to be lifted nowadays for the big battleships and cruisers.

Some idea may be obtained of the orders held by Messrs. Vickers, Sons & Maxim, Limited, at their Barrow works, and their position in reference to the acceptance of new mercantile orders, from the speech delivered by Mr. A. Adamson, the manager of the Naval Construction Works of the company on the occasion of the launch of the s.s. *Bornu*, for the British & African Steamship Co. He said he was very sorry that they were likely to come to an end, for the present time at least, of their orders for the British & African Co. They had been building ships for them for 10 years. The British & African Co. were one of the first customers of the Naval Construction Co., and since then they had always had business connections with them, being seldom without a British & African boat in the yard. They were pleased in one way, but sorry in another, that the great amount of Government work on hand made it quite impossible for the company to take any more merchant orders in the meantime. They had had a good many merchant ships on hand lately, but had been turning them out as quickly as they could. But in days to come, when the British & African Company were in the market for new ships, he hoped they might be able to come to terms to build for them again. Their relations with the British & African Co. had always been of the most pleasant, and he trusted it would always be a pleasure to them to come to Barrow with any new orders they might in the future place here. It is significant of the policy of Vickers, Sons & Maxim that their attention seems to be directed to the building chiefly of warships of all classes, but they propose also to build as much mercantile tonnage as they can possibly undertake when they have completed the exten- have to their already great yard now going on, and when they sions put down the new machinery which a bigger tonnage of output will necessitate. At present they have the British & African steamer *Bornu* to complete, and the Pacific Steam Navigation Co.'s steamer *Ortona* to launch and complete, and the *Clan Buchanan* to triple, and then their commercial tonnage on order for the present will be completed. It will not be long before other commercial work is undertaken if present indications may be taken as a criterion.



LIQUID FUEL CRUCIBLE FURNACE. FIG. 1.

West Cumberland.—The renewal of attention to the Whitehaven Shipyard, which it has for long been the hope of West Cumberland people to re-form into a company, seems again to have lapsed, as no local capitalist seems disposed to come forward to give the scheme "a leg up." Whitehaven is a moribund place, its population is on the decline, and its sons and daughters are making their exit to other places where there is greater scope for their energies than in the dead-alive town of their birth. Yet at one time Whitehaven was of as much importance as Liverpool, and was about the only port in the North-West of England that devoted any attention to the *building of ships; but that day* has passed, and, with the great yard at Barrow, and the smaller yards at Maryport and Workington, Whitehaven has been closed, in all probability, never to be opened again as a shipbuilding centre. There is a steady and brisk trade being done at Messrs. Williamson's yard at Workington, and orders are well held for various types of vessels of small tonnage, prospects being good for a constant run of orders. At Maryport business is fairly well maintained, but there is not a deal of spirit or enterprise shown in the work carried on here. A few orders are on hand and others are being arranged for.

The Duddon.—Shipbuilding at Duddon, on the estuary of that name, has never been carried on on a large scale, but it is noteworthy that, while iron ships have given way to steel ships, Duddon is a place where wooden ships have not yet given place to iron ships, although, it is strange to say, the port of Duddon is the most actively employed in iron ore exports of any port in the Kingdom. The Duddon Shipbuilding Co is now "busy" in building a three-masted schooner, 105 ft. between perpendiculars, of British oak. This wooden-walled trader will be locally owned, and will, it is probable, be followed by other orders, as schooners of this sort carrying a few hundred tons are profitably employed in the coasting trade, especially in the case of ports where only shallow-water approaches exist.

Shipbuilding Material.—There is a very brisk and active demand for all descriptions of shipbuilding material, and in many cases builders are being very much delayed in the work in hand by the difficulty they have in getting deliveries of specifications supplied to makers. The consequence is that the mills are all very briskly employed in the production of both heavy and light plates, and makers have work in hand which will keep them employed for a considerable time to come. Prices remain at satisfactory figures. Heavy plates are at £7 1s. 3d., and angles, which are also in large demand, are at £6 13s. 9d. There is great need on this coast of a modern angle mill built on economically workable lines, not only as means of supplying local but other buyers, such as those at Belfast, Glasgow, the Mersey, the Dockyards, and elsewhere. And the probabilities are that Barrow will be the place where this mill will be put down. The demand for heavy and light steel castings for shipbuilding and marine engineering purposes is well maintained, and this is one of the most actively employed and most profitably worked departments the Barrow Steel Co. possesses. There is a good demand for shipbuilding material sundries, and it is more and more certain every day that these sundries will gradually be produced at Barrow, as there is a tendency to locate here all the minor industries which are kindred to, and feeders of, the bigger establishments.

The Hematite Trade.—There is a marked improvement in the hematite pig iron trade this month, and indications are presenting themselves on every hand that the demand for metal will soon exceed the supply, especially as the former is growing, and it is impossible under present conditions to increase the latter, owing to the scarcity of iron ore and a shortage in the delivery of coke from the Durham and Burnley ovens. Makers are quoting 64s. to 66s. per ton for mixed Bessemer Nos. net f.o.b., and warrant iron is at 64s. 10d. net cash sellers, 64s. 9d. buyers. There is every prospect of America becoming a large buyer of hematite. If so, she can only get supplies from warrant stores, which stand at present at 226,000 tons. Makers are so well sold forward that they have no metal to offer for sale in anything like large parcels for prompt delivery.

Shipping.—The shipping trade is much more actively employed than was the case in the early months of the year. The exports of pig iron from West Coast ports this year represent 183,573 tons, and of steel 194,729 tons, showing a decrease in the former of 2,828 tons, and in the latter of 18,618 tons. It is probable shipments will largely increase before Midsummer is reached, as the foreign demand is likely to be of considerable volume. Freights are satisfactory, and profits good, but one serious drawback is the dearness of coal. This represents a greatly increased charge on steamship owners.

LIQUID FUEL CRUCIBLE FURNACE.

A SIMPLE, compact, and efficient device, in a portable form, by means of which a high temperature can be readily and quickly produced for any purpose, such as the fusing of metals, will, no doubt, be found a great convenience on board ship and in engineering works and shipyards.

The Bickford Burner Co., of Camborne, Cornwall, have given the subject of liquid fuel as a heating agent a considerable amount of attention, and have devised some appliances which we understand give very good results.

We have now the pleasure to illustrate (Fig. 1, page 130) and describe the patent liquid fuel crucible furnace which has just been placed on the market by the Bickford Burner Co., and which has been primarily designed for brass melting, but it will be readily understood that it is capable of dealing with other metals.

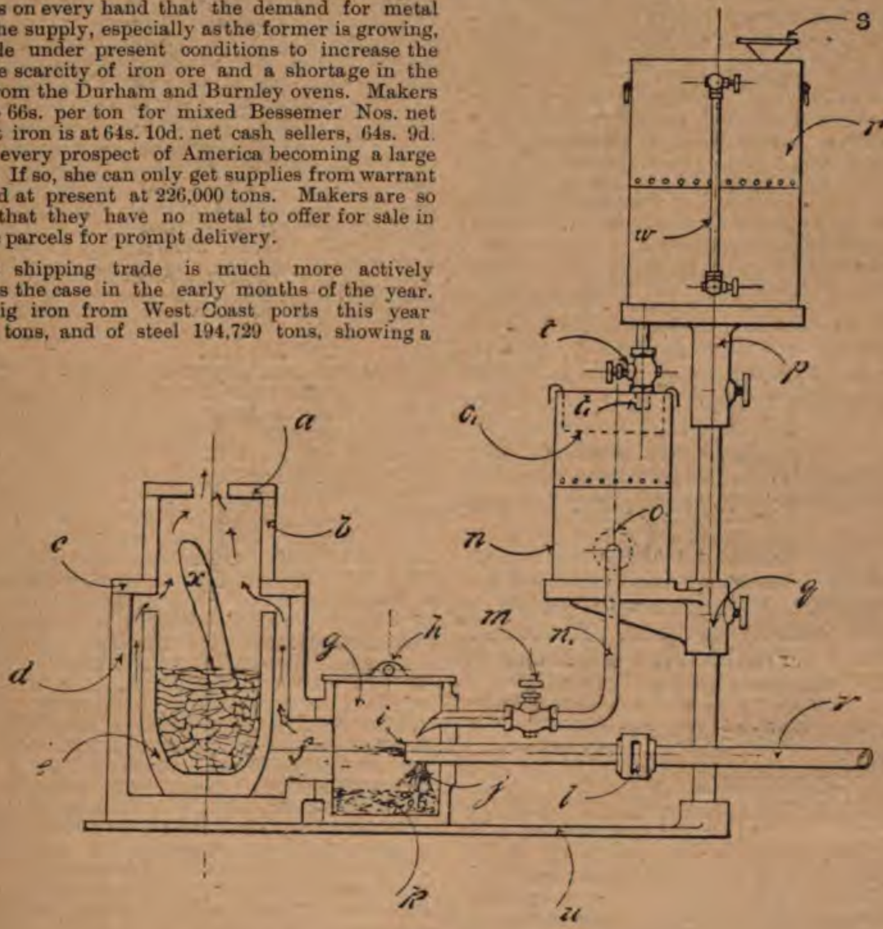


FIG. 2.

The adjoining illustration (Fig. 2.) shows the apparatus in part section. The oil is stored in an air-tight reservoir r and flows through a cock t into the filter tank n containing two filters o, o^1. As the only inlet for air into the reservoir r is through the pipe t^1 when the end thereof is not submerged, the flow from the reservoir stops when the oil level in the tank n reaches the end of the pipe t^1, and thus the level of the oil in n remains practically constant. From n the oil flows through the flexible steel hose n^1 and stop-cock m to the oil-spout, and thence round the air-nozzle i to the slot j, by the air issuing from which it is blown to the bottom of the combustion chamber g, amongst the broken brick k.

The resulting flame is blown through the hole f into the furnace d around the crucible e and up through the warming cylinder *b*, so as to heat the overlapping charge *x*. Air is supplied from any convenient source, through the slide-valve *l*. When the warming cylinder is not required, the small lid *a* is placed on the large lid *c*. The cover *h* of the combustion chamber *g* and rim of the latter are machine-faced so as to make a flame tight joint; the cover is not fastened down in any way.

To start the device, all that is necessary is to lift the lid of the combustion chamber and place therein a bit of lighted waste or other inflammable material, then turn on the oil and air valves *m* and *l*, and as soon as the oil catches alight, replace the lid of the combustion chamber and adjust the oil till the flame appears about four inches above the cover.

The objection to liquid fuel apparatus that is commonly, and in many cases justly, urged is that it is liable to choke and is complicated to work. It is an interesting fact to note that in this device there is no pipe or hole through which the oil passes which is less than ¼-inch bore, and, further, the oil passes through a double filtering arrangement.

The makers put forward an interesting comparison between coke and oil in the fusion of brass. The quantity they take is 40 lbs.: to fuse which, ¼ cwt. of coke at 1s. 3d. per cwt., costing 3·75d., must be used; to which must be added the cost of two hours' labour, including carrying coke and laying and clearing fires, equal to 8d.—together 11·75d. If carried out by oil, the cost will be ½ gallon of creosote heavy green oil 1d., and ½ hour's labour 2d., together making 3d. So that the oil fuel only costs a quarter the cost of coke.

The Bickford Burner Co. also make a petroleum Bunsen burner, which has been specially contrived for steam-raising purposes. It is extremely simple in construction and can be easily regulated. The burner requires neither steam nor air-blast and can be started all cold in from five to seven minutes.

OBITUARY.

ALEXANDER STEPHEN, SHIPBUILDER.

THE death took place in Glasgow on the 19th ult. of Mr. Alex. Stephen, the senior partner in the well-known Clyde shipbuilding and engineering firm of Messrs. Alex. Stephen & Sons, Linthouse. About six weeks prior to the sad event, the deceased gentleman, who was in his 67th year, contracted a severe cold which developed into influenza, and although apparently recovering, he had a relapse and gradually sank, until he finally succumbed on the morning of the 19th, within his town residence at Park Terrace. The late Mr. Stephen came of a shipbuilding race; his father, Alexander Stephen, being the founder of the shipbuilding business of A. Stephen & Sons, long established at Dundee, and subsequently also of the offshoot business on the Clyde, of which the deceased gentleman eventually became head partner. He was born at Arbroath on the 25th April, 1832, having thus before his death attained his 67th year, and was one of the oldest living Clyde shipbuilders. He was educated in Aberdeen and Dundee, and studied subsequently at Edinburgh University, where, with the practical sagacity which has marked his highly successful career all through, he gave special attention to the subjects bearing most directly on his future profession. His apprenticeship, as a shipwright, was commenced under his father in Dundee, in 1849, exactly 50 years ago, and he was looking forward to the celebration of his working jubilee with pleasurable anticipation previous to his illness. In 1852—three years later—*he came to Glasgow,* where he joined his father in the business at Kelvinhaugh, still existing as the Kelvinaugh Slip-dock and Shipyard. The business at Dundee was then, and for long, carried on by his father and brother William. In 1861 the deceased Mr. Stephen created a stir in shipbuilding circles by introducing a style of shipbuilding known afterwards as the "composite" system, where iron took the place of wood in several parts of the ship, especially in the framework, and his lead in this new departure was followed, not only by his fellow shipbuilders on the Clyde, and in England, but by the Admiralty as well. Finding, in the course of time, the premises at Kelvinhaugh too limited, and to meet the growing demand for steam vessels in ocean navigation, the firm bought in 1868 the fine old estate of Linthouse, where works and plant for both engineering and shipbuilding were erected, which are to-day amongst the finest and most complete on the Clyde or elsewhere. Mr. Stephen was a man who gave close and constant attention to his business, and to this marked characteristic of the man is due mainly his great success. He was one of the very few who were at once heads of firms and able to make their ship-models with their own hands. His vessels became known not only for soundness of construction, but for beauty of form, and many of them have had eventful histories. One, for instance, after doing splendid service as the *Sea King*, in the peaceful capacity of a China tea clipper, was converted into the notorious Confederate cruiser *Shenandoah*, and ultimately became the Sultan of Zanzibar's yacht. Among mail steamers built by Mr. Stephen were some for Brazil, and in 1872 the Emperor of that State decorated him with the order of a "Knight Officer of the Rose." Mr. Stephen's firm has also all along built for important shipping concerns, such as the Hamburg-American Co., Messrs. Sloman (Hamburg), the Anchor Line, the Clan Line, and the Allan Line, for the last of which they have on hand at present a magnificent twin-screw steamer of over 10,200 tons. A conspicuous feature of the yard has always been the large travelling crane which traverses the building berths for the purpose of putting engines and boilers on board. It has been the practice of the firm for years to launch their boats, except in special instances, with engines on board. One very serious and lamentable disaster befel the firm twenty years ago, when the *Daphne* toppled over on leaving the ways, several hundred men being drowned. It was a catastrophe that afflicted Mr. Stephen very sorely, and from which he did not recover for many a year. The deceased gentleman leaves a widow and three sons and three daughters to mourn his loss, most of whom are married—the two eldest sons, Mr. Alexander E. Stephen and Mr. Fred. J. Stephen, being partners in the old-established firm at Linthouse. About eleven years ago, when his sons were beginning to take share of the cares of the business, Mr. Stephen purchased the pretty sylvan retreat known as Kelly Estate, at Wemyss Bay, from the trustees of the family of the late James Young, of paraffin fame, where he demolished the old mansion-house and built himself a beautiful home, where he spent the greater part of the years since its completion. His close application to business, and the pleasure he took in his work, kept him away from what is commonly called "public life," but he found time for some good service in this direction also. He was the first chairman of the Govan School Board, where he sat for many years, and in 1882 and 1883 he was Lord Dean of Guild for the city, and filled both positions with credit and distinction. He was for some years chairman of the Technical College, Glasgow, and was held in high esteem by all leaders of education in the city.

The New Liverpool Dock is 925 ft. long, 94 ft. wide at entrance, and the sill 13 ft. 3 in. below O.D.S. The capacity of the dock is 3,226,648 cubic feet, and for emptying the dock there are three 51 in. centrifugal pumps, capable of pumping about 1000 tons a minute. The 80,000 tons of water in the docks were taken out in an hour and forty minutes.

Lowestoft Low Lighthouse.—This lighthouse is being moved 250 ft. further inland by a local contractor, under the supervision of a representative of the Trinity House, in consequence of the encroachment of the sea upon that portion of the eastern coast between Harwich and Great Yarmouth. This will be the third time the lighthouse has had to be removed further back.

LAUNCHES AND TRIAL TRIPS.

LAUNCHES—English.

Northwood Ho.—On April 8th there was launched at Hull, for Messrs. S. T. White & Co., Limited, of Hull, an iron steam ketch, of about 152 tons gross, named the *Northwood Ho.*

Britannia.—On April 10th there was launched at Plymouth, for the Volonga State Co., of London, a wooden sailing schooner, of about 106 tons gross, named the *Britannia.*

Arcadia.—On April 15th there was launched at South Shields, for an Austrian firm, a steel schooner-rigged steamer, of about 3,143 tons gross, named the *Arcadia.*

Manu.—On April 24th there was launched at Sunderland, for Hijos de Astigarraga, of Bilbao, a steel schooner-rigged steamer, of about 2,060 tons gross, named the *Manu.*

Gottfried.—On April 25th there was launched at Sunderland, for Mr. G. Sjoberg, of Malmö, a steel schooner-rigged steamer of about 1,284 tons gross, named the *Gottfried.*

Tullochmoor.—On April 25th Messrs. William Doxford & Sons, Limited, launched at Pallion, Sunderland, the cargo turret steamer *Tullochmoor*, built to the order of Messrs. Walter Runciman & Co., and the directors of the Moor Line, Limited, Newcastle. The *Tullochmoor* is a duplicate of the *Peachmoor*, built by Messrs. Doxford to the order of the same firm. Her dimensions are 340 ft. in length; 45 ft. 6 in. in breadth; and 27 ft. 3 in. in depth, moulded. She has a carrying capacity of about 5,800 tons, on a draught of 22·2 ft. Her gross tonnage is 3,480, and her net tonnage, 2,220. The engines are built also by Messrs. Doxford, and have 26 in., 42 in. and 68 in. cylinders, with 42 in. stroke.

Conqueror.—On April 26th Messrs. Willoughby Brothers, Limited, launched at Plymouth, a steel screw vessel, the *Conqueror*, built for Mr. George Etheridge, of London. The dimensions of the vessel are:—Length, between perpendiculars, 85 ft· 2 in.; breadth, 18 ft.; depth, 10 ft. 5 in. The engines are compound surface-condensing, having cylinders 17 in. and 34 in. diameter, 21 in. stroke. The hull and machinery were built under Lloyd's special survey.

Sophron.—On April 26th there was launched at Hull, for the Standard Steam Fishing Co., Limited, of Grimsby, an iron steam ketch, named the *Sophron.*

Manchester Port.—On April 26th there was launched by Messrs. Palmer's Shipbuilding and Iron Co., Limited, from their Jarrow yard, a finely modelled steel screw cattle and cargo steamer named the *Manchester Port*, built to the order of the Manchester Liners, Limited, of which Sir Christopher Furness is chairman. The vessel is built expressly for the Manchester Liners' service from the Manchester Canal to Canada, and when fully laden she will be of a draught perfectly suitable for the canal. She is six feet longer than the *Manchester City*, at present running, and will be the longest boat which has as yet used the Manchester Ship Canal. Her dimensions are, viz., length 467 ft. by 52 ft. beam and 39 ft. depth, has four masts, and is rigged fore-and-aft with telescopic topmasts and funnel to suit the Manchester Canal bridges, and has been built under special survey to take the highest class in Lloyd's registry. She is of the three-decked type, with two steel decks laid all fore-and-aft, and has an iron shelter deck specially strengthened considerably in excess of Lloyd's requirements for the Atlantic trade, extending over the whole length, and above this is a bridge deck 130 ft. long. All the available space under the shelter deck, and along each side under the bridge deck, is fitted throughout to pass American and Canadian regulations, with the most improved and modern arrangements for carrying about 700 head of cattle. The accommodation for the saloon, captain's, and spare staterooms, &c., is arranged on the bridge deck in a large steel deckhouse, with separate houses for officers and engineers. The seamen and firemen are housed under the shelter deck forward, and the cattlemen's quarters are under the shelter deck aft. A cellular double-bottom is fitted all fore-and-aft for water ballast, and also four separate tanks under engine and boiler space for fresh water for supplying cattle. Water ballast is also arranged to be carried in a deep cargo tank and in the after peak, giving the vessel a total water ballast capacity of over 2,000 tons. The displacement of the vessel is about 14,500 tons, and she is divided into nine watertight compartments by means of eight steel bulkheads, all of which extend to the upper deck. Each compartment is fitted with complete grain divisions. A most complete system of ventilation has been arranged to ensure the safe carriage of cattle, grain, or other cargoes. The vessel has 10 hatches, 12 powerful steam winches, and 20 derricks provided for the rapid loading and discharging of cargoes. Aft of the engine-room the 'tween decks are insulated and fitted with the necessary refrigerating plant, specially arranged for the conveyance of fresh beef, mutton, poultry, fruit, butter, &c. A powerful steam windlass is fitted forward for working the cables, and a combined hand and steam-steering gear of special design is fitted in a large steel wheelhouse on the after end of the shelter deck. The vessel is lighted throughout by electricity. The engines are also being constructed by the Palmer's Co.; they are of the inverted triple-expansion type, having cylinders 30 in., 50 in. and 81½ in. by 54-in. stroke, steam being supplied by three double-ended boilers 14 ft. 6 in. diameter by 17 ft. 6 in. long, with a working pressure of 180 lbs. All the shafting is of hydraulic compressed steel, and is considerably in excess of Lloyd's requirements. The propeller is of manganese bronze, and all the auxiliary machinery is of the most modern type.

Undaunted.—On April 27th there was launched at Selby, for the Grimsby Union Steam Fishing Co., Limited, of Grimsby, an iron steam ketch, named the *Undaunted.*

Barton.—On April 27th Messrs. Ropner & Son, Stockton-on-Tees, launched a steel screw-steamer of the following dimensions:—Length between perpendiculars 330 ft.; breadth extreme, 47 ft.; depth, moulded, 27 ft. 4 in. The steamer has been built to the order of Messrs. Webster & Barraclough, West Hartlepool, and is off the three-decked rule, fitted with the builders' patent trunk, full poop, bridge, and topgallant forecastle. The saloon and cabins for captain and officers will be fitted up in the poop, the accommodation for engineers in iron houses on the bridge deck, and for the crew in the forecastle, as usual. She has double-bottom on the cellular principle for water ballast, and will carry about 5,750 tons on Lloyd's summer freeboard, on a light draught of water. She will have all the most recent appliances for the expeditious and economical loading and unloading of cargoes, has direct steam windlass, steam-steering gear amidships, with powerful screw gear aft, six large steam winches, to which steam is supplied by a large horizontal multitubular donkey boiler, stockless anchors, &c. She will be fitted with a set of triple-expansion engines by Messrs. Blair & Co., Limited, having cylinders 24 in., 40 in., 65 in., by 42 in. stroke. The christening ceremony was gracefully performed by Miss Mary Webster, daughter of Mr. E. A. Webster, of Wolviston Hall, who gave her the name of *Barton.*

Oriflamme.—On April 27th this vessel was successfully launched by Messrs. Armstrong, Whitworth & Co. Limited, from their Walker Shipyard. She is the first of three vessels being built by that firm to the order of Messrs. Lane & Macandrew, of London, on behalf of MM. Desmarais Frères, of Paris, and is specially designed for the carriage of petroleum in bulk. This vessel and her sister ships are being constructed under the immediate supervision of Messrs. Flannery, Baggallay & Johnson, of London and Liverpool; and are to obtain the highest class of Bureau Veritas, and to conform with the Suez Canal regulations for oil steamers. The principal dimensions are:—Length, 347 ft.; breadth, 45 ft.; depth, moulded, 29 ft. 6 in.; and the engines, constructed by the Wallsend Slipway and Engineering Co., have cylinders of 24 in., 40 in. and 64 in., taking steam from two large single-ended boilers working at 160 lbs. pressure, and having a heating surface of about 5,300 sq. ft. It is expected that this machinery will prove capable of propelling the vessel at a speed of 10½ knots when laden with a deadweight of 5,500 tons. Electric light is fitted throughout the vessel, and the pumping installation is especially handy and powerful, and capable of dealing with oil cargoes with great rapidity.

Parana.—On Thursday, April 27th, Messrs. W. Gray & Co., Limited, launched a fine steel screw-steamer, which they have built to the order of Messrs. Morel, Limited, of Cardiff. She will take Lloyd's highest class, and is of the following dimensions:—Length over all, 336 ft.; breadth 47 ft.; depth, 24 ft. 10 in., with full poop, bridge, and topgallant forecastle. A tasteful saloon and the captain's and officer's rooms will be fitted in a large house on the bridge, and the engineer's rooms will also be on the bridge. The hull is built with web frames, and double bottom under each hold for water ballast. Two large patent donkey boilers, seven steam winches, steam-steering gear amidships, hand screw gear aft, patent direct steam windlass, iron longitudinal grain divisions, stockless anchors, and a complete outfit will be fitted for a first-class cargo boat. Fine triple-expansion engines are being supplied by the Central Marine Works of Messrs. W. Gray & Co., Limited. They will develop over 1,200 H.P. The cylinders are 24 in., 38 in., and 64 in. diameter, with a piston stroke of 42 in. Steam will be supplied by two large main boilers, at a working pressure of 160 lbs. per square inch. The vessel has been constructed under the superintendence of Mr. C. E. Kendall on behalf of the owners, and the ceremony of christening her *Parana* was gracefully performed by Miss Winifred Fea, youngest daughter of Mr. J. P. Fea, J.P., West Hartlepool.

Weissenfels.—On Thursday, April 27th, Messrs. Wigham, Richardson & Co. launched from their Neptune Shipyard the s.s. *Weissenfels*, which they are constructing to the order of the Deutsche Dampfschifffahrts-Gesellschaft "Hansa," of Bremen, for their Eastern service. The steamer is 370 ft. in length by 46 ft. beam by 30 ft. deep, and is being fitted with quadruple-expansion engines, balanced on the Yarrow, Schlick & Tweedy system, being the eighth set of engines built on this system by Messrs. Wigham, Richardson & Co., for the "Hansa" Co., and there are two more in course of construction. The vessel, which has a limited amount of passenger accommodation, has teak decks, and will be very completely provided with all the most modern appliances for handling her cargo most quickly and economically. The christening ceremony was gracefully performed by Miss Phyllis Young, of Tynemouth.

India.—On April 28th Sir Raylton Dixon & Co., Limited, launched from their Cleveland Dockyards, Middlesbrough, a fine steel screw-steamer, built to the order of the Austrian Lloyd's Steam Navigation Company, Trieste. She is built to Lloyd's highest class, spar deck rule. Her principal dimensions are 320 ft. by 44 ft. by 23 ft. 9 in., and she has a deadweight carrying capacity of about 4,600 tons on a light draught of water. The spar and main decks are of steel, and poop, bridge, and forecastle decks of pitch pine. She is fitted with water ballast in cellular double bottom, five watertight bulkheads, &c., with accommodation for captain and officers in houses on bridge deck. She will be fitted with triple-expansion engines by Messrs. Sir C. Furness, Westgarth & Co., Limited, Middlesbrough, having cylinders 25 in., 40 in., 66 in. by 45 in. stroke, supplied with steam by two large boilers working at 180 lbs. pressure. On leaving the ways she was gracefully named *India* by Signorina Fausta Vecchi, daughter of Signor Vico Vecchi, resident inspector for the owners.

Albatross.—On April 29th there was launched at Middlesbrough, for the Manchester and Liverpool Transport Co., Limited, of Manchester, a steel schooner-rigged steamer, of about 570 tons gross, called the *Albatross*.

Adalia.—On April 29th there was launched at Sunderland, for the Papayanni Steamship Co., Limited, of Liverpool, a steel schooner-rigged steamer, of about 3,848 tons gross, named the *Adalia*.

Cedric.—On April 29th Messrs. Cochrane & Cooper, Limited, launched from their Grovehill Shipyard a new steam trawler, of the following dimensions:—112 ft. by 21 ft. by 11 ft. 6 in. depth of hold, built to the order of the United Steam Fishing Co., Limited, Grimsby. Triple-expansion engines are being supplied by Messrs. C. D. Holmes & Co., Hull, and the vessel will be completed, ready for sea, with the most modern appliances for trawling. Mrs. G. Woods, of Grimsby, named the vessel *Cedric*, and after the ceremony the company adjourned to the office of the builders for luncheon.

Brimsnes.—On April 29th there was launched at North Shields an iron steam ketch, of about 160 tons gross, named the *Brimsnes*.

Isis.—On April 29th there was launched at Hull, for Messrs. Roberts & Ruthven, Limited, of Grimsby, an iron steam ketch, named the *Isis*.

Standard.—On April 29th there was launched at North Shields a steel steam ketch, of about 170 tons gross, named the *Standard*.

Emily.—On May 1st Messrs. Fellows & Son launched at *Southtown*, Yarmouth, the barge *Emily*, built by them for the Naval Ordnance Department, of Plymouth, and specially arranged to carry gunpowder, guns, &c. Her dimensions are:—Length, 86 ft.; beam, 20 ft.; depth, 7 ft.; and her carrying capacity 140 tons.

Caprice.—On May 5th Messrs. Summers & Payne launched at Southampton the 52-foot racing yacht *Caprice*, built to the order of Sir Henry Seymour King, M.P., commodore of the Royal London Yacht Club. The *Caprice* has been designed by Mr. Arthur E. Payne.

Abbey Holme.—On May 6th Messrs. Joseph L. Thompson & Sons, Limited, of the North Sands Shipbuilding Yard, Sunderland, launched this vessel. She has been built to the order of Messrs. Hine Brothers, of Maryport, and is the sixteenth vessel built by this firm for these owners. She is built to Lloyd's highest class, under their special survey on the spar deck rules, and is 358 ft. in length, over all, by 45 ft. 3 in. breadth, extreme, by 26 ft. 7 in. depth, moulded, and is constructed to have a large measurement and deadweight capacity on a moderate draught of water. The accommodation for captain, officers and engineers, saloon, separate messrooms for officers and engineers, and four spare berths for the accommodation of eight passengers, is in houses placed on the bridge deck; the crew, firemen, and petty officers being berthed in the topgallant forecastle. There is a large teak steering and chart house placed on top of the saloon house, the steering engine being fitted at the after end of the engine casings connected with controlling gear to the bridge. The poop and bridge space is entirely clear, and is arranged for the accommodation of cargo. The vessel has six watertight bulkheads, and the whole of the cellular double-bottom is fitted for the carrying of water ballast, which will also be carried in the after peak. The vessel is rigged as a two-masted fore-and-aft schooner, with telescopic masts, to enable her to go under the Manchester Canal bridges. The deck machinery is of a powerful description, and consists of eight steam winches with double derricks at the hatches, and a powerful steam windlass fitted on the forecastle head for the working of the anchors, which are of the patent stockless type; the deck machinery is supplied with steam by a large multitubular donkey boiler working at 180 lbs. pressure. The vessel is also arranged for the carrying of cattle, with ventilators fitted to suit the Board of Trade requirements, and has condenser for providing fresh water daily. As is usual with this line of boats, the vessel has a clipper stem ornamented with a neat figurehead (a likeness of Mrs. Robert Thompson) and trail boards. The vessel throughout has been specially constructed for the owners' Canadian, American, and other trades. The engines and boilers have been constructed by Messrs. George Clark, Limited, of Sunderland, the sizes of the cylinders being 23 in., 39 in., 66 in., with a stroke of 42 in., supplied with steam by two large multitubular boilers working at 180 lbs. pressure. The crank shaft is of forged steel from the Cyclops Works of Messrs. Cammel & Co., Limited, of Sheffield. The vessel and machinery have been constructed under the personal supervision of Captain George Brown, the owners' superintendent. The launch, which was effected by hydraulic power, was most successful in every way. The vessel was named by Mrs. Robert Thompson (Langham Tower), wife of the managing director of the builders' firm. There were also present Mr. Wilfred Hine, J.P. (one of the managing owners of the vessel), Mr. John McL. Hine, Captain George Brown, and a numerous company. It is interesting to note that Messrs. Hine Brothers first *Abbey Holme*, an iron sailing barque of 510 tons register, was built exactly thirty years ago on the same site as on which the present ship has been built. The first *Abbey Holme* had a long and successful career, but became a total loss at the mouth of the Tyne some years ago.

Kumara.—On May 8th there was launched from the East Shipbuilding Yard of C. S. Swan & Hunter, Limited, Wallsend, a large, finely modelled screw-steamer, which has been built to the order of the Shaw Savill & Albion Co., Limited, of London. The principal dimensions of the vessel are:—Length over all, 438 ft.; beam extreme, 54 ft. 3 in.; and depth, moulded, 32 ft. 10 in. to upper deck; and she has been built to take Lloyd's highest class three-deck rule. Above the upper deck a shelter deck has been fitted right fore and aft, at the fore end of which are berthed the crew and firemen, and at the after end provision has been made for carrying a number of steerage passengers. Accommodation for the officers, engineers, and a few first class passengers will be provided in large deck houses on the shelter deck, above which will be the captain's room, chart room, and a comfortable smoke room. One hold forward of the machinery space and one aft will be insulated for the carriage of frozen mutton, of which the steamer is intended to carry the large number of 100,000 carcasses, the refrigeration being done by two large freezing engines, which are being built by the Haslem Foundry and Engineering Co. The machinery, which is being built by the Central Marine Engine Works, West Hartlepool, will consist of a set of triple-expansion engines, having cylinders 32 in., 54 in., and 86 in. diameter, with a piston stroke of 54 in., steam being generated in five single-ended boilers, 15 ft. 6 in. diameter and 10 ft. 6 in. long, working at a pressure of 180 lbs. per square inch. During construction, the vessel has been under the superintendence of Captain McKirdy, the marine superintendent of the owners, assisted by Captain Scotland, and the machinery under that of Mr. T. Young, their superintendent engineer. On leaving the ways the naming ceremony was gracefully performed by Miss Scotland.

Nordpol.—On May 8th there was launched by the Northumberland Shipbuilding Co., Limited, at Howdon-on-Tyne, the steel screw-steamer *Nordpol*, built to the order of Messrs. Harloff & Boe, of Bergen, and designed to carry 6,300 tons. She is said to be the largest Norwegian-owned steamer yet built. The principal dimensions are:—Length, 352 ft.; breadth, 48 ft.; and depth, moulded, 28 ft. 5 in. She has been built to the highest requirements of Lloyd's registry, and also of the Norwegian Veritas. The propelling machinery has been constructed by Messrs. Richardson & Sons, Limited, of Hartlepool, and consists of a set of triple-expansion engines, having cylinders 24 in., 39 in., and 66 in. in diameter, by 45 in. stroke, supplied with steam by two boilers 16 ft. by 10 ft. 6 in. long.

Bornu.—On May 9th there was launched at Barrow, for the British and Africa Steam Navigation Co., of Glasgow, a steel schooner-rigged steamer, named the *Bornu*.

Crewe.—On Tuesday, May 9th, Messrs. Wood, Skinner & Co., Limited, successfully launched from their shipbuilding yard at Bill Quay, Newcastle-on-Tyne, a handsome new steel screw-steamer which they have built to the order of Messrs. Dent & Co., Quayside, Newcastle-on-Tyne. The vessel is a very fine specimen of a modern cargo boat, of the improved single-deck type, with poop, long bridge, and topgallant forecastle, and is of the following dimensions, viz.:—Length over all, 338 ft.; breadth, 48 ft.; depth, moulded, 24 ft. She is constructed to carry 5,100 tons deadweight, on about 20 ft. 6 in. draught of water, and has been built under special survey of Lloyd's for their 100 A1 classification, and has also been superintended during construction by Mr. J. Baxter, of Newcastle, the owners' surveyor. The vessel is rigged as a fore-and-aft schooner, with fidded topmasts, and is fitted with all the most modern description of deck machinery and other appliances for the efficient working of the vessel generally, and for facilitating the rapid loading and discharging of cargo. The saloon, captain's accommodation, and spare berths are in a large house on the bridge deck amidships; the chartroom is on flying bridge above; the officers' accommodation being in side houses, while the crew are berthed in the topgallant forecastle. The vessel is provided with water ballast in the cellular double bottom, all fore and aft. She will be fitted with a set of triple-expansion engines of the improved type, having cylinders 23½ in., 39 in., and 64 in. diameter respectively, with a stroke of 42 in., steam being supplied by two large steel multitubular boilers, working at 160 lbs. pressure per square inch. The machinery has been constructed and will be fitted by the North-Eastern Marine Engineering Co., Limited, at the Northumberland Engine Works, Wallsend-on-Tyne. The ceremony of christening the vessel was gracefully performed by Miss Cissy Dent, of Newcastle, who named the steamer *Crewe*.

Wellington.—On May 9th there was launched from Mr. Joseph Scarr's shipyard at Grovehill, Beverley, a steel screw-tug of the following dimensions:—Length over all, 69 ft.; beam, moulded, 16 ft. 5 in.; depth amidships, 9 ft. 4 in. She was built to the order of Mr. J. Constant, of London, and is the third tug built for the same owner. The vessel has been built to class A1 Lloyd's. As the vessel left the ways she was christened *Wellington* by Miss Gertrude Scarr, daughter of the builder.

Isernia.—On May 10th there was launched at Hull, for the Great Grimsby and East Coast Steam Fishing Co., Limited, of Grimsby, an iron steam ketch, named the *Isernia*.

Ohio.—On May 10th there was launched by Messrs. Bartram and Sons, at Sunderland, a steamer of the spar-deck type, built for the Neptune Steam Navigation Co., Limited, for whom Messrs. W. & T. W. Pinkney, Sunderland, are the managers. The vessel has been especially designed to suit the American trade, and has passenger accommodation of first-class order. Her dimensions are:—Length, 410 ft.; breadth, 46 ft. 6 in.; and depth, 29 ft. 6 in. The propelling machinery will be provided by Messrs. George Clark, Limited, the cylinders being 25½ in., 43 in., and 73 in. by 48 in. She is constructed to carry 6,000 tons of cargo, and is expected to accomplish 12 knots an hour loaded. The vessel, which was christened the *Ohio*, has been built to replace a former liner of the same name, and is the largest vessel now owned by the firm.

Saxon Prince.—On May 10th Messrs. Short Brothers launched from their shipbuilding yard at Pallion a finely modelled steamer of about 6,000 tons capacity, which they have built for the Prince Line, Limited, of Newcastle-on-Tyne, and which is the first of a description of steamers they are building for the West Indian Line. This steamer, which is built of steel, has been constructed under special survey to the highest class in Lloyd's register, and is of the following dimensions:—Length over all, 363 ft.; breadth, 45 ft.; and depth, moulded, 27 ft. 9 in. The vessel is divided by six watertight bulkheads, forming four large cargo holds, for working which there are six powerful steam winches with large donkey boiler. The double bottom is constructed for water ballast throughout, divided into trimming tanks. There is a short full poop, bridge house amidships, over top of which are large houses for the accommodation of captain, officers, and engineers, and a few passengers—the saloon being large and commodious, and fitted up in polished hardwoods, tastefully arranged, and lighted by electricity. On top of midship cabin-house are the wheel-house and chart-house and flying bridge. The steering gear is fitted in the engine-room with controlling rods to wheel-house. The crew are berthed in the topgallant forecastle. On leaving the ways the vessel was named *Saxon Prince*, the ceremony being gracefully performed by Miss Nora Donald, daughter of the vice-chairman of the company. The vessel is to be fitted by Messrs. Thomas Richardson & Sons, Limited, of Hartlepool, with engines having cylinders 24 in., 39 in., and 66 in., with a stroke of 45 in., steam being supplied by two large steel boilers working at 180 lbs. pressure.

Toxteth.—On May 10th there was launched at Liverpool, by Messrs. John Jones & Sons, the *Toxteth*, sister ship of the *Nelson*, recently delivered by the builders to the Alexandra Towing Co., Limited.

Brinkburn.—On May 11th there was launched at Whitby, by Messrs. T. Turnbull & Son, a large steel screw-steamer, to the order of Messrs. Harris & Dixon, of London. The dimensions of the vessel are as follows:—Length over all, 361 ft. 3 in.; length between perpendiculars, 350 ft.; breadth, extreme, 43 ft.; depth to top of ordinary floor, 28 ft. 6¼ in.; class, 100 A1, spar-deck, at Lloyd's. Messrs. Blair & Co. will supply direct-acting triple-expansion engines, having cylinders 24 in., 40 in., and 65 in., stroke 42 in.; two steel boilers, 160 lbs. working pressure. Deadweight carrying capacity, about 5,600 tons. The vessel was christened the *Brinkburn*, and is similar in dimensions to the *Hutton*, the last vessel built by the firm.

Inchkeith.—On May 11th Messrs. William Gray & Co., Limited, launched from their Central Shipyard the handsome steel screw-steamer *Inchkeith*, of the following dimensions, viz.:—Length between perpendiculars, 348 ft.; breadth, 47 ft.; depth 28 ft. 1½ in.; and deadweight capacity 5,600 tons on 22 ft. 5 in. draught. The vessel is an enlargement on the s.s. *Inchmona*, which was launched from the same yard three years ago, and which has marked an epoch in steamship efficiency. She is of an improved spar deck type with large measurement capacity, having poop, long bridge, and topgallant forecastle, with all the cabin, officers', and engineers' accommodation on the bridge. She is fitted with a double bottom forward, and a deep cargo tank aft, and has a total water ballast capacity of 1,287 tons. The machinery, from the Central Marine Works, of W. Gray and Co., Limited, consists of a set of Mudd's patent five-crank engines, working in quadruple expansion, supplied by steam at a working pressure of 260 lbs. per square inch, from two ordinary marine type boilers fitted with induced draught. The engines will develop more power than those of the *Inchmona*, which have given highly satisfactory results, and have fully justified the owners and builders in making such a large departure from the beaten track in the design of marine engines. Messrs. Hamilton, Fraser & Co., of Liverpool, the owners of the vessel, are to be congratulated upon the success of their enterprise in having the *Inchmona* built, and from the experience gained with her and the improvements made in the new ship and her machinery, even better results are assured to them in the s.s. *Inchkeith*. The steamer will take Lloyd's highest class, and has been constructed under the superintendence of Mr. J. B. Edmiston, assisted by Captain F. G. Major and Mr. T. S. Mossman. The ceremony of naming the vessel *Inchkeith* was gracefully performed by Miss Dorothy Cresswell Gray, Staincliffe, Seaton Carew.

Shandon.—On May 11th Messrs. Richardson, Duck & Co. launched from their yard a steel screw-steamer of the following dimensions:—Length over all, 352 ft.; breadth, extreme, 48 ft.; depth, moulded, 28 ft. 4 in.; tonnage, gross, about 3,860 tons, with a carrying capacity of about 6,500 tons. This steamer, which has been built to the order of Mr. W. J. Tatem, of Cardiff, will class 100 A1 in Lloyd's register, and has been built under special survey. She is the largest steamer yet built for Cardiff. The vessel is of the three-deck type with one laid deck; having cargo poop, long extended bridge with houses for captain, officers, and engineers' accommodation on bridge deck, and topgallant forecastle for crew. A cellular double bottom, and fore and aft peak tanks are fitted for water ballast; and the equipment includes six steam winches, large horizontal donkey-boiler, stockless anchors, steam windlass, steam-steering gear, &c. The engines, by Messrs. Blair & Co., Limited, have cylinders 25 in., 42 in., and 68 in. by 45 in. stroke, steam being supplied by two single-ended boilers having a working pressure of 160 lbs. As the vessel left the ways she was christened the *Shandon* by Mrs. Tatem, of Cardiff.

Celtic.—On May 12th there was launched by Mr. James Miller, at St. Monan's, a first-class fishing boat, built to the order of Mr. James Mackay. The craft, which was named the *Celtic*, is 62 ft. in length, with a breadth of beam 21 ft. 6 in.

Otta.—On May 13th there was launched by Messrs. John Priestman & Co., at Southwick, Sunderland, a handsomely modelled screw-steamer, built to the order of Mr. Lauritz W. Hanson, of Bergen, Norway. Her dimensions are:—Length, 336 ft.; breadth, 47 ft.; depth, moulded, 26 ft. 10 in. The vessel has been constructed to "Der Norske Veritas" and Lloyd's highest class, three-deck rule. A full poop is fitted aft, long bridge amidships, and topgallant forecastle. The hold is divided into watertight compartments by five steel bulkheads, and a double-bottom forward and aft divided into four separate tanks, together with the after-peak, provide ample water ballast. The engines are of the triple-expansion type, and have been built by Messrs. Wm. Allan & Co., Limited, and have cylinders of 25 in., 41 in., and 67 in. by 45 in. stroke. The boilers supply steam at a pressure of 160 lbs. per square inch. Mrs. Anderson, of South Shields, named the vessel *Otta*.

Stat.—Lately there was launched from the yard of Wm. Harkess & Son, Middlesbrough-on-Tees, a steel screw-steamer, 160 ft. by 25 ft. by 13 ft., built to the order of a Norwegian firm for their fishing trade on the coast of Norway. She will be fitted with triple-expansion engines by Sir C. Furness, Westgarth & Co., Limited, and be classed 100 A1. Lloyd's. She was named *Stat*.

LAUNCHES.—Scotch.

Balmoral Castle.—On April 8th there was launched from the yard lately occupied by Messrs. Donaldson, Aitken & Scott, Govan, the iron screw-trawler *Balmoral Castle*, built for Mr. J. A. Smith, fish merchant, Hull. The vessel, along with others, was contracted for by the firm mentioned, and the work is now being finished by Messrs. Cochrane & Cooper, of Beverley, on behalf of the owner. The vessel is 115 ft. in length, 21 ft. broad, and 11 ft. 3 in. deep. She will be registered 100 A1 at Lloyd's, and will have triple-expansion engines by Messrs. Anderson & Co., Pollokshaws.

Irishman.—On April 22nd the Irvine Shipbuilding and Engineering Co., Limited, Irvine, launched a steel screw-steamer of 250 tons deadweight, to the order of Messrs. John Kennedy & Sons, Glasgow. The vessel has been built for the owners' coasting trade, her dimensions being 120 ft. by 21 ft. 6 in. by 9 ft. 6 in. Messrs. Muir & Houston, Limited, Glasgow, are supplying machinery of the c.s.c. type, having cylinders 16 in. and 32 in. by 22-in. stroke, with a large steel boiler working at 130 lbs. pressure. The vessel was named *Irishman*.

San Salvador.—On April 24th there was launched at Port-Glasgow a steel schooner-rigged steamer, of about 1,860 tons gross, named the *San Salvador*.

Steel Screw Steamer.—On April 24th Messrs Russell & Co., Port-Glasgow, launched a steel screw-steamer of the partial awning-deck type to their own account. The dimensions are:—Length, 237 ft.; breadth, 34 ft. 6 in.; depth, 17 ft. 6 in. This steamer has been built to Lloyd's highest class, and is specially constructed for the Baltic and light-draught trade. Messrs. Kincaid & Co., Greenock, will supply the machinery, the cylinders being 17½ in., 28½ in., and 46½ in. by 33 in. stroke.

Equator, Erne, and Emulator.—On April 24th Messrs. Mackie & Thomson launched from their yard at Govan the *Equator*, *Erne*, and *Emulator*, steam trawlers, of 160 tons each, for the Great Northern Steamship Fishing Co., Hull. The vessels will be fitted with triple-expansion engines by Messrs. Muir & Houston, Kinning Park, Glasgow.

Lakonia.—On April 24th the London and Glasgow Engineering and Shipbuilding Co., Limited, launched at Govan a large steel screw-steamer for Messrs. Donaldson Brothers' Canadian cattle and cargo trade. This is the second steamer the firm has built for Messrs. Donaldson Brothers within the last two years. The dimensions of the vessel are:—401 ft. 9 in. by 49 ft. by 31 ft. moulded, with poop, bridge, upper bridge, and topgallant forecastle; she is classed 100 A1 three-deck rule at Lloyd's, and has Board of Trade passenger certificate. She is designed to carry over 7,000 tons deadweight, with a gross tonnage of about 4,700 tons, and is fitted with all the most modern appliances for handling cargo, &c., including 10 powerful steam winches. The upper deck throughout is fitted for cattle, and the main deck is arranged so that it also can be used for cattle. The steam winches are placed on platforms raised sufficiently high above the upper deck to keep them clear of the cattle. The after 'tween decks are divided into four refrigerating chambers for the carriage of Canadian dairy produce, frozen meat, &c. Besides having a double bottom on the cellular system, all fore and aft, there is a large chamber tank abaft the engine-room holding about 700 tons, and the fore and aft peaks are also fitted for water ballast. The captain, officers, and engineers are berthed on the bridge deck, also the saloon and passengers' accommodation. A new feature in this steamer is that all the crew, firemen, and cattlemen are berthed on the after part of bridge deck in sidehouses, which, besides being more comfortable quarters for the men, enables all the space on upper deck to be utilised for cattle, there being space for nearly 500 on this deck alone. Another special feature of the vessel is the ventilation, numerous cowls being distributed throughout the ship to thoroughly ventilate the holds and 'tween decks, and there is also a steam fan fitted for circulating the air in the 'tween decks, and everything has been arranged for passing the American and British regulations for carrying cattle and grain, including shifting boards, &c. The propelling machinery, which is supplied by the builders, consists of one set of triple-expansion engines having cylinders 28 in., 47 in., 76 in. diameter by 54 in. stroke. Steam is supplied by three single-ended boilers constructed for a working pressure of 170 lbs., and fitted with Howden's system of forced draught. A large auxiliary boiler is also fitted for supplying steam to winches, &c. As the vessel left the ways she was gracefully named *Lakonia* by Mrs. M'Leod, of Glasgow.

City of Aberdeen.—On April 26th there was launched at Aberdeen, for Captain Spence, of Aberdeen, a steel steam ketch, of about 162 tons gross, named the *City of Aberdeen*.

Amazonense.—On April 27th Messrs. David J. Dunlop & Co., engineers and shipbuilders, Inch Works, Port-Glasgow, launched from their yard at high water the above-named steel screw-steamer, of which the following are the principal particulars:—Length, from fore part of stem to aft part of post, 312 ft.; breadth, moulded, 40 ft. 9 in.; depth, moulded, to spar deck, 26 ft.; gross tonnage, about 2,500 tons. The vessel has been built under Lloyd's special survey to obtain their highest class as a "spar deck" steamer, and is to the order of Messrs. R. Singlehurst & Co., of Liverpool, for their well-known trade, her construction having been carefully supervised on behalf of the owners by Messrs. George Hepburn & Son, Liverpool, and Mr. Isaacs, owners' marine superintendent. The erections over the spar deck consist of a full poop, bridge, and topgallant forecastle; and over the bridge deck upper erections are fitted at forward and after ends, extending the full width of vessel, the former having a large steel deckhouse containing saloon finished in solid polished oak framing, with all the latest commodities and staterooms, bathrooms, pantries, lavatories, &c., for accommodation of first-class passengers. On top of this deckhouse is fitted a large teak house, in which commodious rooms are fitted for captain, and charthouse, over which again the flying bridge is built. The erections over after part of bridge deck, as well as the poop deck, have been adapted for locating the boats and life-saving appliances. Ample provision has been made for the accommodation of the engineers and officers, as well as the crew; and the outfit of the steamer includes Hall's patent stockless anchors for stowing in the hawse pipes, Emerson & Walker's steam windlass, warping capstan aft, and five steam winches by Dunlop, Bell & Co., 10 cargo derricks, and special portable derrick, and all gear for same, capable of handling 35 tons, at fore and main masts. The steering gear is a special feature in the vessel's fittings, this being furnished by Messrs. Fawcett, Preston & Co., of Liverpool, and of Oglethorpe's hydraulic type, with Hastie's screw gear on poop, Wailes, Dove & Co.'s patent bitumastic solution in bunkers and peaks, Bruce's outfit of compasses and nautical instruments, complete installation of electric light by Holmes, of Newcastle; in fact, all the most modern and approved appliances for the safe and speedy working of the vessel have been adopted. After the launch the vessel was moored alongside the builders' wharf to receive her machinery, &c., which consists of one set of triple-expansion engines, having cylinders 22½ in., 37 in., and 60 in. diameter, and 45 in. length of stroke, the steam for which is supplied by one large single-ended boiler 16 ft. 3 in. diameter by 11 ft. 6 in. long, all proportioned for a working pressure of 180 lbs. per square inch. The boiler is fitted with forced draught on Howden's latest principle. Boiler feed pumps are supplied by G. & J. Weir, Limited, while the evaporator, feed heater, feed water filter, and ballast pumps are all supplied by the Liverpool Engineering Co. In addition, a large marine type donkey-boiler is fitted to provide steam for deck machinery. The launch was witnessed by a large company of ladies and gentlemen. Amongst those present were Mr. Isaacs, Mr. George Hepburn, and Captain Hughes, representing the owners, and Mr. Dunlop the builders. The naming ceremony was most gracefully performed by Mrs. William Isaacs. The new steamer will be commanded by Captain Hughes, who has had long experience in the service of the owners.

Alabama.—On April 28th Messrs. Charles Connell & Co. launched at Whiteinch the steel screw-steamer *Alabama*, which they have built to the order of Messrs. Robert MacKill & Co., for the United Steamship Co., of Copenhagen. The dimensions of the vessel are:—Length, 375 ft.; breadth, 50 ft.; depth, 28 ft. 6 in., moulded, with a deadweight capacity of about 7,000 tons. She has been built to Lloyd's highest class, with a cellular double bottom right fore-and-aft for water ballast, and is fitted with all the latest appliances for the rapid and efficient working of ship and cargo. The engines, constructed by Messrs. David Rowan & Co., of Glasgow, are of the triple-expansion type, having cylinders 25 in., 41 in., and 67 in. by 48 in. stroke, with two single-ended boilers.

Saldanha da Gama.—On April 28th there was launched from Panmure Shipyard, Dundee, a screw-steamer for Brazilian owners, and intended for the cattle-carrying trade on the Amazon. She has been named *Saldanha da Gama*, and is 170 ft. long, 26 ft. 6 in. broad, and 12 ft. 6 in. deep, with a gross tonnage of 600 tons.

Cragoswald.—On April 29th Messrs. William Hamilton & Co. launched from their Glen Yard, Port-Glasgow, a steel screw-steamer, for Messrs. Lunn & Maccoy, Newcastle-on-Tyne, for the general and Eastern trade. The dimensions of the vessel are:—Length between perpendiculars, 330 ft.; breadth, 45 ft. 6 in.; depth, moulded, 26 ft. 6 in., with poop, bridge, upper bridge, and topgallant forecastle; and she is classed at Lloyd's 100 A1. She is designed to carry over 5,400 tons deadweight on a comparatively light draught of water, with a net registered tonnage under 2,100, and a gross tonnage of 3,400. The propelling machinery, which is being supplied by Messrs. David Rowan & Co., of Glasgow, consists of one set of triple-expansion engines, having cylinders 24 in., 40 in., and 66 in. diameter respectively, by 42 in. stroke. Steam is supplied by two large boilers constructed for a working pressure of 180 lbs. As the vessel left the ways she was named the *Cragoswald* by Miss Hettie Maccoy, of Newcastle.

Guatemala.—On April 29th Messrs. Caird & Co., shipbuilders, launched at Greenock the steel twin-screw steamer *Guatemala* for the Pacific Steam Navigation Co. The vessel, which is of 3,500 tons gross, is of the following dimensions:—359 ft. in length, 43 ft. broad, and 22 ft. 6 in. deep, and will be engined by the builders.

Tantallon Castle.—On May 6th there was launched by Messrs. John Scott & Co. at Abden Works, Kinghorn, the first of the two paddle steamers for the Galloway Saloon Steam Packet Co. The vessel is designed and constructed to obtain a No. 3 Board of Trade certificate (passenger), which enables her to sail between Leith and Dundee, or on to Berwick and Newcastle. Her dimensions are:—210 ft. long between perpendiculars by 25 ft. beam, and 55 ft. wide over sponsons, by 8 ft. 6 in. depth, moulded, to main deck and 16 ft. 6 in. to promenade deck. The promenade deck extends 145 ft. fore and aft by the full width of the vessel. Every part of this deck is available for passengers except the portion taken up with the two funnels and ticket office. There are no openings from end to end on this deck, the sponsons having been taken advantage of to contain the stairs (four in number) leading between the main and the promenade deck. The portion of the main deck abaft the machinery has been taken up with the first-class main saloon, which extends the full width of the vessel. The smoke-room is forward of engine and boiler space. Attention has been given to the dining accommodation, the first-class under the main saloon, and the second-class under smoke-room, each fitted with a large bar and pantry. Alongside of the engine and boiler casing on either side, and extending from front of main saloon to front of smoke-room, are covered-in alleways, which will prove a great boon to passengers in case of stormy weather, and will be sure to be taken advantage of. The main engines are of the diagonal compound surface-condensing of 1,800 I.H.P.; the boilers work under forced draught on the close-stokehole principle, and designed to propel the vessel at a mean speed of 17 knots. As the vessel left the ways for her native element she was gracefully christened the *Tantallon Castle* by Mrs. Aitken, wife of the chairman, and, as is usual with vessels built by John Scott & Co., she immediately steamed off on her preliminary trial trip.

Calchas.—On May 8th Messrs. Scott & Co. launched at Greenock the screw-steamer *Calchas*, for the Ocean Steamship Co., Liverpool. Dimensions:—Length, 441 ft.; breadth, 52 ft. 6 in.; depth, 30 ft. 3 in.: of 6,763 tons gross, with a carrying capacity of 8,200 tons. The builders will supply triple-expansion engines of 4,200 I.H.P.

Paris.—On May 9th the Irvine Shipbuilding and Engineering Co., Limited, launched from their yard at Irvine a steel screw-steamer of about 750 tons deadweight, to the order of Messrs. B. P. Hutchison, Glasgow. The vessel has been built to Lloyd's 100 A1 class under special survey, and has been specially designed to meet the requirements of the owners, Continental trade, her dimensions being 180 ft. between perpendiculars by 27 ft. 6 in., by 14 ft. moulded; water ballast is fitted in holds, and fore-and-after peak tanks, and the vessel is supplied with steam-steering gear, direct-acting steam windlass and capstan combined, and powerful deck machinery for the speedy handling of cargo. This vessel is a duplicate in design of the s.s. *Hector* built last year by the same firm for Messrs. Hutchison. The machinery and boilers are being supplied by Messrs. Hutson & Son, Limited, Kelvinhaugh, Glasgow. The vessel on leaving the ways was gracefully named *Paris* by Mrs. Gaff, Woodstow, Maxwell Park, Glasgow.

Bavarian.—On May 11th Messrs. William Denny & Brothers launched at Dumbarton a twin-screw steamer of 10,200 tons, for Messrs. James & A. Allan, of Glasgow. The vessel, which is by far the largest in the company's fleet, is 520 feet long over all, 59 ft. in beam, and 43 ft. deep. She has been designed to meet the latest requirements of the Allan Line's Canadian trade. The hull is built of steel to the requirements of the Board of Trade for foreign-going passenger steamers, and the construction and design have been under the special survey, and with the scantlings required by the British Corporation for their highest class. When completed, the vessel will have accommodation for about 162 first-class passengers in the fore-end of the bridge, and on the bridge deck, 136 second-class in after-part of bridge and on upper deck amidships, and 200 third class in upper deck aft. The engines and boilers are being supplied by Messrs. Denny & Co., and consists of two sets of triple-expansion engines, and a set of single-ended boilers. The vessel was named *Bavarian* by Mrs. Bryce Allan.

Taymouth.—On May 12th Messrs. Gourlay Brothers launched at Dundee the first of two steam trawlers which they have built for the Tay Trawling Co. The vessel, which is built to the highest class at Lloyd's, under special survey, is 105 ft. long, 20 ft. broad, 11 ft. deep, and her gross tonnage is 135 tons. The machinery consists of a set of triple-expansion engines and one large single-ended boiler. The vessel was christened *Taymouth* by Mrs. Robert Cook, wife of the managing director of the company.

Pervi.—On May 12th Messrs. Wm. Simons & Co., Limited, launched complete from their works at Renfrew the first of two powerful dredging vessels, which they have constructed to undertake extensive dredging operations in connection with the improvement of Port Arthur and Tallenwan. The vessel has been built under the direction of Mr. Totshyski, inspecting engineer, assisted by Mr. Johnson. The dredger, in addition to being provided with a chain of buckets for discharging into barges alongside, is fitted with a sand suction pump, also with a mud discharging pump; to which is attached fully 2,000 ft. of shore discharging pipes, carried on floating pontoons, having flexible joints. The vessel is capable of dredging and discharging 1,000 tons of spoil per hour, and of working to a depth of 40 ft. below the water level. Two pair of compound surface-condensing engines are fitted for propelling the vessel at a speed of seven knots per hour. It is constructed in accordance with the rules of Bureau Veritas for the highest class for a vessel of this type. Electric light installation is provided for working day and night. A repairing room is also fitted on board with turning lathe, drilling and planing machine, &c. As the vessel left the ways she was named *Pervi* by Mrs. Walter Brown, Monkdyke, Renfrew.

Kinfauns Castle.—On May 12th the Fairfield Shipbuilding and Engineering Co., Limited, Govan, Glasgow, launched the *Kinfauns Castle*. The vessel is built with a straight stem and elliptical stern, a very long forecastle, and a promenade deck and poop extending about four-fifths of the length of the vessel. Under the promenade deck is a central house 9 ft. high, leaving a passage at the ship's side. Eight ft. 6 in. above the promenade deck is a boat deck with deck-house, and on this deck provision is made for carrying the lifeboats. The vessel is built of steel throughout to the requirements of the Board of Trade for a foreign-going passenger steamer, also under special survey, and with scantlings, as required by Lloyd's latest rules for the 100 A1 class. A cellular double-bottom is fitted the full length of the ship, and the holds are subdivided into separate compartments by watertight bulkheads, which are arranged and constructed so as to meet the recommendations of the Bulkhead Committee, with a double collision bulkhead fitted forward. All the decks are plated and sheathed with teak. The *Kinfauns Castle* will have two large funnels, each 110 ft. long, and 15 ft. by 11 ft. diameter, and three raking-pole masts, fore-and-aft schooner-rigged. Her dimensions are as follows:—Length, over all, 532 ft. 3 in.; length on water line, 515 ft.; breadth, extreme, 59 ft. 3 in.; depth, moulded, 38 ft. 9 in. The gross tonnage is about 9,700 and the I.H.P. about 10,000. When completed the vessel will contain accommodation for about 300 first-class passengers, berthed amidships; 160 second-class, berthed aft; and about 200 third-class, berthed forward. The sanitary accommodation and lavatories throughout the vessel have received special consideration, and are of the latest and most approved description. The ventilation has been carefully studied, and a most complete system adopted. Electricity is brought to bear in ventilating the saloons, corridors, and sleeping cabins in between decks, by means of a large number of electric fans. A continuous water service will be supplied throughout the ship. A complete installation of electric light is being arranged on board, the generating plant consisting of three independent sets of engines and dynamos. Electric bells will be fitted to the sleeping cabins and saloons. A large refrigerating plant is also to be fitted on board, and specially insulated chambers will be provided for the supply of meat, fish, poultry, vegetables, milk, fruit, &c. The cargo hatches will be equipped with 9 steam winches for the rapid handling of cargo, an additional steam winch being also fitted for the purpose of hoisting the boats, of which sixteen are provided, in addition to a full outfit of life-saving appliances and all other details required by the Board of Trade Passengers Act. The steam steering engine is placed aft on the poop deck, enclosed in a house and controlled from the navigating bridge, also the reserve hand gear and steering wheels. A large steam windlass with frictional brakes and capstan will be fitted on the forecastle deck, adapted for the cables, which are 2⅞ in. in diameter. There are four heavy anchors made of nickel steel and of Hall's patent stockless pattern. Two powerful steam-warping capstans with separate engines are placed on the poop deck. Some idea of the dimensions of the ship may be gathered from the fact that a walk half-a-dozen times round the promenade deck means about a mile.

In order to minimise rolling, deep plate bilge keels are fitted, and these with the centre bar keel—having together a side area of 750 square feet—will ensure greater comfort for passengers by reducing very considerably the angle of roll in bad weather.

The propelling machinery consists of two sets of four-cylinder, four-crank quadruple-expansion engines, balanced on the Yarrow-Schlick-Tweedy system.

This type of machinery, with a boiler pressure of 210 lbs. per square inch, ensures great economy of fuel, combined with minimum vibration of the ship. The engines are designed to run at a high piston speed, with large bearing surfaces, and comparatively light reciprocating parts. The shafting is of Whitworth steel throughout, and the working parts are forged from ingot steel, the principal bolts being specially annealed. The main condensers of galvanised steel plate are elliptical in section. They are placed close to the ship's side, and do not form part of the framing of the engines. In this and several other respects the machinery compares favourably, as regards weight, with the type of engine usually fitted in mail steamers. The pistons are of Whitworth steel, and, to carry out the balancing of the engines as accurately as possible, they were turned down to the correct weight after the other reciprocating parts were finished and weighed. The propellers are of bronze with cast steel bosses. Every care has been taken to combine with the highest class of material and workmanship all details which experience has proved to be necessary to obtain freedom from breakdown on a long ocean run. Two powerful independent centrifugal pumping engines are fitted in the engine room, and are so arranged that both main condensers can be circulated by either pump in the event of a breakdown of the other. Each of these pumps has a special bilge suction connection, so that, in the event of a serious leak above the double bottom, both can be used for pumping out the ship. The discharges from these and all other pumps are below the water line, to avoid spray being carried into the stateroom side ports. Three large steam pumps are fitted specially for hot bath, cold bath, sanitary, and fire service purposes. The fire service mains from these pumps are carried right fore and aft on the weather deck, and also in the passenger 'tween decks, with connections for hose at the necessary points. Very special plant is provided, entirely in duplicate, for evaporation and distillation. The total output of pure cool drinking water from this installation is 13,000 gallons per day. Combined with the fresh-water supply throughout the ship there is a complete installation of filters of the Berkfeld type, which ensure absolute immunity not only from ordinary impurities held in suspension, but from disease organisms being carried by the water.

For the refrigeration of ship's provisions and the carrying of fruit or other cargo, a powerful duplex CO_2 machine is fitted in combination with six large insulated cold chambers. There are also larders, wine and mineral water coolers in every bar, and cooled water drinking fountains throughout the ship.

The electric light and power installation is on a considerable scale. In addition to nearly 1,000 lights in the ship, there are 26 motor-driven blowing and exhausting fans (20 of which are each capable of passing 3,400 cubic feet of air per minute) for sending air down to the engine-room and stokeholds, and for extracting vitiated air from the passenger 'tween decks. Electric lifts are employed for hoisting ashes in port when the hydro-pneumatic ejectors are not in use. Motors are also freely used throughout the ship for working roasting ovens, for knife cleaning, coffee grinding, hair brushing, &c. For signalling in fog an electrically controlled steam whistle is fitted, which is automatically sounded at the required intervals of time by a clock control. For communicating between the navigating bridge and the engine-room, and other parts of the ship, loud-speaking telephones are fitted. The attendance at the launch was exceptionally large. Lady Georgina Home-Drummond performed the launching ceremony.

Barrow Castle.—On May 13th the Ailsa Shipbuilding Co., Troon, launched from their yard a steel screw-steamer, which they have built for Messrs. Robert M'Cowen & Sons, Tralee, for-the general coasting trade. The dimensions are:—Length between perpendiculars, 145 ft.; breadth, moulded, 23 ft. 6 in.; depth, moulded, 11 ft.; and carrying capacity 400 tons. Compound engines with cylinders 18 in. and 38 in. by 27 in., are being supplied by Messrs. Dunsmuir & Jackson, Govan. The naming ceremony was performed by Mrs. Jackson, who named the vessel *Barrow Castle*.

Venture.—On May 15th the Caledon Shipbuilding and Engineering Co., Limited, Dundee, launched a steel twin-screw steamer to be employed in the oil trade on the Caspian Sea. Her dimensions are:—Length, 255 ft.; breadth, 32 ft.; depth, 18 ft.; carrying capacity, 1,500 tons. The vessel has been built to the order of Sir Christopher Furness, London and West Hartlepool, for Messrs. Alfred Stuart & Co., London, and has been named *Venture*.

Dundalk.—On May 16th there was launched by Messrs. A. & J. Inglis, at Pointhouse, on the Clyde, a twin-screw steamer for the Dundalk and Newry Steam Packet Co.'s Liverpool service. The vessel was named the *Dundalk* by Mrs. Brown, daughter of the chairman of the company.

Silvio.—On May 20th there was launched from the yard of the Campbeltown Shipbuilding Co. the second of two steel screw-steamers, built to the order of the Bristol Steam Navigation Co. The vessel, which is of 2,000 tons deadweight, and has been built to the highest class at Lloyd's, is intended for Continental trading. She will be engined on the Clyde. On leaving the ways the steamer was gracefully named *Silvio* by Mrs. Peter Mackay.

Duchess of Fife.—Lately there was launched from the works of the Clydebank Engineering & Shipbuilding Co., Clydebank, the paddle steamer *Duchess of Fife*, designed for the joint service of the London & South-Weston and London, Brighton & South Coast Railway Co.'s between Southampton and the Isle of Wight. The vessel is 215 ft. long, 26 ft. broad, and 10 ft. deep. The propelling machinery is of the compound-diagonal direct-acting type, with two cylindrical boilers, working at a steam pressure of 150 lb. per square inch. All the auxiliary machinery is of exceptional power, and of the most modern type. The launching ceremony was performed by Miss Brown, daughter of Mr. R. Brown, the marine superintendent of the joint companies at Portsmouth. The vessel will be placed on the summer excursion service immediately on delivery. She has been built to comply with Board of Trade requirements as regards hull, machinery and equipment.

Elba.—On May 24th Messrs. Ramage & Ferguson, Limited, Leith, launched a steel screw-steamer, built to the order of Messrs. James Currie & Co., Leith, for their general cargo trade. The principal dimensions of this vessel are:—Length, 225 ft. by 33 ft. 3 in. beam, by 16 ft. 11½ in. depth, moulded; and the engines are triple-expansion, with cylinders 18½ in., 30 in., and 49 in. diameter, by 33 in. stroke, steam being supplied from a large single-ended boiler, working up to 165 lbs. pressure. The steamer has been built to the highest class at Lloyd's and has all the most modern improvements for working cargo. On leaving the ways, the vessel was named *Elba* by Mrs. Crawford, 21, Stirling Road, Trinity; and subsequently the builders entertained a company to lunch, including Mr. James Currie, Mr. James Currie, jun., Mr. A. Currie, Mr. Crawford, and others, when the toasts usual on such occasions were duly proposed and honoured. This is the twelfth steamer launched by the same firm for Messrs. James Currie & Co.

LAUNCHES.—German.

Saxonia.—On April 19th there was launched by the Flensburg Shipbuilding Co. the s.s. *Saxonia*, a steel screw steamer of about 6,000 tons, built to the order of the Hamburg American Line. The vessel, which is constructed to German Lloyd's class 100 A1, is 414 ft. 6 in. long, 46 ft. 5 in. broad by 30 ft. 2½ in. depth, moulded, with long poop and topgallant forecastle. A full equipment is fitted of the most efficient machinery for a rapid loading and discharging of all descriptions of cargo. She is intended for the trial Hamburg-East-India. The accommodation for officers is placed in a deckhouse on top of poop, amidships. Her engines, of 1,800 H.P., will also be built by the Flensburg Shipbuilding Co. As the vessel left the ways she was named *Saxonia* by Miss Erna Lempelius.

Steel Lighter.—On April 20th a new steel lighter left the Flensburg Shipyard. The dimensions are:—Length, 84 ft.; beam, 21 ft.; depth, moulded, 8 ft. 6 in. The vessel is built on the self-trimming system patent of Mr. Bredsdorff, managing director of the Flensburg Shipbuilding Co. The advantages of ships built according to this system are that they take a full cargo of coals and grain without any trimming, and that it is impossible for the cargo to shift, which is of the greatest importance. The lighters are intended for trade between the new free port of Copenhagen and all Baltic ports. There are five other barges on this system under construction for the same company, Det Danske Damper og Lægter Co.

TRIAL TRIPS.

Seapoint.—On April 22nd the s.s. *Seapoint* proceeded down the Clyde for her trial trip. The *Seapoint* is a fine screw steamer of the raised quarter-deck type and constructed with the most recent improvements necessary for the modern coasting trade. She has been built by the well-known firm of S. McKnight & Co., Limited, of Ayr, for Messrs. Joseph Fisher & Sons, of Newry. The dimensions of the vessel are:—175 ft. by 26 ft. 6 in. by 13 ft. moulded, and she is capable of carrying considerably over 700 tons deadweight on a very small register, while at the same time her capacity is such as to enable the deadweight to be stowed at the rate of nearly 50 cubic feet to the ton. The *Seapoint* has been constructed to the highest class at Lloyd's under special survey. She has cellular double bottom for water ballast throughout the whole length of the hold, and her bottom generally is specially strong for loading aground. Powerful steam-steering gear is fitted on the bridge amidships, also powerful steam winches for the quick handling of cargo. She has a large rudder, and a special feature of the trial was the facility with which she was steered, this being a necessity for the owners' trade when passing up canals. On the measured mile at Skelmorlie six runs were taken, and a mean speed of 9·794 knots was attained, the vessel at the time being fully loaded and in seagoing trim. The machinery has been supplied by Messrs. McKie & Baxter, engineers, Govan, and has also been constructed under Lloyd's rules for the highest class. It consists of a set of compound surface condensing engines, cylinders 19 in. and 44 in. by 30 in. stroke, supplied with steam from an extra large horizontal return tube marine type boiler. The workmanship is of the highest class throughout and during the trial the machinery worked exceedingly satisfactorily. After completion of the speed &c., trials, the vessel proceeded on her maiden voyage to Newry.

Montfort.—On April 26th the s.s. *Montfort* built by Palmers Shipbuilding & Iron Co., Limited, to the order of Messrs. Elder, Dempster & Co., of Liverpool (of which we gave full particulars in our Launch columns, March issue, page 514), was taken to sea for her official steam trials; during which the engines worked in a highly satisfactory manner at 79 revolutions per minute, and a mean speed of 12·389 knots was attained on the measured mile.

Secunda.—On Wednesday, April 26th, the Flensburg Shipbuilding Co. sent out for trial trip the new steamer *Secunda*, which they have built for the Flensburger Dampfschifffahrts-Gesellschaft von 1869 (of which we gave particulars in our Launch columns, April issue, page 44). Her engines of 200 H.P. gave the vessel an average speed of 10·8 knots. Two large boilers working at a pressure of 105 lbs. gives the steam. After the trial the steamer proceeded to Blyth, where she will load her first cargo.

Airedale.—On April 26th the fine steel screw-steamer *Airedale*, built by Messrs. Wm. Gray & Co., Limited, to the order of the London & Northern Steamship Co., Limited, London (Messrs. Pyman Brothers, managers), left West Hartlepool for her trial trip. The *Airedale* is a first-class cargo vessel, built to Lloyd's highest class, and is of the following dimensions:—Length over all, 341 ft.; breadth, 47 ft.; depth, 24 ft. 10 in. The engines are of the Central Marine Engine Works usual triple-expansion type, having cylinders 24 in., 38 in. and 64 in. in diameter, with 42 in. piston stroke, and two large steel boilers working at a pressure of 170 lbs. per square inch. The vessel and her machinery have been built under the superintendence of Mr. Wm. Birchby, and that gentleman, together with Captain Murrell, from the shipyard, and Mr. W. C. Borrowman, from the engine works, was present at the trial, which was in every way satisfactory, the average speed being 10½ knots. After the trial, the vessel proceeded to Barry Dock to load for the River Plate.

Newholm.—On April 29th the s.s. *Newholm*, which has been built to the order of Messrs. J. J. & C. M. Forster, of Newcastle, by C. S. Swan & Hunter, Limited (of which we gave full particulars in our Launch columns, April issue, page 42), was taken out to sea for her trial trip. Everything worked with perfect smoothness, and a mean speed of 11¾ knots was attained on the measured mile, which was considered highly satisfactory. During construction the vessel has been under the supervision of Captain Sarah, the marine superintendent of the owners' and the machinery under that of Mr. J. R. Scott, their superintendent engineer.

Ravenshoe.—On May 1st the steel screw-steamer *Ravenshoe*, the first vessel completed by the Northumberland Shipbuilding Co., Limited, of Howdon-on-Tyne (of which we gave full particulars in our Launch columns, March issue, page 514), was taken to sea for her trial trip. This vessel is of a type specially designed for the Cardiff trade, with a view to saving trimming dues, and has been built for the Seville and United Kingdom Carrying Co., Limited, Mr. John Cory being the managing director. On the measured mile a speed of 11 knots per hour was attained, the engines working in a satisfactory manner.

Java.—On May 3rd the s.s. *Java*, built by Messrs. Ropner & Son, of Stockton-on-Tees, left for her official trial trip in the Tees Bay. This steamer is built on the three-decked rule, with full poop, very long bridge, and top-gallant forecastle. The saloon and cabins for the captain and officers are fitted in the poop, and the engineers in iron houses on the bridge deck. The vessel will carry about 3,000 tons of cargo on Lloyd's summer freeboard, on a light draught of water, having cellular bottom of ample capacity for water ballast. She is fitted with all the most recent appliances for the expeditious and economical loading and unloading of cargoes, and her general outfit is fully up to date. The engines are supplied by the well-known firm of Messrs. Blair & Co., Limited, Stockton, of about 1,250 I.H.P. The trial trip was very satisfactory in every respect, and, after the adjustment of compasses, the steamer proceeded on her run round to Cardiff, where she will load. She is owned by the Societa Anonima Ungherese di Armamento Marittimo Oriente, of Fiume, Austria, who were fully represented at the trial by Mr. Cosulich and Mr. Nicolich, whilst the builders were represented by Mr. Leonard Ropner.

Akebono.—On May 4th, the torpedo-boat destroyer *Akebono* (*Dawn*), just completed for the Imperial Japanese Government by Messrs. Yarrow & Co., Limited, of Poplar, went through her official trials at the mouth of the Thames. The trial consisted of a three-hours' continuous run, carrying a load of 35 tons, when a speed was obtained of 31·159 knots. This is the third destroyer, having a speed of over 31 knots, which this firm has constructed for the Japanese Government; and these vessels constitute the fastest group of destroyers yet possessed by any nation. The Japanese Government were represented by Constructor-Commander Kondo, and Constructor-Captain Kurobe.

Anversville.—On May 5th the fine twin-screw mail and passenger steamer *Anversville* built by Sir Raylton Dixon & Co., Limited, Cleveland Dockyards, Middlesbrough, to the order of Messrs. Elder, Dempster & Co., of Liverpool, for the Compagnie Belge Maritime du Congo, of Antwerp, was taken out to sea for her official trials, under the command of Captain Acton Blake. This vessel will run in the Belgian Mail Line between Antwerp and the West Coast of Africa. Her dimensions are: Length, 383 ft.; beam, 46 ft.; depth, moulded, 25 ft. Exceptionally fine accommodation is provided for 108 first-class passengers in handsomely fitted state rooms, opening off a wide corridor amidships; which, being open to the front of poop, admits a current of air, which is so desirable in hot climates. The saloon is in a house on top of the bridge, so as to be well lighted and ventilated all round; the walls are panelled in marble, the tables arranged for seating small parties separately, and all very handsomely upholstered. The entrance lobby and ladies' lounge above are *en suite* with the saloon, and a spacious smoke-room is on top of shelter-deck. The second-class accommodation, for 70 passengers, is better than in most steamers, first-class, having spacious saloon, smoke-room, state-rooms and baths, well decorated and splendidly ventilated. The whole ship is lighted throughout with electric-light, and a powerful refrigerating machine, with large cooling chambers is, provided for the conveyance of fresh meat, provisions, &c. Twin-screw triple-expansion engines have been fitted by the Wallsend Slipway & Engineering Co., Limited, Newcastle-on-Tyne, having cylinders 21½ in., 35 in., 59 in. by 42 in. stroke, supplied with steam by four large boilers working at 180 lbs. pressure and fitted with Howden's system of forced draught. A small party of friends were on board during the trials, which passed off most successfully, a speed of 14 knots being easily attained.

Valetta.—On May 6th the screw steamer Valetta, built by Messrs. Murdoch and Murray, Port Glasgow, and engined by Messrs. Hall-Brown, Buttery and Co., Glasgow, to the order of Messrs. Gow, Harrison & Co., Glasgow (of which we gave full particulars in our Launch columns, April issue, page 43), went down the Clyde on trial. Six progressive runs were made on the measured mile at Skelmorlie. The vessel was fully loaded with 4,750 tons deadweight, and with this load on a mean of full speed runs made 10½ knots, and on a mean of runs reducing the revolutions by 12 per cent., she made a speed of 9½ knots. The machinery throughout the day worked without a hitch.

Rembrandt.—On May 8th the new steamer *Rembrandt* (of which we gave full particulars in our Launch columns, May issue, page 91), went down the river, and during the day ran her official trials in the Firth. Throughout the machinery worked smoothly and to the entire satisfaction of the owners' representatives, of whom there were on board—Mr. Heywood Melly, Captain Bird, Mr. Morrin, Mr. Thomson, and Mr. John Russell. A mean speed of 13½ knots was easily attained, which fully realised the expectations of the builders and owners. The vessel during the evening returned to Glasgow, where she will complete her loading for South American ports.

Loch Lintrathen.—On May 9th the steamship *Loch Lintrathen*, which has been built by the Tyne Iron Shipbuilding Co., Limited, Willington Quay-on-Tyne, to the order of the Dundee Loch Line Co., Limited, Dundee, (of which we gave full particulars in our Launch columns, May issue, page 88). Unfortunately, the weather was somewhat unpropitious, but the trial of both vessel and machinery proved in every way satisfactory.

John Coverdale.—On May 10th the large steel screw-steamer *John Coverdale*, built to the order of Messrs. John Coverdale & Son, by Messrs. William Gray & Co., Limited, of West Hartlepool (of which we gave full particulars in our launch columns, February issue, page 475), was taken for her trial trip, when a speed of 11¼ knots was averaged, everything working very satisfactorily. A capital luncheon was provided by the owners, to which ample justice was done, and at which the usual loyal and other complimentary toasts were proposed and suitably responded to. The owners were represented by Mr. Robert Coverdale (managing owner) and Mr. Jas. Airey (who has superintended the building of ship and machinery); the shipbuilders by Captain Murrell, and the engine works by Mr. W. C. Borrowman. After the trial the vessel proceeded to Barry Dock to load for Naples.

Archanda.—On May 12th the steel screw-steamer *Archanda*, built by Messrs, Craig, Taylor & Co., Thornaby-on-Tees, to the order of the Compania Naviera Vascongada, of Bilbao, (Mr. Felix de Abasolo, managing director), (of which we gave full particulars in our Launch columns, May issue, page 89), proceeded to sea for her trial trip, during which the engines worked without the slightest hitch, and gave every satisfaction. The vessel proceeded to the Tyne, under the command of Captain Urizar. The owners were represented by Mr. Jose A. de Mendiguren, who expressed himself as being highly pleased with both the ship and engines.

Tantallon Castle.—On May 15th the *Tantallon Castle*, recently launched at Kinghorn by Messrs. Scott & Co. (of which we give full particulars in our Launch columns), left Leith on her official trial trip. Running down the firth the weather was hazy, but a good run was got to near St. Abb's Head, when the vessel was turned for home. Altogether, however, the trials gave satisfaction to both builders and owners. The distance from the Bass Rock to the Heriot Buoy was done in 59 minutes bringing out a speed of 17½ knots; and from thence the journey to Leith was accomplished at a slightly greater speed. The trials lasted six hours.

an.—Lately there has been completed by Messrs. Rennold- Sons, South Shields, a new twin-screw steam tug, named *itan*, built to the order of the Compagnie Universelle du l Maritime de Suez, and is intended for service in the Suez l, of the following dimensions:—Length, 158 ft; breadth, ; depth moulded, 17 ft. She has been built of steel, r special survey at Lloyd's, and is classed 100 A1. The elling machinery, which is of 300 I.H.P., has been con- ted and fitted by the builders, and consists of two sets of -compound engines, each set having cylinders 20 in., 33 in., 4 in. diameter respectively, with a stroke of 33 in. The act imposed an exhaustive series of trials, which were ed out with success, guaranteed requirements being well led. The *Titan* has sailed for Port Said under the command aptain W. H. Thompson, of South Shields.

glo-Australian.—On May 17th the screw-steamer *Anglo- alian* recently launched from the shipbuilding works of rs. Short Brothers, to the order of the Nitrate Producers nship Co., Limited, London (of which we gave full par- ars in our Launch columns, May issue, page 88), went out rial with very satisfactory results. After adjusting com- s the vessel was taken a series of runs over the measured when a mean speed of 13½ knots was attained.

shman.—On May 19th the trial trip of the s.s. *Irishman* place and proved highly satisfactory, a speed of 10 knots attained. This vessel was recently launched by the e Shipbuilding and Engineering Co., Limited, for Messrs. Kennedy & Sons, Glasgow, and is specially designed for coasting and continental trade. Her dimensions are t. by 21 ft. 6 in. by 9 ft. 6 in. moulded, with a carrying city of 250 tons deadweight. The machinery, supplied by rs. Muir & Houston, Limited, Glasgow, is of the compound ce-condensing type, having cylinders 16 in. and 32 in. by stroke, the boiler working at 120 lbs. pressure.

arwick.—On Saturday, May 20th, the screw-steamer *rick*, built by the Blyth Shipbuilding Co., Limited, for rs. Atkinson Brothers, of Newcastle-on-Tyne, was taken to or her loaded trial trip. The dimensions of the vessel are:— th, 243 ft.; breadth, 36½ ft.; depth, 18 ft. 9 in. She has built to Lloyd's highest class, and is fitted with all modern machinery and appliances for the quick discharging of . The North-Eastern Marine Engineering Co., Limited, Wallsend, have supplied the engines, which are of riple-expansion type, having cylinders 18½ in., 30 in., and . by 33 in. stroke. Various runs were made over the ured mile, the performance of both ship and machinery g every satisfaction. During construction the hull and ies have been under the superintendence of Mr. James es, of Newcastle. After trial the vessel proceeded direct on oyage to Drontheim, under the command of Captain J. I. son.

rton.—On May 20th the s.s. *Barton*, built by Messrs. er & Son, of Stockton-on-Tees, to the order of Messrs. ster & Barraclough, West Hartlepool, made her official trip in the Tees Bay. This steamer is built to carry about tons on Lloyd's summer freeboard, and is fitted with builders' patent trunk, full poop, bridge, and topgallant astle. The steamer is fitted with 6 large steam winches, hich steam is supplied by a large multitubular donkey r, steam-steering gear, steam windlass, &c., her general being very complete, and fully up to present-day require- s. She is fitted with powerful triple-expansion engines by ell-known builders, Messrs. Blair & Co., Limited, of about I.H.P. The trial trip passed off very satisfactorily, there no hitch or drawback of any kind. The owners were sented by Mr. Ross, their superintendent engineer, under supervision the vessel has been built. After the adjust- of compasses, the steamer proceeded on her run round to iff, to load for Singapore.

antsobe.—On Saturday, May 20th, the fine steel screw- ner *Elantsobe*, built by Messrs. Wm. Gray & Co., Limited, Hartlepool, for Senor Ramon de la Sota, of Bilbao, was to sea for her trial trip. She is the sixth vessel built by Gray & Co., for Mr. Sota, and is a sister ship to the *ake*, a report of whose trial we gave in our magazine. vessel has been built to Lloyd's highest class, and her ipal dimensions are:—Length over all, 300 ft.; breadth, .; depth, 20 ft. 2½ in. Her engines are of the triple- nsion type, built at the Central Marine Engine Works of the shipbuilders, and have cylinders 23 in. 36½ in. and 62 in. diameter, with a piston stroke of 39 in., steam being provided by two large steel boilers working at a pressure of 160 lbs. per square inch. The owner was represented by Captain Ricardo Goicoechea and Captain Torres, and the trial was in every way satisfactory, the vessel on its conclusion at once proceeded to Bilbao to load.

Reviews.

A Catalogue.—Messrs. Babcock & Wilcox have issued a very interesting and copiously illustrated book about their patent Water-tube Boilers. It is to a certain extent a trade catalogue; but it is that and a good deal more. It is a valuable contribution to the literature on the vexed question of Scotch *v.* Water-tube Boilers. A long list of vessels of every type designed for every kind of employment, and already fitted with the Babcock boiler, is afforded. We see that several of the fleet of Messrs. Thos. Wilson & Sons, of Hull, certain "turret" ships in the Newcastle and St. Lawrence trade, and ocean-tugs hailing from the Thames are all fitted with this type of boiler on this side of the Atlantic. On the other side, however, the idea has been much more fully developed. Many important vessels trading on the American lakes and a goodly number of the warships which constitute the new American Navy are so fitted. Then, as regards our own Royal Navy, we have the experience with H.M. torpedo-gunboat *Sheldrake*, whose original steam generators have been replaced by an experimental set of the Babcock boilers. This vessel is, naturally under the circumstances, being subjected to a prolonged and exhaustive series of experiments by the Admiralty, and so far the installation has given the greatest satisfaction.

The volume before us contains a reprint of Mr. A. E. Seaton's paper, read in 1897 at the Institution of Civil Engineers' Conference, on "The Use of Water-tube Boilers in the Mercantile Marine." The managing director of so important a shipbuilding and engineering establishment as that of Messrs. Earle's, of Hull, is entitled to speak with authority on such a subject. He seems to think that for high-speed passenger ships and for vessels of the passenger and cargo class these boilers offer great advantages, owing to the saving which they offer in weight, and to the rapidity with which steam can be raised by them—this latter quality being, of course, especially valuable in the case of cross-Channel boats. In a less degree is the advantage of the water-tube boiler apparent in the case of the ordinary tramp cargo boats. But even here a saving of weight in the machinery department—combined with the facility of repair which characterises the water-tube type—has its great recommendations. Two tables are appended to this paper.

The first of these shows the weights, &c., of boiler installations for a passenger steamer whose I.H.P. is 10,000, according as ordinary Scotch (with various draughts), Belleville, Thornycroft, Babcock & Wilcox, or Seaton generators are fitted.

The other table tells of the actual weights and other characteristics of the boilers actually fitted on the Babcock and on the Scotch principle to certain similar ships within a recent period by Messrs. Earle's. Much instruction can be gathered from the study of these tables.

The book contains many illustrations of boilers of the Babcock type and of vessels in which they have been fitted. It also contains much information as to the advantages of such installations, and as to the method of fitting and of working and managing these boilers.

Full descriptions of tests made with the Babcock boilers under stringent conditions both by the American Navy Department and by the British Admiralty are also afforded. We can confidently recommend the perusal of this volume to all who are interested in the practical solution of this great question between the two opposing camps which support the Scotch and the water-tube boiler respectively.

The Sinking of the Merrimac, by Naval Constructor Hobson, U.S.N. London: T. Fisher Unwin, 1899, price 7s. 6d. nett.

Lieutenant Hobson has provided us with a substantial and complete record of the operation with which he was so intimately connected, and which was the one dramatic episode in the recent Hispano-American War. There is much in the volume for us to learn from, much that we can admire, much that will give us food for reflection. We feel that we are taught something of the realities and sufferings of war, and of the causes which led to the destruction of Spanish rule in Cuba from the volume before us. Whatever may have been done with, or to, Lieut. Hobson after his return to his native shores, we do not know. What the newspapers over there said, is here no business of ours. All we can do is to take the man as we find him. In the pages of his book he appears as a modest, thoughtful, and observant man. One, in fact, of the class of men whose self-denial and patriotism acting upon a mind and a physique trained in good schools, abounded in the American forces and so made it easy for good officers to wipe out an inferior enemy.

The marine engineer will be interested especially in the earlier part of the volume. We are told how the obstruction of the Santiago channel by the sinking in it of a big steam collier was determined upon. We learn how, when the *Merrimac* was chosen for the sacrifice, which makes her famous, her officers were found at mess and were naturally incredulous at the statement that that night she was to be sunk under the guns of the enemy's fleet. The discussion of the best mode of securing her speedy foundering at the proper moment is instructive. Three suggestions seem to have been made. The first was the boldest. It was no other than to loosen a plate in each compartment of the ship by cutting off the rivet heads, and to leave nothing to keep the skin in position but the external pressure of the water. At the right time, an explosion capable of overcoming this external resistance was to be provided. This plan, however, had to be discarded because of the length of time which the rivet-cutting would necessarily occupy. Then were considered the relative merits of internal and external explosions for the same purpose. Eventually the laying of internal torpedoes, to be actuated by a battery, was decided upon. The work of stripping the ship, and of preparing her for the purpose for which she was selected, however, took longer than was anticipated, and the stripping, if not complete in every detail, was sufficient to throw great difficulties in the way of those who were to risk their lives in the ship. Too much time was lost, and after the volunteers had actually started upon their perilous mission, they were recalled by signal. We can well believe that a severe reaction followed, and that the twenty-four hours that intervened before the attempt could be renewed were trying indeed to those concerned. When at last the rush was made the attempt failed in so far as the channel was not blocked. Two causes contributed to this result. One was that the fire of the Spaniards cut away the steering chains, the other was the slowness with which the ship actually went down, in spite of all that those on board—aided by the fire of the enemy—could do. The *Merrimac* was carried by the tide down, instead of across, the channel. The chagrin of the Lieutenant as he with his handful of men clung through the summer night to a floating raft attached to the wreck can well be imagined; as, indeed, can be his later satisfaction when he found- on knowledge acquired in his prison—that if he had succeeded in his object of blocking the channel, he would have debarred his country's arms from the victory which they finally and fairly one.

Of the incredulity of the Spaniards—who by their own cross fire had suffered losses which they attributed to the guns of the *Merrimac*—as to the unarmed and almost unmanned condition of the poor old collier, we need not here do more than refer. As to the author's experience in prison we may leave our readers to learn for themselves from the writer's own pages. But we must mention the courtesy with which the gentlemen of Spain treated their captives. Yet at the same time we are afforded indications of the temper which has caused the Spaniard to glide so rapidly down the scale of nations; cruelty, and what is almost worse than cruelty—want of thought—are his characteristics. One's blood boils when one reads of the torture of the little black dog, of the ribaldry of the Spanish soldiery, who enjoyed its agonies, and of the astonishment of the Spanish officers at Lieutenant Hobson's vigorous protest against the outrage. This little touch of kindness to animals marks the Anglo-Saxon and the brave man, and stands in strong contrast to the external polish and formalism of the others, however kind they might have been to him. A vast amount as to the respective characteristics of the combatant nations may be gleaned from the book, and our respect for our sister nation will be largely increased by its perusal. We may add that the volume is copiously and beautifully illustrated. Those who read it will rise from the study with a respect for its author which the newspaper reports of his prowess could not give. His boldness was that of the enduring kind and had its source not in constitutio or in martial training but in conviction and intelligence.

The Naval Annual, edited by the Hon. T. A. Brassey. Portsmouth: J. Griffin & Co., 1899.

The thirteenth issue of this standard publication gains unwonted interest for more reasons than one. Most intelligen people are aware of the costly rivalry that has set in betwee the great Powers in the matter of comparative naval strength Such persons are generally anxious that the enormous interes that England holds in the maintenance of peace with honou should be conserved. Yet at the same time they are, as pruden persons, greatly concerned at the strong upward tendency displayed by successive Budgets. To "Brassey" they turn in th knowledge that there they will find a calm and accurate statement of the present position and future prospects of foreig navies and also a dispassionate review of our Navy's ability, a regards both *materiel* and *personnel*, to do its duty.

From the data here appended it would appear that at the end of the year 1899 the strength of England, as compared with that of the next two most important maritime Powers, will be:—

	England.	France.	Russia.
First-class	23	9	6
Second-class	11	9	9
Third-class	12	15	3
Totals	46	33	18

This is completed vessels. But regarding vessels projected, as well as those actually completed, the numbers are:—

	Battleships.	Coastguard ships.	Cruisers.	Torpedo gunboats.
Great Britain ..	57	23	137	34
France	36	16	52	21
Russia	21	16	28	9
Germany	16	19	24	4
Italy	14	3	21	17
United States ..	13	10	20	—
Japan	7	1	18	—

The writer in the annual seems satisfied with the table as i stands—especially as regards battleships. We are, howeve ourselves doubtful as to whether too many obsolete ships do n appear in the effective list. All navies must contain vesse that are growing old. But an old navy like ours must contai a fuller proportion than those of younger maritime Powers.

There is another matter, however, which makes the iss under review attractive. It is the full account which it gives the recent naval operations between Spain and America. Th interesting account of this war is illustrated by some excellen maps and charts. Another historical question is dealt with i the chapter by an anonymous author—the gunboat operation on the Nile during the recent Soudan campaign. The mention of anonymous contributions leads us to remark on another opportune chapter, of the name of the writer of which no mention is made. This is on the subject of British fortification; what we ought to fortify and to what extent. This subject was dealt with two years ago by no less an authority than Sir George Clarke and some little apology is made for reopening the subject. The recrudescence of what the writer of the chapter calls, somewhat contemptously, the "bricklaying" school has made further discussion desirable. Indeed one of the lessons of the Spanish-American war—as shown by the letters of Captain Mahan himself—was that the timidity, perhaps, not unnatural under the circumstances, of the coast dwellers at home is a factor with which naval authorities must be prepared to reckon, and is one which may hamper their movements at a critical moment when a chance shows itself for a dash upon the enemy.

The *Annual* opens with the usual introductory chapter on the "State of the Navy" from the pen of Lord Brassey. After reviewing the naval expenditure—current and recent—he sums up by saying that the British Navy is "assuredly not falling behind." Turning then to the question of manning, he holds, as he has long held, that the question of Naval Reserves is one that demands the most earnest consideration. He believes that a scheme for training boys for the Navy is essential. What form that scheme should take he is not prepared to say, but he in dicates that some modification of that propounded by the Navy League is most likely to meet the case. He, however, criticises that scheme as it stands, on the ground that it should never pay the shipowner for what he does by giving his support to the plan. In reviewing the question of shipbuilding at home and abroad, Lord Brassey, as usual, pleads for restriction of dimensions. Amongst battleships—whilst he admires the qualities of the *Majestic*—he pleads for the continued representation of the *Canopus* class. So he reiterates his belief that the *Powerful* and *Terrible* are beyond the legitimate displacement of any cruisers. But at the same time he is characteristically fair. The boldness which induced the designer to associate a practically new type of steam-generator with the largest engine ever put into a warship is fully recognised. He asserts, too, that the difficulties which were only to be expected under the circumstances with the machinery of these vessels has now been entirely overcome. Further, in relation to the question of size he notices the comparisons which have been made—to the disparagement of our naval ships—between war vessels built at Elswick and those designed by Sir William White. He emphasises the point —which should have been sufficiently apparent—that the greater displacement of the latter vessels gives them substantial advantages in directions which in the British Navy, at least, are of essential importance. He traces out, too, how from the lessons first taught at the Yaloo we are being shown that protection at the waterline is not the only essential in a warship, and that we are giving the superstructure of our new cruisers greater protection.

One of the lessons of the operations last year seems to have been the comparative inutility of the torpedo, and accordingly it seems likely that in the future these weapons will not be carried in any but torpedo craft. The same experience also shows the value of the mercantile armed cruiser. Immense benefit was derived by the United States from the assistance of the vessels of the American Line, though it is suggested that full use of their capabilities was not made. In this connection a point, which needs some qualification, is made against the auxiliary cruiser. It is stated that "vessels of this class [referring to the *St. Louis* at page 170] carrying 200 lbs. of steam in cylinders 14 ft. above the water-line are clearly unsuited for regular fighting purposes." We are not in a position to check the accuracy of this statement as to the level of the cylinders of the *St. Louis*. But we do know that the weakness here suggested does not infect all the auxiliary armed cruisers retained by the British Government; for the *Teutonic* and *Majestic* at least have the top of their cylinders below the water-line, and we believe that the same might be said of the *Lucania* and *Campania*. But the value of these auxiliaries in spite of the alleged weakness referred to is strongly insisted on. "The *St. Louis*," it is said, "went to sea with one quarter of her displacement in coal, and for six weeks never took on board any coal, water, or provisions. The publicists who have dwelt on the injury to Great Britain due to the abandonment of privateering may perhaps be induced to reconsider their position. For operations against commerce such vessels as the *St. Louis* and *St. Paul* in capable hands are necessarily formidable." The auxiliary armed-cruiser idea apparently recommended itself—at least in theory—to the Spanish also. They purchased from the Hamburg-American Line the *Normannia* and the *Columbia*, and the *Havel* from the North German Lloyd Co., not, as the *Annual* tells us, from the Hamburg Co. But they never had the energy to fit the vessels out.

The discussions as regards the further use of nickel steel, of the advantages of the triple-screw and of the turbine engine, are the main points in Mr. Dunell's most valuable contribution to the history of the year. The use of nickel, though much to be recommended, seems practically debarred by its high cost. The triple-screw has found a warm supporter in Commodore Melville, of the United States Navy, even though our own Admiralty seems to find good grounds for deferring adhesion to it. The present authorities are responsible for the universal adoption of the twin-screw in the Royal Navy, and thus should be assumed to look with *a priori* kindliness on the triple principle. We may justifiably assume that they have the best of good reasons for not doing so. The discussion of the turbine engine leads to a remark upon the importance of an absence of vibration in machinery, and we note that in another part of the same chapter the Yarrow-Tweedie-Schlick system of balancing is referred to. Attention is called to the serious demands now made by auxiliary machinery on the coal supply of warships, and a suggestion thrown out that economy may be effected by the use of electricity for all auxiliary purposes—cables being led from a central generating station. The danger arising from cut steam-pipes in action is alluded to, and the advantage of cables insisted upon, since no danger is caused by the fracture, and repairs are more easily and quickly effected. The famous run of the U.S.N. battleship *Oregon* is alluded to as a triumph for the naval engineer. It is a triumph of a humdrum kind perhaps, but it is this mastery of routine duties and attention to detail which lays the necessary foundation of success in emergency.

The whole volume—as will be seen from our imperfect review—is worthy of the reputation of its predecessors, and of Lord Brassey.

Terek.—On May 24th this vessel was launched by Sir James Laing & Sons, Limited, at their works, Deptford Yard, Sunderland. She is the first of three steamers being built by that firm to the order of Messrs. Lane & Macandrew, of London, on behalf of Messrs. La Societe Commerciale et Industriale de la Naphte Caspienne et de la mer Noire, of Paris, and is especially designed for the carriage of oil in bulk. This vessel and her sister-ships are being constructed under the immediate supervision of Messrs. Flannery, Baggallay & Johnson, of London and Liverpool, and are to obtain Lloyd's 100 A1 and the highest class of Bureau Veritas, to conform with the Suez Canal regulations for oil steamers. The principal dimensions are; 325 ft. by 45 ft. by 29½ ft. depth, moulded, and the engines, constructed by Messrs. George Clark, Sunderland, have cylinders 24½ in., 40 in., and 66 in. diameters respectively, with a stroke of 45 in., taking steam from two large single-ended boilers working at 180 lbs. pressure. Electric light is fitted throughout the vessel, and the pumping installations are especially handy and powerful, and is capable of dealing with oil cargoes with great rapidity.

Celtic Princess.—On May 24th there was launched from the shipyard of Messrs. Robert Thompson & Sons a finely-modelled first-class cargo and cattle steamer for Messrs. R. Hughes-Jones & Co., of Liverpool. Her dimensions are:—Length over all, 347 ft.; breadth, 46 ft 2 in.; depth, moulded, 28 ft. 6 in.; to carry about 5,600 tons deadweight on a light draught, and will on completion have Lloyd's 100 A1 class. She is constructed with poop aft, long bridge amidships, and topgallant forecastle, the poop and bridge being for light cargoes if required. There are five holds with large hatchways and powerful steam winches, also double derricks to each for the rapid loading and discharging of cargo. The accommodation for captain, officers, and engineers is placed amidships in large and spacious houses on top of bridge deck, the saloon and captain's rooms being neatly fitted up in different shades of oak, the crew and petty officers being berthed in forecastle. The water-ballast arrangement is on the cellular principle, with the addition of peak tanks, and is sub-divided both thwartships and longitudinally for trimming purposes, special attention being paid in this instance to have the tail-end shaft very short, so as to lessen the risk of breakage when crossing the Atlantic in ballast. The engines having cylinders 24 in., 39 in., 64 in., with 42 in. stroke, with very large boilers, are by the North Eastern Marine Engineering Co., of Sunderland. As the vessel left the ways she was gracefully christened *Celtic Princess* by Mrs. R. Hughes-Jones, wife of the managing owner.

The new Swansea dry dock which was opened lately, has an extreme length of 455 ft., and a width of 116 ft. between copings. The entrance is 60 ft. wide, and the depth of water on sill is 15 ft. at ordinary neap tides and 23 ft. at spring tides. The water will be pumped out by two powerful centrifugal pumps, 36 in. in diameter, capable of discharging 420,000 cubic feet of water per hour, and these pumps can empty the dock in about two hours at spring tide and an hour and a-half at neaps.

The Marine Engineer.

LONDON, JULY 1, 1899.

SHIPPERS and steamship owners have particular interests in the competition of colonial or foreign coalfields with our own supply. Of foreign supplies those of Pennsylvania, Russia, China, and Japan are at present most prominent; and of colonial fields those in South Africa—which are estimated to extend over 56,000 square miles in Cape Colony, the Orange Free State, the Transvaal, Natal, and Basutoland—with those of New South Wales and India, are the most important. The export coal trade is very sensitive as to rumours of such colonial or foreign competition, but weight for weight and calorific value with minimum of ash there is as yet little direct competition with our best northern and Welsh coals, especially for the marine service. A special commissioner has been appointed by the Cape Government to report on the South African coalfields, which he has reported are of vast extent, and as to their relative value for marine purposes in competition with British exports. Indwe coal, the best in the colony, with Stormberg next, he reports to be a valuable fuel for any purpose so long as it does not come into serious competition with a better article. The percentage of ash is, however, about 20 to 30 per cent., and the volatile constituents are also about 30 per cent., which must much reduce the value of this coal for steam-raising purposes where excess of ash is a nuisance and liable to choke the fires. It is estimated that one and half ton of such coal would be necessary to give the same evaporation as one ton of Welsh; and in the marine or naval services the extra weight to be carried and the tendency that the rate of evaporation for a given grate-area would be much diminished as compared with Welsh or hard steam coal, is not likely to render such colonial coal of service in any lines where speed is a desideratum, or when net-paying freight is desired to be of the largest proportion. Special grates with rocking fire-bars have been used on the eastern railways to enable this fuel to be used locally, and it is at least comforting to know that for many purposes the drain on our own coalfields may be relieved by such large stores of coal in our own colonies.

WATER-TUBE boilers are at last making their mark in steamers for passenger-carrying only. The first set of water-tube boilers passed by the Board of Trade for service in a purely passenger-carrying steamer was, we believe, the case of the *Meg Merrilees*, belonging to the Caledonian Steam Packet Co., about June last year. The special type of steam-generator in this case was the Haythorn water-tube boiler. We now note that boilers of the same type have been applied to a South of England pleasure steamer, the *Lorna Doone*, added by purchase by the Isle of Wight Royal Mail Steam Packet Co. to its existing fleet of steamers. The *Lorna Doone* was built in 1891 by a Glasgow firm, Messrs. Napier, Shanks & Bell, and engined by Messrs. D. Rowan & Son, of the same city, her gross tonnage being 427 tons. The old boilers were replaced after her last season's service by water-tube boilers, and with radical improvements to the engines, under the direction of Mr. C. W. Murray, M.I.N.A. The new boilers are characterised by a second combustion-chamber just below the main body of the tubes, and they serve to utilise a large proportion of the heat of the gases of combustion before they reach the base of the chimney. The heating surface of the new boilers is about double that of the boilers they displace, and the fire-grate is considerably increased in area. The second combustion-chambers also prevent the possibility of cinders or soot particles finding their way to the funnel, a great boon in a passenger steamer. The *Lorna Doone*, with her new equipment, has just run a trial trip with a large party of guests on board, when it was found that the boilers provided an ample supply of steam, and the combustion appeared perfect, there being an entire absence of flaming in the funnels. So far, therefore, the application of water-tube boilers—of which in this vessel there are three, two forward and one aft, with the stokehold between—has proved eminently satisfactory both to the crew and the passengers; and it would appear that the water-tube boiler as a type is every day increasing its field of application and usefulness, and appears as if it had come to stay. The crucial test of this type of boilers can, however, only be settled by lapse of time as regards their relative durability and ease of handling in regular work.

WE think it would be well if our Admiralty were to reconsider their present predilection for the Belleville type of water-tube boiler. No doubt, from the early date of introduction of this boiler, it has a longer record than others as regards practical experience, but that it is the best form of water-tube boiler amongst those now generally in use is at least open to grave doubt. We were much astonished to see the other day the large extent to which the Yarrow type of boiler has been adopted in the Dutch Navy. No less than six cruisers are fitted, or being fitted, with Yarrow boilers of 10,000 H.P. each. Two battleships, one afloat and one in hand, are supplied with Yarrow boilers of 6,000 H.P., and two torpedo-boats have Yarrow boilers of 1,000 H.P. each. If the Dutch Government have thus selected this type of water tube boiler as the best, there must be something in it; and these boilers are also favoured by the Russian Government, and are being put into Portuguese and Norwegian cruisers by the great Elswick firm. Apparently then these competent judges have decided that they need not go either to France or the United States for what they consider the best type of water-tube boiler. We also must not forget that H.M.S. *Salamander* has been fitted with Mumford water-tube boilers, which have made a very good record. There appear to be two distinct types of water-tube boilers: those with short, steeply inclined or nearly vertical tubes, which, when allied with very thin sections, may be termed express boilers; and those with larger, almost horizontal tubes of thicker sections; and so far, for large steamers and for naval cruisers, the latter type has been considered to a large extent the only type suitable. It is, however, held strongly by expert opinion that the latter part of long water-tubes is of little value for evaporation as compared with the first part of such tubes; and for evaporative efficiency comparatively short, steeply inclined tubes are probably more efficient. It is well worthy of consideration whether the express type of water-tube boilers—such as those of Thornycroft, Yarrow, and Normand, modified as to section and diameter of tubes for greater durability where a minimum of weight is not so essential as in torpedo-boats or destroyers—may not be the better type, when properly modified, for cruisers and battleships.

We are in a revolutionary age in mechanical design, owing to the quick evolution of scientific research and invention. The problem of the steering and control of torpedoes through an unconnected distance, such as from a vessel or from land, has, it is said, received a practical solution from a young Swedish inventor. Surely the inventive genius of the men of to-day in perfecting weapons of offence is war's most deadly foe. The cold-blooded scientific slaughter of opposing forces will make such conflicts too murderous to be characterised by the chivalrous name of war. A Mr. Axel Orling, in conjunction with a Mr. J. T. Armstrong, of London, has discovered a new way of transmitting motive power by means of light, the rays employed being those ordinarily invisible, as in the X rays. Such rays may thus be used invisibly from a controlling station, either on board ship or on land, to control and steer, if not to impel, a submerged torpedo; and to determine at any time the discharge of a detonator, by which the explosion of the torpedo can also be determined at any moment by the control. All that is required for the receipt of the controlling rays is a white disc mounted on a shaft projecting from the torpedo above the water. At night time the projecting rod carries an electric light as an indicator of position to the control, whilst shaded and protected from the observation of the enemy. This invention is not merely a matter of theory, but has been tested experimentally in Swedish waters, where, by command of the King, torpedo-boats and torpedoes were placed at the service of the inventor—somewhat a contrast to the ungracious and repressive manner in which our Admiralty receives any offer to experimentally test new inventions. We understand, as a result, the Swedish Government have decided to take up this invention, and have acquired the Swedish patents. Mr. Orling, we understand, is now engaged in working out an idea for an air-torpedo to be controlled by the new rays. If the young Swede's expectations should be realised, it would appear that both land and naval warfare, as at present known, would be revolutionised, if not rendered impossible.

GOSLING'S FORCED DRAUGHT.

THIS method of forcing draught is of an extremely simple nature, as is shown by the figures in illustration of its application to the furnace of a water-tube boiler. It consists of a horizontal tube, Fig. 1, placed along the front of the ash-pit with tubes at right angles to this under the fire-bars. These tubes under the fire-bars have a bell-mouth, and a nozzle attached to the tube in front of the ash-pit blows steam into them, inducing air to follow and mix with it. The tubes under the fire-bars are perforated, and the mixed air and steam is blown through the fuel above the bars. These tubes under the fire-bars are about 4½ in. diameter. The hole in the steam nozzle is 1-16 in. diameter, and the steam to supply these is obtained from the boiler, as shown in Fig. 2. The fire-bars are placed close together, the distance between being only about ⅛ in.

This type of forced draught is an aid in the case where the chimney is insufficiently high, and it also enables the commonest classes of fuel—such as slack coke, breeze, dust coal—to be used efficiently, and the makers claim that as high an efficiency is obtained from this poor coal as is obtained from the best when burned under ordinary conditions. It is also claimed that, whatever kind of coal may be used, the fire-bars remain free from clinkers adhering to them, and there is thus less waste of fire-bars, which is a serious item in ordinary cases. There is a more equable distribution of consumption of the coal over the area of the fire-grate. and there is not the same tendency to holes being formed in the fire as in ordinary cases. This formation of holes acts very seriously against the proper consumption of the fuel, and is wasteful in its application of the air of combustion. In such cases the air goes through the bare places, and does not mix sufficiently amongst the gases to be consumed, and thus passes up the chimney as mere heated air, which reduces the economy of combustion. Sometimes also, where the air is supplied under pressure, there are back explosions; and to prevent these the draught has to be shut off before the fire-door can be opened. The furnace-door may be opened with safety with this type of forced draught.

With Gosling's forced draught no fans, engines, movable or perforated bars are required. Several tests have been made to demonstrate the advantage gained by the use of this system of forced draught. The following is given by the makers as having been conducted:—

NATURAL DRAUGHT WITH SMALL COAL.

lbs. of coal consumed.		gallons of water evaporated.		lbs. of water evaporated per lb. of fuel.		cost of coal per ton.		cost of evaporating 1,000 gallons.
72,128	..	45,852	..	6·25	..	9s. 6d.	..	6s. 8d.

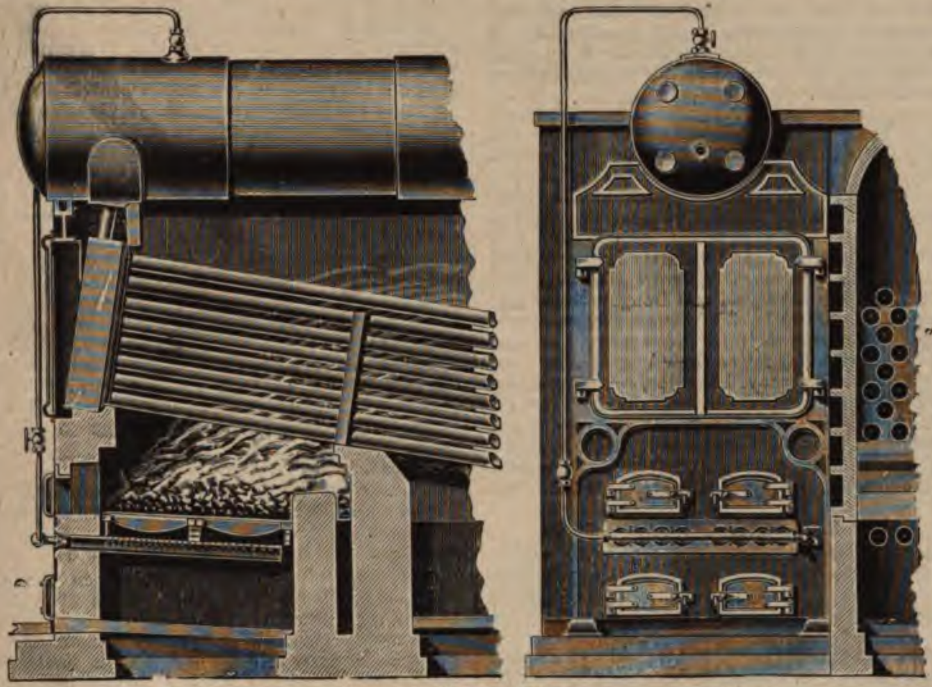

FIG. 1. GOSLING'S FORCED DRAUGHT. FIG. 2.

FORCED DRAUGHT WITH SMALL COAL.

59,534	..	47,224	..	7·92	..	9s. 6d.	..	5s. 4¼d.

In another case where a trial was made, with this system fitted to one Lancashire boiler and ordinary draught to the other; the boiler with the forced draught evaporated 606·9 gallons of water in half-an-hour, whilst the boiler with natural draught evaporated 469·6 gallons in the same time.

An advantage of the system, which is designed and manufactured by the Forced Draught Syndicate, 73, Queen Victoria Street, London, is that more power can be obtained from a series of boilers without the necessity of increasing their number.

Institution of Naval Architects.—The summer meetings of this Institution will be held at Newcastle-upon-Tyne and Sunderland, on Tuesday, July 18th, and the four following days. The Right Hon. the Earl of Hopetoun, G.C.M.G., will occupy the chair. Papers have already been promised by Sir Andrew Noble, K C.B., on "Naval Artillery"; Mr. P. Watts, on "Elswick Cruisers"; Mr. H. F. Swan, on "Ice-breaking Steamers"; Mr. F. Marshall, Jun., on "The Boiler Arrangements of some Recent Cruisers." A paper has also been promised by Mr. A. F. Yarrow, and a joint paper by Herr Otto Schlick and Mr. John Tweedy.

THE FLEETS OF THE MAIL LINES.

(From our own Correspondent.)

Lane Routes.

ON the authority of the master of a Norddeutscher Lloyd liner, the New York correspondent of the *Shipping Gazette* makes a serious charge against the Anchor Line s.s. *City of Rome*, and against those who are responsible for her management and navigation. It is said that the Norddeutscher liner in question bound west sighted the *City of Rome* bound east, and that this fact proved that the latter was thus to the south of her lane route. The fact of the sighting is not denied, so the story goes. But the explanation is given (*a*) that the Anchor Line was not a party to the agreement whereby the lanes were adopted. To this it may be said that neglect to join the agreement does not prevent people from following the course recommended by the united wisdom of the principal owners of the mail-boats of the world. (*b*) Then it was urged that the vessel was not bound to the same port as the Liverpool liners. This contention is obviously true, but there is absolutely nothing in it. It was true also of the Norddeutscher steamship which reported her. But the fact did not prevent the German boat from keeping the track for a considerable part of her run. It would affect the *City of Rome*, too, less than the German boat, on the east-bound course at least, for, whereas the German vessel was bound to the English Channel, the Anchor liner's destination was Moville at the North of Ireland. Lastly, the agents of the line say that the vessel was doing as she did because she had orders to go far south to avoid ice. A most laudable purpose is that of escaping possible risk; but the lanes themselves are laid out with the full knowledge of the ice and its dangers, and that defence therefore amounts to little. In point of fact the *City of Rome* seems to go very much as her fancy directs her. I have noticed her as reported from Cape Race on more occasions than one. It is very much to be hoped that the publicity now directed to her manœuvres will cause her and the Anchor vessels generally to follow the usual practice of the trade, and keep to the lanes, for dissent from the general practice by a few vessels largely nullifies the precautions of the great majority. Possibly a reminder of the fact that going out of the lane is sometimes fatal to the vessel which chooses her own course may be an argument which will appeal to those whom nothing else will move.

Last Month

I stated that there was a rumour afloat that La Compagnie Générale Transatlantique was about to buy the old Hamburg-American liners *Columbia* and *Normannia* which Spain bought at the time of the war with America, and did *not* use as auxiliary armed cruisers. I mentioned that there were certain obstacles in the way of their use by the French company in consequence of the fact that the arrangements with the French Government under which their mail subsidy is receivable forbids the employment by them of foreign-built ships—both the *Columbia* and the *Normannia* were built in the United Kingdom—for their mail service. There are obviously great difficulties in the way of a company which proposes to buy vessels of a class superior to any vessel in their fleet, save one, when the vessels in question are absolutely debarred from sailing save as extra and occasional boats, and are thus incapable of serving as a stand-by in case of emergency. So it is not surprising to hear it reported that the *Columbia* has been repurchased by her original owners, the Hamburg-American Line.

The Old "Ireland,"

whose sale by the City of Dublin Steam Packet Company I reported last month, is to be employed in the annually renewed attack on the preserves of the Isle of Man Steam Packet Company. This company "asked for it" when it bought off opposition in previous years. It has got it. One of the last assaults was threatened by the employment of the now nearly forty-year-old paddlers replaced by the present twin-screw Holyhead and Dublin mail boats. Now the Liverpool and Douglas Steamers, Limited, whose capital is £50,000 in fifty-pound shares, comes fresh to the attack with the *Ireland* in the front rank. Amongst their powers I notice the right (as far as their shareholders are concerned) to carry troops. Do they, I wonder, contemplate an actual invasion of Hall Caine's Little Man Island? At all events, though their ship is a fairly good one, they have a vessel that simply eats coal with her single-expansion paddle-engines, and the coal bill may perhaps prove an obstacle in their way when they come to a close grip with their old established rivals.

A Pilot Sued.

Judge Shand, of the Liverpool County Court, has just had a very unusual suit tried before him under the Admiralty jurisdiction of his court. In December last a collision took place in the river Mersey between a small steamer, the *Elsa*, and the big Transatlantic steamer *Rossmore*, now lost in the Atlantic. A collision case came in the usual way before the Admiralty Division of the High Court. In it the *Elsa* was found solely to blame; but her owners were freed from their liability because of the fact that at the time the accident happened their steamer was, by compulsion of law, in charge of a pilot. So failing to get any compensation out of the owners, Messrs. Johnson have sued the pilot. The facts of the case were again gone into, but the county court judge, like him of the High Court, found that the *Elsa* was alone responsible, and so the pilot of the *Elsa* was held personally liable for the damage sustained by the *Rossmore*. This adds a new terror to service in the mercantile marine. The liability has ever been there. There is nothing new in the law. But it is still quite a new departure to bring in the personal responsibility for his acts to the working man of the ship. The pilot is hit here. But it should not be forgotten that circumstances might be conceived easily enough under which the navigator or the engineer on duty might find himself responsible to owners of a colliding vessel for default in his particular work.

"La Bourgogne."

Whilst touching on legal matters it may be interesting to mention that the appeal of La Compagnie Génerale Transatlantique against the finding of the English Courts—that they, as carrying on business in London, were amenable to our law for the damage occasioned to the *Cromartyshire* by the collision between her and the ill-fated mail steamer *La Bourgogne*—has been carried to the House of Lords. But the French company found no relief. The Lord Chancellor expressed his admiration of the skill which enabled counsel for La Compagnie to make bricks (or something that looked like bricks) without any straw whatever. But he and his august brethren could see no ground for reversing the decision of the courts below, and so, as far as can be gathered, the game is finally ended in favour of the *Cromartyshire*. I trust this may be the last occasion on which it is necessary to refer to this very sad history.

The Russian Volunteer Fleet

will yet have further assistance from its Government in the future. It has been decided that, with a view of encouraging Russian trade and navigation in the Pacific, the State shall for the next 10 years pay the dues of all Russian merchant steamers passing through the Suez Canal. This is a substantial concession indeed, and it should be a very great assistance to that already highly subsidised auxiliary to the Russian Navy. But it is possible that the effect of the bounties—for such in fact they are, though they may be somewhat disguised—will be such as to induce purely merchant steamers to trade under the Russian flag and may thus bring some competition into the freight market for steam tonnage between Odessa and Vladivostock. In that case the encouragement now given might prove rather a doubtful blessing to the patriotic organisation. At all events it is likely to do British shipbuilders a good turn indirectly; for those who direct the volunteer fleet are in the habit of putting all their surplus earnings into new tonnage, and so it is probable that most of the money contributed by the Russian taxpayer for the encouragement of Russian trade to the Pacific will eventually be spent in the shipbuilding yards of the Clyde and of the Tyne.

The Accident to the "Gallia"

seems likely to be a more serious matter for those interested than was at first suspected. The vessel went ashore on mud in the St. Lawrence and took no hurt as far as the contact was concerned. But she was going up stream at the early part of the period of open navigation, when the water is at its highest. The work of lightening her was at once commenced, but even quicker than she rose the water fell. Where she lies will, it is said, soon be an island and cattle will be grazing alongside the stranded liner if she is not got back into deep water. Every effort is being made to avoid so serious a delay as a summer's stay in the St. Lawrence would involve. But the work progresses slowly. A deep channel has to be dredged for the passage of the ship; and it is said that, in order to enable her to work on the landward side of the *Gallia*, the dredger has first to scoop out a channel for herself. As we go to press, it is reported that she was safely floated on the 24th June, and is en route for Montreal.

The New "Oceanic"

is causing a good deal of movement in the *personnel* of the White Star Fleet. I announced some little time ago that Mr. Sewell, the commodore engineer of the line, was to have her machinery department in his charge. Now a movement has begun towards providing her with a navigating staff. The *Britannic*, which left Liverpool on the 21st June, had a new commander. He is Captain Hayes, till recently chief officer of the *Teutonic* and brother of the well-known skipper in the Pacific Steam Navigation Company's service. Captain Haddock leaves the *Britannic* for the *Germanic*, and her late commander, Lieutenant McKinstrey, R.N.R., gets the *Teutonic* in relief of Captain Cameron, who is to have the new leviathan. Speaking of the *Germanic* brings me to note that this vessel is once more in harness and is probably a better ship to-day than she has ever been in her long and popular career. After her unfortunate accident in New York harbour, when the weight of the frosty accumulations of the famous blizzard were too much for her as she lay in her dock, she was, as is probably not forgotten, brought back to Belfast under her own steam, though without passengers. She arrived there on the 17th March after a remarkably good passage, which showed conclusively enough that, whatever else might have suffered from her immersion, the machinery was in a highly satisfactory condition. At Belfast her builders, Messrs. Harland & Wolff, have given her a through overhaul, and on the 3rd June she came back again to Liverpool. That port she left on the 7th of the month, making a good passage outwards in the mail service to which she is now so happily restored.

The P. & O. Meeting

gave Sir Thomas Sutherland an opportunity of breaking gently to his shareholders something of the bill which they will have to settle for the disaster to the *China* last year. The first item must be the expenses which the owners themselves had to deal with locally in the Red Sea in their attempts to get the ship afloat and in the work of compensating passengers for their claims for property lost. Nothing is said about that.

But we are given evidence of the fact that if the ship was originally a very valuable one, the accident and her restoration to active service will be fully in proportion. The salvors were settled with for the record sum of fifty-seven thousand pounds. This sounds a lot of money, and is certainly a big sum to pay for the getting-off of a ship which when floated was of so doubtful value. But I do not think it necessarily a very satisfactory sum for the enterprise of the salvors, whose best men and best plant were on the job for about five months. Perhaps as time goes on we may get some indication of what the expenses of the temporary repairs at Perim and the final overhaul at Belfast amount to, and so may arrive at an appreciation of what the P. & O. will have to pay for the honour and glory of saying that the vessel was not a total wreck. Sir Thomas—as it is worth while to notice—takes some credit to himself for the fact that the ship is now in a fair way to restoration. I can understand credit being given for that fact to the builders, who put such good work into her as to enable her to withstand the experience or to the salvors who so skilfully blasted the rocks from under her. But there seems to me to be small praise due to the man who merely pays the bill for these things, especially when the total of that bill looks like being out of all proportion to the value which his shareholders are likely to gain from the affair. A worse thing is, however, in store for the "premier" line.

Messrs. Ismay, Imrie & Co.

have announced that on August 3rd their new twin-screw steamship *Medic*, of about 12,000 tons gross, will inaugurate a new White Star service from Liverpool via the Cape of Good Hope to Australian ports. The new adventure will, at first, make monthly sailings, and the re-entry of so famous a line into the Australian competition will make it very bad indeed for some of those who are already there. It is interesting to remember that after all this is a re-entry and not a new departure. The line has been in steam just under 30 years. But for a long time ere that period the house-flag was well known in the Australian trade with its clipper ships, amongst which were the famous *Red Jacket* and *White Star*. Even comparatively recently the firm had sailing vessels which they used as training ships for their navigating officers, and many of these vessels were in the Australian trade. Now we see what the building of the *Afric*, the *Medic*, and the *Persic* meant, and learn that two other sisters, to be respectively known as the *Runic* and the *Suevic*, are also on the way. These vessels will be practically sisters, and the five should make it possible to give a four-weekly service of twin-screw cargo boats from Liverpool to the Antipodes. The boats are of a high class hitherto quite unknown in the Australian trade. There are, of course, twin-screw mail steamers in the Norddeutscher-Lloyd and the Orient fleets, but none of these vessels approach the *Medic* and her sisters in size. These ships will be the largest ever seen in those waters. For their carrying power they will be cheap to run. The expense of the Canal dues will be escaped. They steam a good speed at a very economical rate of coal consumption, and should be able to shift cargo at the minimum of cost. Large refrigerating installations are to be fitted to them. This explains why the *Medic*, the second of the family launched, is to make the pioneer voyage; for her elder sister, the *Afric*, after making a run to New York, went back to Belfast to have the refrigerating machinery put aboard, and so she is not as forward in that direction as her younger sister. If sufficient freight be forthcoming to adequately fill these ships, they should prove very beneficial to their owners. Their success would be a great benefit to Liverpool and the busy manufacturing districts behind it; for Liverpool, so long without direct steam communication with the Antipodes, will be able to compete with London on advantageous terms for the carriage of the Australian wool to the northern manufacturing towns. The saloon passenger business will not be much disturbed by the new service, as the carriage of first or second-class passengers is not contemplated. But the third-class passenger will have an opportunity indeed. He will have the big ships to himself. His fare to Sydney will vary according to accommodation, from 14 to 17 guineas. The lower figure is that for passengers who travel in open berths. An extra two guineas will put such travellers in enclosed two-berth rooms, and a further spring of a guinea—to 17—will give them the privacy of two-berth cabins. The Cape can be reached for nine guineas. I have seen illustrations of the accommodation, and it is surprising indeed. The enclosed staterooms are fitted with comfortable berths, pegs for clothes, mirrors, and washband basins. There is a dining-room the full width of the ship, with the revolving chairs which were considered such a boon to the saloon passengers when they appeared aboard the old *Oceanic* in 1871. There are smoke-rooms and reading-rooms. Luxury is naturally absent, but the arrangements for comfort and cleanliness are remarkable. The panels in all the rooms are ventilated, and the seats in the public apartments may be described as of the garden chair pattern, which is cool, comfortable, and clean. In the reading-room there is even a piano. The scale of food offered is most liberal, and to many of those who travel by this line the accommodation and treatment will be quite beyond anything they have ever experienced ashore. The trip aboard the White Star boat will be looked back to as one of the pleasantest episodes in the emigrant's life.

Lord Kelvin

has added another to the many benefits he has conferred on those who go down to the sea in ships. This time it is not by invention that he offers safeguards to life and property. It is by using the position in Parliament which his high scientific attainments have won for him for the purpose of endeavouring to minimise the rush and pressure of speed of modern mail steamers, so that the danger of stranding or collision through fog may be decreased. On the 26th June he will, in his place in the House of Lords, ask her Majesty's Postmaster-General whether it be true that some of the mail contracts entered into by the Post Office with steamship owners stipulate for the performance of the service in a stated time with a penalty for occasions where such time is exceeded, together with a bonus in some cases for a certain diminution of the length of passage. Then he will ask whether in such contracts there may be inserted a saving clause remitting the penalty in cases where the lateness of arrival is due to the taking of seamanlike precautions for the safety of the ship. His question will in fact be a protest against the insertion in any mail contracts of such clauses as that which stipulates that "such penalties are to be inflicted from whatever cause arising." It should bring about the much needed reform of making it clear to the minds of those responsible for the safety of a vessel that the owners cannot in future suffer at the hands of one branch of the Government for the observance of the precautions which the safety of the adventure and the laws of another department of the State enjoin.

A New Seaside Service.

The amalgamation of the two railways which serve the county of Kent is now to all intents and purposes approved by Parliament, and we may soon expect to see further changes in the cross-Channel services which have hitherto been in competition with one another. The joint railways (who might with very good reason work under a much shorter name than that which they now bear) announce a new service which is likely to be very popular with excursionists. Every day of the week there will be run a steamer from Port Victoria to Margate and Ramsgate and back. In connection therewith a train service both up and down will be maintained from Charing Cross and London Bridge, so that those who patronise it will be able in the course of a day to get a good sea blow, and at the same time escape the tedium and delay of the river part of the journey. The idea seems a good one, but, unless facilities bring immediate expansion of traffic, it is somewhat calculated to interfere with the success of the work which during recent seasons has been so ably carried out by the steamships of the New Palace Steamers, Limited.

The "Paris'

at the time of writing is still on the Manacles. The Liverpool Salvage Association was not long suffered to continue its efforts for her release. Operations were taken over by order of the underwriters—to whom, I believe, the ship was early abandoned—by the London Association, and they had, after a time, to call in the assistance of foreign wreckers. The attempt to tow the vessel off at the high tides about the 25th May were unsuccessful, although half-a-dozen tugs were employed and the vessel's own engines were also worked astern. On the 26th the ship began to leak considerably in the engine-room, and on that day the weather became quite unfavourable, the ship moving a good deal in her uneasy bed. On the 3rd June the German salvage steamer *Berthilde* arrived and commenced work. Blasting operations for the removal of the rocks were continued, and platforming was also pressed forward in the damaged holds. But another gale sprang up on the 8th and the vessel filled, whilst her stern was also shifted about twenty yards further inshore, making her position much more difficult for the wreckers. She was now believed to be very badly damaged and her forward boilers were reported as lifted. She rolled so much that at one time it was thought she would go to pieces. Later reports, however, seemed to minimise the damage she had sustained at this time, and energetic means, by the supply of large pumping installations, were taken to cope with the influx of the water. On the night of the 19th she again had to be filled because another gale sprang up. The damage, however, on this occasion was believed to be slight. But the constant grinding on the rocks, together with that which she must have sustained through the fruitless attempts to drag her off by main force, must be serious indeed.

Details respecting the policies in force with regard to the *Paris* have transpired. From these it appears that the ship was insured for about £225,000. The bulk of the risk was taken by American offices, chiefly in Boston. It is said that altogether some forty offices are affected by the accident.

Mr. Smalley, the New York correspondent of the *Times*, had an interesting article the other day in this connection. He spoke of the *Paris* as being what the Americans would call a "tired ship," owing to the amount of labour which she had got through in her comparatively short working life, and to the pressure under which she had been run. He spoke of the way in which she had been driven against heavy head seas to the great discomfort of passengers and to the detriment of the ship herself. This policy of driving under such circumstances he most strongly deprecated, and contrasted it with the experience he had had in bad weather aboard British liners. He told how the *Germanic* and the *Lucania* had been eased down by their commanders in exceptionally heavy weather with results most satisfactory to all on board, and assured the managers that such action was appreciated by the customers of steamship owners. Curiously enough this article was shortly followed by a somewhat significant announcement, though I do not suppose that there was any case of cause and effect. It was a mere coincidence, and there can be no doubt that the managers of the American Line had arrived at their decision long before they read Mr. Smalley's remarks. They announce that a new steamship to supply the place of the *Paris* is about to be built by Messrs. Camp, of Philadelphia. The new vessel is said to be intended to have a length of 600 ft.—about that of the Cunarder *Lucania*—and to have a more moderate speed than some recent additions to the fleets of the mail lines. The American Line managers are reported to have come to the opinion already acted upon by Mr. Ismay in the building of the *Oceanic* that greater comfort at sea is more desired by passengers than increase of already excessive speed.

A Shipbuilding Amalgamation.

Early in the month of June it was reported that, following on the absorption of the Naval Construction and Armaments Company, of Barrow, by Messrs. Vickers, Son & Maxim, there was to be an amalgamation of the Clydebank Engineering and Shipbuilding Company, Limited—which, under the original name of J. & G. Thomson, had built, amongst other famous vessels, the *New York* and the *Paris*, as well as all the London and South-Western Railway Company's recent channel boats with Messrs. John Brown & Company, of Sheffield. The latter firm was established in the year 1864, and has earned a world-wide reputation for armour-plate manufacture.

Here may also be mentioned that Messrs. Scott & Co., of Greenock, which claims to be the oldest shipbuilding concern in the United Kingdom, has just become a limited company. The firm has built many vessels for Mr. Alfred Holt and for the B.I.S.N. Company. Five generations of Scotts have been in the business, and since 1824 there has been associated with it the Greenock Foundry, where the engines for the steamers built in their yard have been constructed.

The China

Earlier in these notes I spoke of the cost to which the P. & O. Company had been put to settle the claim for the salvage of this ship. I should not omit to mention the difficulties which Messrs. Harland & Wolff encountered when they came to dry-dock the vessel for her permanent repairs. She could not—owing to the fact that so much of her bottom forward and amidships was gone and had been temporarily replaced for the voyage home by timber backed with concrete—let her down on the blocks for her whole length in the ordinary way. So another plan had to be evolved. Eventually the following highly successful method was adopted. Through the injured portions of the vessel great square baulks of timber were inserted below the decks, the vessel's side plating being cut to allow them to project on either side. To correspond to these, uprights of similar strength were set on the altar courses of the deck at the proper intervals. When the vessel was floated in and the water lowered, the tops of the uprights took the horizontals, and so bore the weight of the damaged portion instead of allowing it to rest on the temporary work below. The idea was successful enough, but the task of working out the positions of the timbers and of placing the ship herself exactly in the right spot must have been a very anxious one.

CROSBY INDICATORS.

THE Crosby Steam Indicator has for some years past given engineers most satisfactory results, but the makers, not content to rest on their laurels, have found room for improvements.

The first is the improved design of bracket (Fig. 1), which serves as a fulcrum for the pencil-lever, thus giving increased rigidity. Then the pencil-lever has been made of special section to combine lightness with great strength, &c., whilst the connecting link is heavier to resist sudden shocks without vibration.

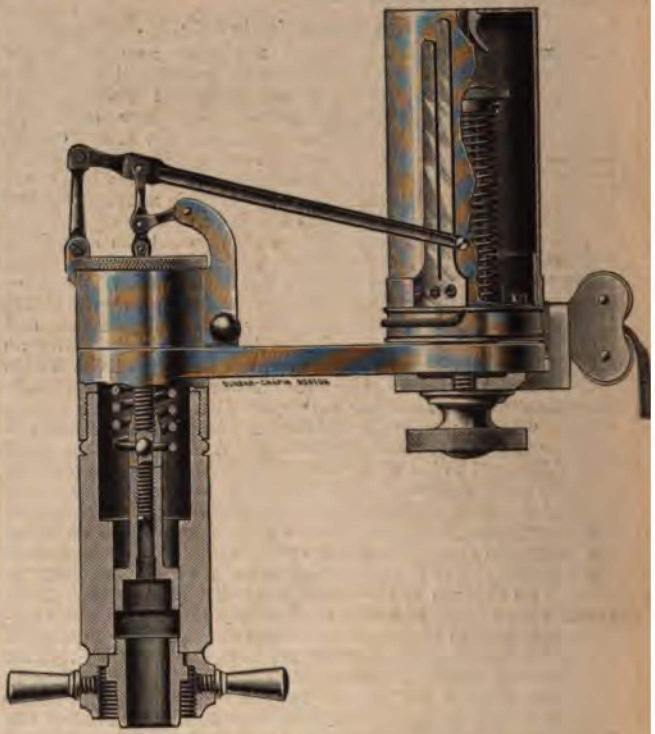

FIG. 1.

A new feature has been introduced to meet the trouble experienced in the testing of gas-engines when the pressure comes with a great and rapid rush on explosion of the charge. This has been overcome by a special design of cylinder shown in Fig. 2.

The cylinder is of extra length, and has two boxes; the upper one, to receive the piston used in the steam-engine indicator, being one-half a square inch in area; and the lower one, to receive the piston used in the gas-engine indicator shown on page 151, being one-quarter of a square inch in area. By replacing the smaller piston by the larger one, this special indicator can be used for steam-engine work, quite as well as the ordinary steam-engine indicator. The piston is made of hardened tool steel, and has its upper part, which connects it to the piston rod, lengthened to carry the piston entirely below the larger box and into its own cylinder.

There is also manufactured by the firm an hydraulic indicator for hydraulic pumps working against light pressure leads. The pencil motion is of the same heavy pattern as the gas-engine indicator, and it has also a post (shown in Fig. 2), bearing lightly against the pencil arm to keep the pencil point from being thrown away from the card by any sudden shocks.

The piston is made one-fortieth of a square inch in area, and fitted in a cylinder at the bottom of the instrument. A by-pass is made in the metal, at the side of the small cylinder, by which the pressure may be transmitted to the larger cylinder above, where the pressures to be received are not too high for the spring. This by-pass is closed tightly by the cock, shown in the cut above, where the small piston is used.

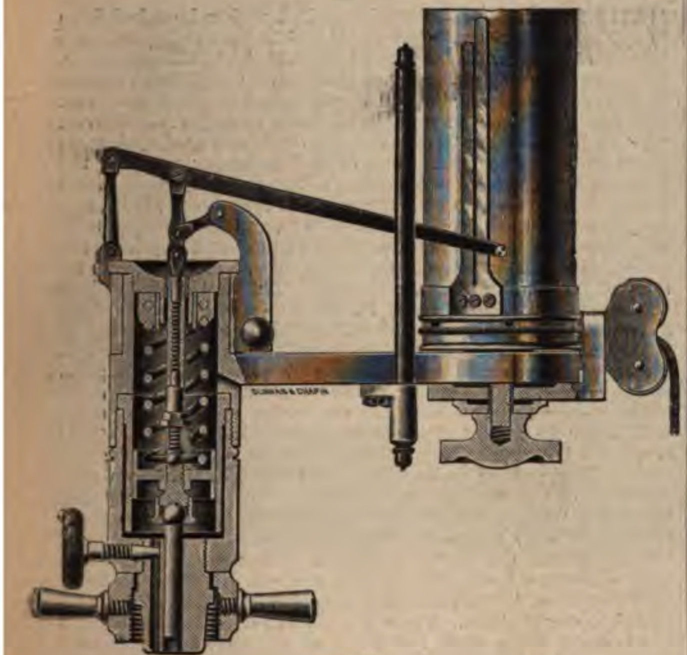

FIG. 2.

When taking the diagrams from the different cylinders of the engines of a torpedo-boat destroyer, it is difficult to obtain simultaneous diagrams, since that depends on three or four operators. Mr. Sargent has invented a device which will enable simultaneous diagrams to be taken by closing an electric circuit.

Fig. 3 shows the indicator with a Sargent electrical attachment. It consists of an electro-magnet, supported by a bracket. To the same bracket are attached binding-posts. The armature is opposite the magnet, and held by a spiral spring in the centre of the coil, the tension of which is adjustable by means of the screw at the back of the magnet. A hook is free to engage with a screw-eye inserted in the arm. The circuit-closer consists of a bracket with a tubular projection fastened to it, which contains the circuit-closing mechanism. It is attached to the indicator-plate by the thumb-screw in precisely the same way that the magnets are to the other indicators, and is electrically connected in the same manner through the binding-posts.

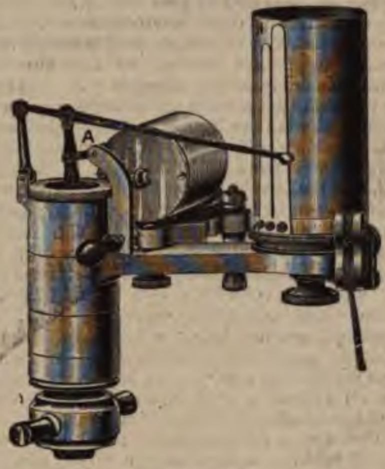

FIG. 3.

Suppose it is required to take simultaneous diagrams from a compound engine. Connect the battery, having all the magnets and the circuit-closer in series. Place the paper in the drum, and bring the pencil-arm into such a position as will allow the latch to drop into the screw-eye. Connect the drum motions, open the indicator-cocks, and close the circuit; instantly all the pencils will be brought against the papers, and will remain there as long as the circuit is kept closed. To put on newpapers; disengage the arm motions, lift the latch, and swing the pencil-arm out of the way.

WEIR'S FEED PUMPS.

TEN years ago it was only the largest-power steamers that were fitted with separate feed pumps, and up till a few years ago they were considered an innovation of doubtful success, but the advent of greater boiler pressure and faster running engines turned the scale in favour of the separate pump. The previous practice of fitting feed pumps on the marine engine had many disadvantages, amongst which the necessity of admitting a considerable quantity of air with the water to ensure silent working was one of the very worst points. The extra tear and wear, and the difficulty of keeping the glands tightly packed, of the marine engine feed pumps have gradually forced them out of the field in favour of the separate pump; and it is now the exception for marine engines to be fed direct from the engine in the old way.

Many kinds of pumps have been fitted as separate feeds, but the crank shaft, duplex, and outside packed pump have gradually given way before the Weir direct-acting type, and now it is rare to meet a marine engineer who has not been a shipmate with Weir pumps. So universally have they been adopted that it is hardly possible to go on board a mail steamer belonging to this or any other country that has not these important auxiliaries fitted in conjunction with the equally well-known feed-water heater.

The advent of the water-tube boiler, with its much higher pressure and carrying such a small quantity of water that a feed pump becomes a doubly important adjunct, has also been the means of opening a very extensive field for the Weir pump; and, although different kinds of pumps have been tried with indifferent success, it is now almost exclusively the Weir pump that it is fitted on this class of work.

There must be some strong reason for such a unanimous opinion amongst engineers, because they as a rule are men with diverse views, and almost in every other branch of engineering they have their hobbies and fancies that they adhere to.

The other evening, at a discussion in the Institute of Marine Engineers, one point was raised regarding the Weir pump that might have an important bearing on the question, viz., the steam consumption of auxiliary engines. In this respect it was astonishing to learn that a mechanical efficiency of over 90 per cent. was attained with the pump, and at a very low steam consumption; it was then stated that 22 lbs. of coal per hour would be sufficient to feed boilers of 1,440 H.P. This seems marvellously small, and had the statement not come from Mr. Weir's representative, it might have been questioned; but since then we have had an opportunity of seeing the results of some tests very recently carried out in presence of a third party, which we have no reason to doubt, and the statement was amply confirmed. When we compare this result with the performances of some other auxiliaries on board ship, it is much to their disadvantage, and we think owners would be justified in calling for guarantees and tests of their auxiliary engines.

But we are digressing, and coming to the reason for the Weir pump being so extensively used as a boiler feeder, we have evidently one good reason in the steam consumption. It must be obvious to all that a pump using twice the steam to drive it will only pump half the water into the boiler per lb. of steam used, and would instantly leave the field clear for the most economical motor. But in feed pumps there are other things to be considered as well as steam consumption; for instance, in the water-tube boiler feeding one previously mentioned, reliability is surely an important factor.

In a water-tube boiler the quantity of water carried is seldom more than a ton, whereas in the cylindrical type we get 35, 40, or 50 tons; and, following out this reasoning, it will be seen that it is a most important point with the water-tube boiler to have a reliable pump. In many cases the evaporation is so great that, should anything go wrong with the constant supply of feed, the boiler would be empty in four or five minutes. But the Weir pump is almost exclusively used for water-tube boiler feeding, and no further proof of its reliability is required. In no case can we remember a water-tube boiler coming to grief through shortness of water due to the pump having broken down.

Not very long ago some writers in one of the electrical journals gave the results of their test of boiler-feed pumps under their own control. The results are interesting, by way of comparison, although they show that electrical engineers in the country do not hold a very close communion with the marine engineer. One writer relates his experience of four pumps, the first of which delivers 31·3 lbs. of water per lb. of steam used against a head of 40 ft. No. 2 pump delivers 18·3 lbs. of water per lb. of steam under similar conditions. No. 3 pump delivers 1·77 lb. of water per lb. of steam when feeding boilers at a pressure of 160 lbs., and No. 4 pump delivers ·957 lb. of water per lb. of steam under the same conditions as No. 3; whilst the Weir pump, feeding a boiler with 160 lbs. pressure, could deliver almost 85 lbs. of water per lb. of steam.

The workmanship and materials of the Weir pump are another consideration, being most excellent. The makers have laid down large works specially adapted for the manufacture of this kind of work, and run their own iron and brass foundry.

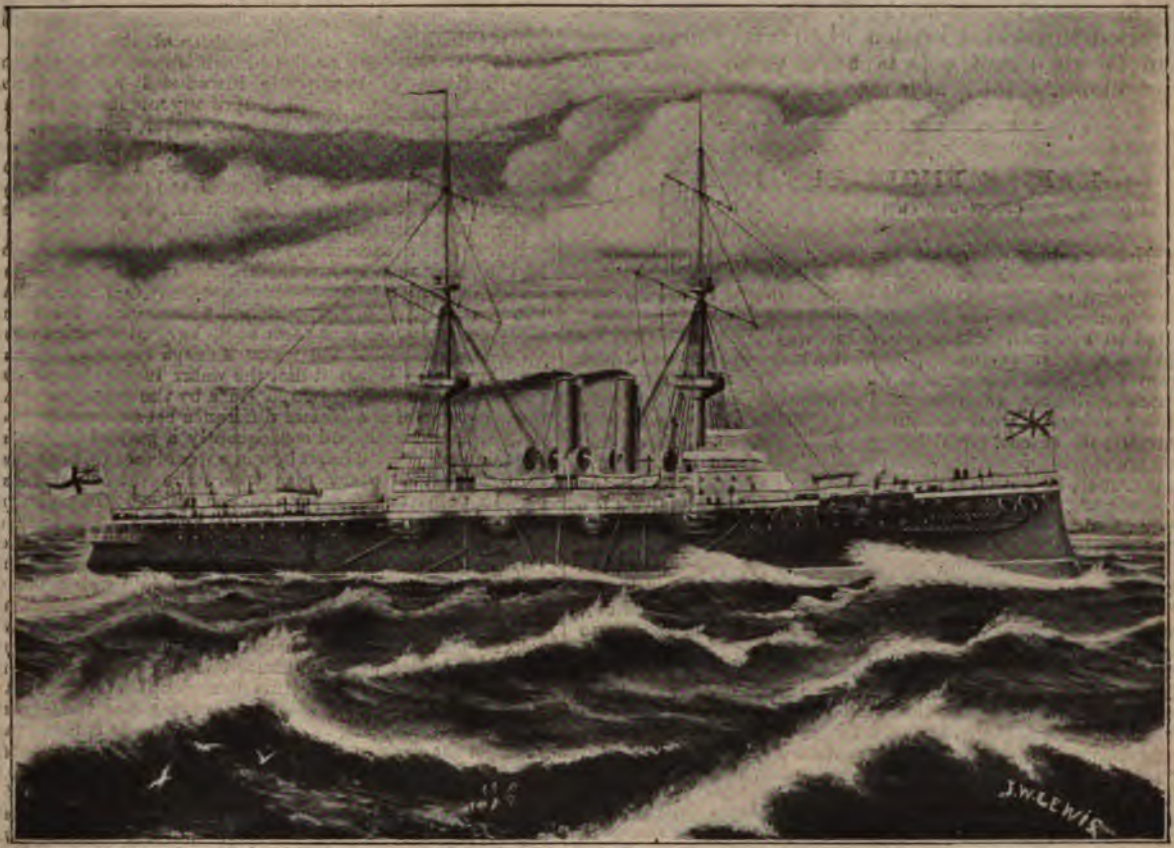
The Weir pump is arranged in several systems. The main engine feed pumps have a branch from the main feed pipe to the feed heater. They discharge directly to this from the hot well. Weir's pumps draw from the heater and discharge to the boiler. The pumps are independent of each other; but one pump is fitted with a cast-iron liner and steel-piston rod, whilst the other, which has a sea suction, is fitted with a gun-metal liner, bucket, and cold-rolled manganese-bronze rod. The iron-lined pump is used when the heater is in use, and the brass-lined pump when drawing from the sea. One pump is sufficient to deal with the entire feed-water, and the other may be a stand-by. The speed of the pump is controlled by the float in the heater. The exhaust is fitted to the atmosphere and low-pressure casing.

Another arrangement is to have a pair of pumps with a float tank and feed-water heater. In this case no pumps are required on the main engines. A feed tank with automatic float gear is placed under the pumps, and the air pump discharges into this. One of the feed pumps draws from the tank and discharges into the feed-heater, the other draws from the feed-heater and discharges to the boiler; the first is regulated by the float in the tank, the second by the float in the heater. It is so arranged that in case of accident either pump can feed direct to the boilers from the float tank without using the feed-heater. Sometimes a third pump acts as a stand-by.

When the speed of the engines is high, still another arrangement is in use. In this case there are no feed pumps in the main engines, only a pair of pumps and a float tank are used to deal with the feed-water. The water is returned to the boilers independent of the main engines; each pump is capable of doing all the work. The water is discharged by the air pump to the float tank, and the pump draws from the tank and discharges into the boilers. These pumps are fitted with gun-metal liners and cold-rolled manganese-bronze rods. A heater is not used, but the feed-water may be heated by leading steam from the high-pressure receiver and the exhaust of the pumps and other auxiliaries to the float tank. The water may also be heated by placing a surface feed-heater between the pumps and boilers, making it form a part of the main feed pipe.

H.M.S. "VENGEANCE."

THIS British line-of-battle ship, which will be launched from Messrs. Vickers, Sons & Maxim's Naval Construction Works at Barrow on the 25th of July, is of the *Canopus* class. The accompanying picture photograph, from a painting, depicts H.M.S. *Vengeance* as she will appear when completed for sea. She has 1 ft. 6 in. less draught of water than the *Magnificent*, which will enable her to pass through the Suez Canal, and, more important still, to enter some of the shallower ports of the Empire, her displacement being 12,950 tons, as against 14,900 for the *Magnificent*. The length of the *Vengeance* is 390 ft., and the beam 74 ft., whilst the depth is 43 ft. and the draught 26 ft. The broadside is of 6 in. armour, the length and depth of the belting being the same as in the *Magnificent*. The armour is an alloy of nickel, chromium, and steel. The trial plates of this thickness — 8 ft. long by 6 ft. wide — stood 6 shots fired at a distance of only some 6 ft. with a muzzle energy of 2,500 tons, and yet the 100-lb. projectiles were smashed to pieces, whilst no crack was visible on the plate. The 6-in. plate seems adequate protection in view of the ballistic qualities of modern guns and the fact that the future naval engagements will likely be fought at a range of fully half a mile. This armour will certainly keep out explosive shells. The protective deck is thinner than in the *Magnificent* class, but the gun protection is equally satisfactory, a feature in our modern ships for which Sir William White deserves compliment. The armament of the *Vengeance* is the same as in the other fourteen ships of the *Magnificent* and *Canopus* classes. There are two barbettes with armoured hoods, one forward and one aft, and each is to have two 12 in. 45-ton breechloading guns, so mounted as to be loaded in any position. There are to be twelve 6 in. 100-lb. guns of the quick-firing type, two firing ahead and two astern and three on either broadside, but the forward and aft pair of broadside guns can also fire in line with the keel, so that two are bow and two stern chasers; whilst for similar use there are two 12-lb. quick-firers forward and two aft, the other eight being on the broadside. The *Magnificents* have an extra pair of 12-pounders in the bow fire, but this is the only difference. The new ships will have four submerged tubes for the discharge of torpedoes; those above water have been found dangerous owing to the possibility of the projectile striking them when a torpedo with its gunpowder charge is lying in the tube ready to be discharged at the enemy. The engines are to be of the triple-expansion type, with cylinders 30 in., 49 in., and 80 in. diameter respectively by 4 ft. 3 in. stroke. These are to run at 110 revolutions, with 13,500 I.H.P. This, it is anticipated, will give a speed of 18½ knots, whereas the vessels of the *Magnificent*-class have a speed of 17½ knots, although some of them on their trials slightly exceeded this. This gain is in part due to the reduced draught and increased area, and it is the more certain of realisation as forced blast is not resorted to, as in the *Magnificents*. The boilers are of the Belleville type, with economisers added. There will be twenty such boilers, the total grate area being 1,050 square feet, whilst the heating surface is close upon 33,800 square feet. The total weight of machinery is 1,290 tons, so that the power is equal to 10½ I.H.P. per ton of machinery; whilst with natural draught the *Magnificents* and *Renowns* only give 8 I.H P., and even with forced draught 9·6 I.H.P. In other words, for only 12,000 I.H.P. the weight of machinery in the other ships was 1,300 tons, so that with less weight the new ships have 500 I.H.P. more, giving an addition of three-quarters of a mile to the speed per hour. This is a moderate estimate of the advantage accruing from the adoption of Sir Albert Durston. It may be added that specially onerous conditions are given in connection with the boiler tubes. If a relatively small percentage of any group of tubes submitted for trial prove unsound, the whole group is liable to be condemned.



H.M.S. VENGEANCE.

It is interesting to note in connection with the *Vengeance* that she is the first battleship ever built and thoroughly completed by one firm, because Vickers, Sons & Maxim have not only built the ship and constructed her engines and auxiliary machinery, but they have the order to mount her with their own guns, and they had already supplied their own armour plates for her construction. This is an undoubtedly big achievement, but in course of time still further developments will be made at the Barrow shipyard with the view of enabling the firm to establish other departments of their works, so as to be able to do all the work in connection with shipbuilding, engineering, boiler-making, gun manufacture, gun mountings, armour plates, &c., in their own yard. The order for the *Vengeance* was given in July, 1897. Her hull is very nearly completed, and her engines are ready to be lifted into the ship as soon as she is launched.

Steam Syrens.—We are informed that the Admiralty have instructed Messrs. Sydney Smith & Sons, Basford Brass Works, Nottingham, to fit up on board H.M. warships *Arrogant* and *Jupiter* the largest type of their patent steam syrens, which are to be operated by geared appliances. These syrens have long been used in the mercantile and naval service, so that their efficiency and merits have long been established.

SPECIAL MACHINE TOOL FOR SHIPBUILDING REQUIREMENTS.

MESSRS. CUNLIFFE & CROOM, Limited, of the Broughton Ironworks, Manchester, have recently completed for a large shipbuilding firm on the Mersey a specially designed duplex vertical milling machine, of which we give a page plate illustration. This machine is so constructed that it can be operated either as one tool for heavy, or as two separate tools for lighter operations. The bed is of strong box pattern, 15 ft. long, with four wide bearing surfaces to support the tables, which are each 10 ft. long and 3 ft. 6 in. wide, and provided with variable self-acting feed motion in either direction, and a quick return by power both ways. The milling headstocks and tables can be run separately as two independent machines, or the tables may be coupled by means of an endless chain, which is easily detachable, and one or both heads put in operation. The two headstocks, which are mounted on a strong cross slide, are provided with independent driving and feed motion horizontally and also quick hand adjustment in both motions. When the cutters are employed on side milling or profiling, the bottom end of the mandrel is received and supported by means of a circular support, and when it is desired to mill brass or gun metal, or the tool is only required for light cuts in wrought iron or steel, the back gear can be thrown out of action. Two portable circular tables are provided—one on each of the long tables—with self-acting feed, when circular milling, such as round the ends of connecting rods and similar work, requires finishing. All the motions for starting, stopping, and reversing the feed and the quick-return motion, are within easy reach of the attendant standing at either side of the machine. A pump and cistern are provided to keep a constant supply of lubricating fluid on the cutters when working. The machine is constructed to resist vibration when taking heavy cuts, and it will admit objects 8 ft. wide between the uprights. All the gear is machine cut.

MARINE ENGINEERS' NOTES.

(From our own Correspondent.)

AN interesting discussion has taken place at the Institute of Marine Engineers' on the paper read by Mr. McArthur on the comparative performance of two steamers. The author gave one steamer as having been built and fitted to contract, while the other was built to sell. He gave a number of figures, and the inference to be drawn from the figures was that it did not pay to work a steamer which had been got cheap. For example, one of the most telling things against the steamer built to sell was that it used 1·7 lb. of coal per I.H.P. per hour and ·00488 lb. of coal per ton carried per mile, whilst the contract-built steamer used only 1·23 lb. of coal per I.H.P. per hour and ·00316 lb. per ton carried per mile. The author did not separate in his analysis the performances of the boilers and compare them, or of the engines, which were quite different in dimensions and performances. The pumps were different, and so were the propellers; and the author did not give the differences of the performances due to these. Then the dimensions of the ships were quite different, and the tons were not given; and the weather, wind, and course were not given in either case. Mr. Adamson, in the discussion that followed, gave figures for the performances of steamers. In some cases the figures given for the same steamer over the same course differed quite as much as the two different steamers given by Mr. McArthur. The only factors which caused the difference in the figures given for the same steamer by Mr. Adamson were weather, wind, and current. Yet the consumption with a vessel of similar dimensions to those given in the paper per ton of displacement was on one occasion ·0461, and on another occasion ·0643. This is quite as great a difference for the same steamer over the same course as exists between the contract-built steamer and the steamer built to sell, given by Mr. McArthur. The conclusion, therefore, to be drawn is, that the wind, weather, and sea may account for the difference given in the performances of the two steamers. Though, therefore, the comparison of the performances is of little value, the figures and statement given are of much value to the members. For example, the question of the steam used by the pumps was raised. From the paper on auxiliary machinery, and even this, and also the paper on the trials of the *Minneapolis*, the only conclusion which could be drawn as to the performances of pumps was that between 90 and 250 lbs. of steam were required by pumps per pump H.P. The article on Weir's pumps, in another column of this issue, will show what can be done in this respect. Another question raised was the size of grate surface compared with heating surface, the rates given being 1 to 52. In some cases it goes as low as 1 to 25. With regard to the grate, it should be remembered that the experiments conducted by Mr. D. K. Clarke showed that within certain limits the smaller the grate area the better. The excellence of the results obtained by Mr. Mumford by his water-tube boilers is in no small degree due to the small area of his grate, and the high efficiency of locomotive boilers is due greatly to a deep fire and strong draught. There are other features which enter into the excellence of the work done by the locomotive boiler, but these are some of them. Mr. Bruce brought forward the question of draught and the supply of air to the furnaces. A supply of too *much air*, which causes the hot gases to heat up the superfluous air and send it up the chimney as waste heat, should be guarded against. Excess of air one must have, but as little excess as possible should be aimed at. It is curious that the locomotive, which has the strongest draught, should use the least air of combustion, and at the same time have the highest efficiency as to complete combustion.

The fine weather has caused the younger members of the institute to go in for lighter amusements than the discussion of papers or the attendance at lectures by Mr. Hawthorne. A tennis club has been started, the court being the lawn at the back of the institute premises. Mr. W. J. Taylor is president, Mr. R. Leslie vice-president, the captain is Mr. W. E. Farenden, and secretary Mr. H. H. Mather. The name of the club is the Institute of Marine Engineers Tennis Club. The qualification for membership is—(*a*) Membership of the institute in any grade; (*b*) Relations (ladies or gentlemen) of any member of the institute of any grade introduced by that member; (*c*) Friends (ladies or gentlemen) of any member of the institute of any grade introduced by that member, and proposed by one other member of the club. All members of the club to sign the visitors' book in the lobby on arrival. The fee for the season is 5s. per member. Any member of the institute of any grade can take part in a set at a charge of 3d. per person per set if the court is not fully occupied.

There was an exceedingly animated discussion at the institute on the paper read by Mr. G. Halliday on the "Heat-Absorption Power of Water." Mr. Macfarlane Gray and Mr. Williams, of the Board of Trade, took part in the discussion. Mr. Macfarlane Gray could not see that there could be a falling-off of absorption when the velocity of the water through the tube rose above a certain value. When it did, the water inside the tube was not raised quite so high in temperature by the steam outside, consequently there was a greater difference between the temperature outside than inside, and consequently a greater transmission of heat per minute. That is how one would reason, but experiment showed that in every case where the velocity rose above a certain point the transmission per minute fell. The point of maximum absorption varies. It appears to depend on the quantity of heat supplied. If the quantity of heat is great, the velocity of the water when the maximum transmission takes place is greater. It appears as if a certain wetness of surface was necessary when the maximum transmission takes place. When this wetness of surface has been reached, and the velocity goes beyond this point, there is loss. This is possibly due to the heat being conducted to the inside of the moving column of water, and the time given for this being shorter.

Mr. Leslie writes from Calcutta, saying that the formation of a new branch is being talked about there. It is being talked of amongst the engineers of the British India Company's steamers, and someone has offered to be secretary of the affair *pro tem*.

Mr. Adamson has written a long letter to the Board of Trade on the question of the new regulation for the examinations for engineers. The notable improvements in the drafted rules of the Board are those which define the necessary workshop service, and No. 9 rule shows that the examiner can request a definite statement as to the sea service of candidates. Article 22 is referred to by Mr. Adamson, and the gist of it given as follows:—(*a*) The five years' workshop service, on which the Board will now insist as a minimum before a candidate presents himself for a second-class certificate; (*b*) The definite time that a candidate must serve in special departments of the works, in order to qualify him, is specified distinctly. The time allowance for candidates attending a technical school is considered to be too much, and by resolution the institute requests that three years in a technical school should count as one in the workshop.

Then the question of a third-grade certificate is raised, although it is not referred to in the draft submitted by the Board of Trade. The institute considers that something ought to be done to furnish the junior members of the merchant fleets with a certificate of competency. But is not this foreshadowed in the suggestion in the draft with regard to the powers of the superintendents of the fleets? These superintendents have in certain cases to furnish certificates of competency, which are to be examined by the officers of the Board of Trade, and in a way these certificates of the superintendents may be looked at as third-grade certificates. The superintendents, being conscientious engineers, would not in any case furnish any young engineer with a certificate if he were not competent, and thus those certificates submitted to the officers of the Board of Trade are really third-grade certificates. What the institute's duty is in the matter is very plain. It is the duty of the institute to enhance the value of these certificates, but to use their influence with the superintendents to increase the value of the certificates until they stand as a recognised entity before the country. How, then, can this be done? By attaching a definite course of instruction both in the theory and practice in the construction of marine machinery. It is for the council of the institute to suggest a course and prescribe rules, to be submitted to the superintendents of the merchant fleets.

NAVAL MATTERS—PAST AND PROSPECTIVE.

(From our own Correspondents at home and abroad.)

The Hydrographer's Report.

A MOST interesting report on naval surveys has just been issued by Admiral Wharton, the Hydrographer to the Admiralty. The number of officers and men employed in the surveying branch of the Navy, according to this report, is only 714, of which 75 are officers, and the work they have accomplished is astonishing. Although these surveying vessels have been at work for so many years, and have done so much each year, the amount of work to be got through seems to increase rather than decrease with every succeeding twelvemonth. Admiral Wharton states that 11 vessels were employed in coast and other surveys, during 1898 757 miles of coast line were charted, and soundings taken over an area of upwards of 10,000 square miles. Reports have been sent in from all parts of the world, but particular interest attaches to the report of the work done by the *Waterwitch* in Chinese waters. The crew of this vessel surveyed Wei-Hai-Wei Harbour in the summer of last year, and also did excellent work on the island of Leu Kung Tau, and in and about the harbour of Tinghai. The *Stork*, which was at work in the Red Sea, and the *Penguin*, in the South Pacific, made some interesting discoveries. Commander Gedge, of the first-named ship, found that there is one permanent surface current setting through the Straits of Babelmandeb, and another setting in the contrary direction below the depth of 75 fathoms. Captain Field, of the *Penguin*, took some exceptionally deep soundings in the South Pacific, including one of 4,762 fathoms in the vicinity of the Tonga Islands. Metis Island, Captain Field reports, has vanished altogether. Other vessels reported the discovery of a great many new shoals and rocks in the track of shipping. Altogether Admiral Wharton's report may be recommended as excellent reading matter, being both entertaining and instructive.

A Foundry at Sea.

The work done by H.M.S *Vulcan*, now stationed in the Mediterranean, gave to the Navy Department of the United States the idea of building a similar vessel which could do all the repairs, or a great part of them, of a squadron at sea. Therefore the department set to work, and had designed for them such a vessel, and when she was built and ready for sea gave her the name of our own torpedo depot ship in the Mediterranean. A most interesting article on the work done by this ship, especially whilst attached to Admiral Sampson's fleet off Cuba, appeared in last month's *Engineering Magazine*. The account is written by Chief Engineer Sims and Professor W. S. Aldrich, both of whom had charge of the fitting-out of the ship and of her work while under Admiral Sampson. These gentlemen assert that a foundry at sea had not been heard of before the cruise of the *Vulcan*, and go on to say that whatever other kinds of naval repair work had been executed heretofore on board ship, that of making large brass and iron castings had not been attempted. In her facilities for this new line of work the *Vulcan* stands pre-eminent and alone. That the unique equipment for foundry work was successful is more than shown by the fact that thousands of pounds of iron and brass castings were made and finished for the ships of the fleet. The brass furnaces were kept in almost constant service, sometimes running off two heats a day, and making it necessary to carry the work far into the night. In iron castings not more than one heat was run off in a day, and that usually about three o'clock in the afternoon, for, after filling the moulds and dropping bottom, it was practically impossible to do much more in that part of the ship until the next morning. We have no ship fitted in this manner in the British Navy.

Portsmouth Dockyard.

The Channel Squadron and part of the Reserve, which now lies at this yard, are being prepared to take part in the manœuvres, which commence in about three weeks' time. The *Latona*, *Naiad*, and *Sybille* have been brought forward for mobilisation, and the *Terrible* is also to be prepared, to be ready, if possible, to take part in the manœuvres, as well as the *Andromeda*, *Europa*, *St. George*, and *Gladiator*. The ratings in reserve are 3,800 in the depot, including bluejackets, mechanics, stokers, and marines, 1,500 bluejackets at Whale Island undergoing instruction, and 890 men going through the *Vernon*. The Channel Squadron is supposed to be ready for sea by the 4th of this month, but, unless a great many defects are left unattended to, the order to this effect cannot be carried out. Mechanics are said to be very short in the squadron, and great difficulty is being experienced in getting men to fill the vacancies. Among the ships which have recently arrived here from abroad is the *Narcissus*, which was paid off on the 22nd of last month, after she had been dismantled. The *Fox* has also returned from the Cape Station, and the *Pallas*, which has just returned home, is to be prepared for another three years' commission abroad. She has already served two commissions on a foreign station. The *Intrepid* has also arrived from the North American and West Indies Station, where she has served a somewhat eventful commission. There is some talk of the *Barham* being employed as a Royal Naval Reserve drill ship. She has successfully passed through her steam trials, and although she is fitted with water-tube boilers and modern guns, the fact that her bunkers are only capable of holding 225 tons of coal goes to show that she is not of much use except for employment nearer home. As regards the *London*, work on her steadily continues, and most of the plates of her upper deck have now been placed in position. Early last month about one hundred journalists from the press gallery of the House of Commons visited the yard, so that in future they could have a better understanding of naval subjects as they came up for discussion in the House. The Navy League also visited the Dockyard and Whale Island a week ago, when the Earls of Drogheda and Denbigh were among the visitors. It may be officially mentioned here that the *Seagull*, the only vessel in the Navy provided with the Niclausse type of water-tube boiler, carried out several steam trials in a very satisfactory manner. She is to have five trips of 1,000 miles each, at varying rates of speed, as soon as she can be prepared for commission.

Old Names for New Warships.

No fault can be found with the names chosen for the four new armoured cruisers which are about to be commenced, in accordance with last year's naval programme. Two of these vessels are to be built at Portsmouth and Pembroke respectively, the vessel to be laid down at the first-named yard being named the *Kent*, and that to be laid down at Pembroke to be named the *Essex*. Both names are closely connected with the old navy, for it is on record that a vessel of the name of *Kent* captured the Spanish line-of-battleship *Princesa*, and the name has been borne by various vessels which have fought in all sorts of actions from the battle of Malaga onwards. A vessel of the name of *Essex* took part in the battle of Malaga, and a vessel of this name fought at Quiberon Bay. The other two cruisers are to be built by the London & Glasgow Engineering & Shipbuilding Co. and the Fairfield Shipbuilding Co., and are to be named the *Monmouth* and *Bedford* respectively. The name *Monmouth* recalls the time when the Dutch came up the Medway and burnt our warships, but vessels of the same name took part in the victories at Barfleur, Vigo Bay, and the capture of Gibraltar. It was a *Monmouth* also that captured the *Foudroyant* in 1758. A *Bedford* fought at Malaga in 1704, and in the West Indies and on the American coast during the last century. All four vessels will be of the same length as the *Cressy* class, and their breadth will only be 66 ft., and they will displace 9,800 tons to the *Cressy's* 12,000. The *Kent* is to steam 23 knots, and the other vessels 22. The new cruisers will have two protective decks, of which the lower will have a considerable curve, extending the whole length of the ship. A transverse vertical armoured bulkhead crosses the ship abaft the engine-room, and the 4 in. side armour is to extend from the bulkhead to the bows. The space between the two armour decks forms the reserve bunkers. The vessels will be armed with 14 6-in. guns, 10 12-pounders, and smaller weapons. Their coal capacity is to be 800 tons as a normal supply, with a total capacity of 1,600 tons.

The French and English Construction Records.

The proposed launch of the French battleship *Suffren*, on the 25th of this month, reminds one of the claim made by the French builders that they have beaten the record for speedy warship construction. The *Suffren* was laid down in January last, and, if she is launched at the time stated, will have been on the stocks only six months and twenty days. That this is a hollow claim must be seen, as the launch of a vessel is only an incident of her construction, and does not alter the length of time taken to complete the ship if she is launched six months after she was commenced, or sixteen months afterwards. The real test is the number of tons built into the ship at the time of the launch. A telegram from France recently said that the rapidity of construction of British warships had already been beaten in the case of the *Iena*, constructed in seven-and-a-half months. The *Iena* is a battleship, displacing 12,050 tons, and was launched in about eight months from laying down with the weight of 3,580 tons. Against this it may be mentioned that the *Ocean* was launched at the end of sixteen months, and weighed at that time nearly 8,000 tons, and the *Implacable*, launched at the end of eight months, weighed 5,000 tons. The *Formidable*, which had been on the slip about the same time, when launched weighed 4,500 tons. And against the six months and twenty days which the *Suffren* will have been on the stocks, if she takes the water on the 25th, it may be mentioned that if the *Bulwark* takes the water at Devonport at the date fixed, three first-class battleships will have been launched from the same slip within 18 months. It will be a surprise if the *Suffren* weighs more than 4,000 tons when launched.

Devonport Dockyard.

There has been a great deal of work done lately at this yard in connection with the mobilising of the ships which are to take part in the Naval Manœuvres. There are quite a number of cruisers and torpedo vessels in the Fleet Reserve here available for commissioning, in addition to the ships of the Channel and Reserve squadrons. The cruisers *Juno*, *Æolus*, *Sirius*, *Thames*, *Cambrian*, *Charybdis*, *Pique*, and *Hermes*, the gunboat *Dwarf*, the torpedo-boat destroyers *Lynx*, *Bat*, *Thrasher*, *Locust*, *Osprey*, *Wolf*, *Leven*, and *Gipsy*; and the torpedo boats 45, 52, 53, 55, 57, 58, and 80 are all practically ready for sea. The battleships *Collingwood*, *Thunderer*, *Nile*, *Benbow*, and *Colossus*, and the cruiser *Melampus*, which are in commission in the western command as port guardships, have been lately docked and refitted. The *Magnificent*, *Arrogant*, *Furious*, *Niobe*, and *Pelorus* have all been docked and refitted prior to mobilisation. There are some 3,000 men in the Royal Naval Barracks here, and a good number going through the gunnery and torpedo courses on the *Cambridge* and *Defiance*. Great progress is being made with the *Bulwark*, which has now been in hand a little over three months and the *Implacable* and *Ocean* battleships, the *Hermes* and *Highflyer* cruisers, the *Dwarf* gunboat, and the *Gipsy*, *Leven* and *Wolf* torpedo-boat destroyers are all receiving a good deal of attention. The delay which has been experienced lately in the completion of the *Implacable* would not have happened had the ship's armour been delivered from the contractors at the proper time. The Navy League visited this dockyard a week or so back, and were shown over the workshops and smitheries and various vessels in the docks and basins. It will interest many to know that Sir William White is to visit Devonport this month, and is to be presented with the freedom of the City. He is to open some new technical schools.

The Coal Used by the Victorian Naval Defence.

A most interesting report on the coal used by the torpedo-boats of the Victorian Naval Defence Force was recently sent in to the secretary of this organisation, and has just appeared in print. The report is made out by Lieutenant F. Tickell, in command of the turret ship *Cerberus*, and deals with the results attained when the torpedo-boats of the colonial defence, the *Countess of Hopetoun* and her sisters, were using the Gippsland coal supplied by the Victorian Government. Lieutenant Tickell considers that the coal is unfit for use during active service on account of the dense smoke and flame which pours from the funnels on the fans being used to create a forced draught. Not only would this expose the boat to instant discovery, but he asserts that when using this coal the boats cannot maintain the maximum of speed after even a few minutes, whilst on a run of a few miles not more than two-quarters speed can be kept up. A torpedo-boat using this coal could not evade detection at night, and as the value of these boats depends upon their not being observed, other coal—or means of burning the Gippsland coal—will have to be resorted to. Lieutenant Tickell suggests that some of the best Welsh coal be imported to Victoria for the use of the torpedo-boats whilst on active service. But before this extreme step is resorted to, a mixture will probably be tried of Victorian and New South Wales coal. Of course it may not be the coal which causes the smoke and flame as much as bad combustion, but this question ought to be enquired into before the expense of taking coals from Wales to Victoria is incurred.

Building up the German Navy.

The launch of the new German battleship *Kaiser Wilhelm der Grosse* has once more directed attention to the efforts which are being made by Germany to build up a fleet which shall be equal to at least one of her rivals on the sea, France or Russia. The German Emperor, as usual, made a speech which was of great interest to report on the occasion. The *Kaiser Wilhelm der Grosse* is 383 ft. in length, with a beam of 68 ft., a mean draught of 26 ft., and a displacement of 11,081 tons. Her armament consists of four 10 in. guns in revolving turrets, twelve 6 in. quick-firing guns in armoured casemates, six 6 in. quick-firing guns in revolving turrets, twelve 3·4 in. quick-firing guns, twelve 1·34 in. and twelve machine guns. The torpedo armament is to consist of one 21 in. submerged bow tube, four 18 in. submerged broadside tubes, and one 18 in. above-water stern tube. The vessel is fitted with three triple-expansion engines in watertight compartments, capable of developing 13,000 H.P., and calculated to produce a speed of 18 knots. The normal coal-carrying capacity is 650 tons, which can be increased to 1,000 tons. The protection consists of an armour belt 6 ft. 8 in. in width, with a thickness of from 6 in. to 12 in. along the forward four-fifths of the vessel. The stern section is, for the sake of lightness, only protected by a 3 in. curved armour deck. Elsewhere the armour deck is only 2½ in. thick, and rests on the upper edge of the armour belt. The time given for the German naval manœuvres this year is from the middle of August to the middle of September, and the following is the force which will take part:—The battleships of the first squadron, the second squadron, which latter will be formed with armoured cruisers, the division of armoured gunboats of the reserve, two flotillas of torpedo-boats, the training ship *Blucher*, the small cruisers *Wacht*, *Hela*, *Blitz*, *Greif*, *Grille*, *Zieten*, and *Pelikan*.

Chatham Dockyard.

About the time these lines go to press the new cruiser *Pioneer* will have been floated out of dock, as the date fixed was the 28th ult. In connection with the launch of the *Venerable*, now building at this yard, it is rumoured that an effort will be made to have the launching ceremony performed by Princess Victoria of Schleswig-Holstein. The launch will take place about the end of September next. The *Venerable* is the longest and heaviest battleship ever constructed at this yard. She is to be hurried forward as much as possible, in order that a new battleship may be commenced on the slip she will vacate. As regards the two battleships *Goliath* and *Irresistible*, completing here, there is little to be said except that they are making good headway. The *Irresistible*, although not so far advanced as the *Goliath*, has a number of her armour-plates in position. The *Goliath*, on the other hand, has all her guns on board and in position, whilst she has received her engines and the 20 Belleville water-tube boilers allotted to her. It is expected that in a few days the preliminary trial of her engines will be completed. It is expected that they will produce 13,500 H.P., with a speed of 18½ knots under natural draught. They were supplied by Messrs. Penn. A new naval hospital is to be commenced about a couple of miles from this dockyard, as the accommodation at the Royal Naval Hospital is at present inadequate. The new building and site will cost about £300,000, and accommodation will be provided for 600 beds. Good progress is being made with the new naval barracks, but it is not expected that they will be ready for habitation for another two years. Every available hand was turned on to the ships of the Channel Squadron, which had been sent to this yard to have their defects made good. These were the *Repulse* and *Jupiter* battleships, and *Diadem*, *Furious*, and *Pactolus* cruisers. A great deal of extra work has been occasioned by the preparation of vessels which are to take part in the coming manœuvres.

A Royal Naval Tournament.

The suggestion has been made in several papers recently that a Royal Naval Tournament should be held in London each year in the same way as the Royal Military Tournament is held at Islington, the proceeds, of course, to go to naval charities. The only objection which the various writers cannot overcome with their pen is that a large enough piece of water cannot be obtained in London to admit of an adequate representation of the life and duties of our men-of-war's men. After all it does not seem such a great difficulty, for there are many large commons around London containing good-sized ponds which could be adapted to suit the needs of such an exhibition—the Long Pond, on Clapham Common, for instance. Taking the pond from the main road, a model of a battleship might be erected at the right-hand end, whilst at the left-hand end, leaving a good space of grass between the first row and the water, a great number of rows of seats could be erected, the whole place, of course, to be covered in. On the model of the battleship the seamen could give exhibitions of that part of their duties which would most interest the sightseers, whilst on the water boat-work could be shown, and demonstrations given on the grass of how a landing party comes ashore to fight. One of the writers remarks very truly that a man-of-war's man's drill is not merely confined to handling small guns ashore and exercises at cutlass and rifle drill :—"His activity at all sorts of work, swarming up a mast, lowering boats, serving big guns, and much else would, if exhibited at the Agricultural Hall, carry the town by storm. The sailors would show how torpedoes are launched from shipboard; submarine diving, and the method of saving life at sea by the rocket apparatus, would be a sure draw."

The Trials of the "Hermes."

Special interest attaches to the trials of the second-class cruiser *Hermes*. The *Hermes*, it will be remembered, belongs to the Estimates of 1896-97, together with her sisters the *Highflyer* and *Hyacinth*. The vessel displaces 5,000 tons, and, with 10,000 I.H.P. at natural draught, was intended to steam at 21·5 knots. She is fitted with two sets of four-cylinder triple-compound engines and Belleville boilers, of which there are eighteen. Her first run of thirty hours, with an I.H.P. of 2,099, showed a speed of 13·4 knots, the coal consumption per I.H.P. being 2·32 lbs. This was followed by two runs of twelve hours' duration with an I.H.P. of a little over 1,000, and a speed of 10·5 knots, the coal consumption varying from 2·31 lbs. to 2·61 lbs. The *Hermes* also underwent a second thirty hours' trial, on which a speed of 18·8 knots was obtained, with an I.H.P. of 7,712, the coal consumption being 1·57 lb. per I.H.P. per hour. On her eight hours' full-power trial a speed of 20·5 knots was obtained, with a total I.H.P. of 10,224. Although the Admiralty were satisfied with the speed and engine power attained on these occasions, the contractors were requested to repeat the thirty hours' trial at an I.H.P. of 2,000, as the coal consumption on the first occasion was in excess of that stipulated for in the conditions of contract. This trial took place, and the result was that the coal consumption worked out at 1·78 lb. per I.H.P. per hour, instead of 2·32 lbs. The remaining trials were all satisfactorily completed.

Sheerness Dockyard.

There is very little of importance to chronicle about this yard. The various vessels building and completing are all receiving their proper share of attention, as well as several vessels which have been sent here to have their defects made good, or to be refitted. The steam trials of the *Prometheus* have, as expected, proved successful in every way. She is fitted with the Thornycroft type of water-tube boiler, like her sister ships the *Proserpine* and *Perseus*. She first of all carried out a 30 hours' coal-consumption trial at 3,500 I.H.P. The vessel should have been delivered nearly twelve months ago, but the dispute in the engineering trade and various experiments with her safety valves have kept her in the contractors' hands until a few weeks back. The check which the *Pomone* met with during the progress of her commission trial proved to have been caused by nothing more than a leaky cylinder cover. Her sister ship the *Pyramus*, it is reported, passed through the whole of her contractors' trials in a successful manner. The sloops *Vestal* and *Sheerwater* will probably be floated out in November or December next, when the two new sloops mentioned in this year's Naval Estimates will be commenced. The *Basilisk*, which arrived home about three weeks ago, is to undergo an extensive refit without loss of time. This refit should be completed by the coming October The *Wye*, storeship, is now being prepared for her departure on the 14th inst. to Rio de Janeiro.

The Pay of Engineer Officers Abroad.

In a recent number of the *Globe*, the naval correspondent of that paper points out some extraordinary differences in the amount of pay received by the various engineer officers in charge of factories abroad. His figures are taken from the Navy Estimates. He points out, for example, that the inspector of machinery at Garden Island, Sydney, heads the list with £963 a year, and considers that, although this is not a sixpence too much, this officer is a very lucky man when it is remembered that he enjoys excellent society and a healthy climate. The inspector of machinery at Bermuda comes next, he having £831 per annum, unless, as is probable, the inspector of Hong Kong gets more pay than any of them. Next to him, however, is the chief engineer of Hong Kong Dockyard, who has a modest salary of £732 a year. Passing over the establishments at Malta, Cape of Good Hope, Gibraltar, and Esquimalt, the chief engineer at Jamaica actually gets £311, against £327 that is received by the engineer in charge at Halifax. Considering the amount of responsibility attaching to such a post as is held by the chief engineer at Hong Kong and Halifax, the *Globe's* correspondent is perfectly correct in considering the inspector of machinery at Garden Island, Sydney, a very lucky man.

The Peace Conference and the Red Cross at Sea.

The Peace Conference has at last achieved its first result. This is the adoption of the ten additional articles to the Geneva Convention, adapting it to naval warfare, drawn up by the Red Cross Sub-Committee. There is no question that the fleets of the various Powers should have a certain number of hospital ships in attendance upon them in time of war.

The present force with which a warship is provided to look after its maimed and wounded is quite insufficient for the number of officers and men who are sure to require attention as the result of a sea fight. Vessels purporting to be hospital ships, visiting the scene of hostilities, must of course have their status clearly defined. It was proposed by the Conference that neutral vessels desirous of rendering aid to the wounded or distressed crews of disabled ships should fly the flag of one of the belligerents. This would mean that certain hospital ships only intended to assist the vessels flying the same flag as themselves, and it is possible that if they interfered, or went to the assistance of disabled or partially disabled vessels before these ships had surrendered, the opposing squadron might resent the interference in a very disagreeable manner. One of the delegates expressed the belief that the Continental Powers would make use of the floating hospitals sent out by "societies of succour recognised by the signatory Governments," whilst this country would depend upon nobody's beneficence, but would equip its own hospital ships. It will be interesting to know the exact details of the ten additional articles to the Geneva Convention which have been agreed to.

Pembroke Dockyard.

The completion of the Royal yacht *Victoria and Albert*, is being proceeded with as rapidly as possible. All her machinery has now been lifted on board, as well as her foremast. The other two masts would also have been put in position if the delivery of some of her rigging had not been delayed. There is not much to be said concerning the armoured cruiser *Drake* which is undergoing construction here, except that as many hands as possible are at work upon her. The new cruiser *Essex*, which is to be laid down here, will resemble the *Drake* in many particulars, especially as regards the protective decks. No. 5 slip, on which the *Essex* will be built, is to be lengthened shorewards. The new sick quarters for Devonport, mentioned in the Navy Estimates, are to have about £2,000 spent upon them this year, although the total cost is to be some £12,000.

From the Lower-Deck to the Quarter-Deck.

The question of the advisability of permitting seamen to rise from the lower-deck to responsible positions on the quarter-deck has been raised by an article in the recent number of the *Saturday Review*, which has special reference to the want of engine-room artificers for the Navy. The writer says that there seems to be some difficulty in securing the services of a sufficient number of skilled artisans for engine-room artificers in the Royal Navy, whilst those who have entered desire an improved position. It appears that no provision exists by which a select few of these men can rise to officers' rank and become engineers. "May not this," he remarks, "deter many from adopting a career which otherwise appeals to them?" It may deter a few, but the writer should have known that the majority of artisans who enter the Navy as engine-room artificers know absolutely nothing about a warship before they make up their minds to enter her Majesty's Navy, and it is only after they have been in the service for a great number of years, and have risen to the top of the ladder in the department in which they are serving, that they have any longing to become engineer-officers. An engine-room artificer, before he enters the Navy, is probably earning his living as an engineer in a big firm on shore, and is affiliated to the Amalgamated Society of Engineers. In this position he has under him a labourer, a man who has not served his time as an apprentice, but yet knows almost as much as the engineer. In a union shop, if this labourer attempted to do the work of a trained engineer, every one of the latter would at once cease work. Thus the engine-room artificer, who wishes to be an officer, is in much the same position towards the commissioned engineer-officer, who has spent years and years studying at Keyham College, as the labourer was to himself before he entered the Navy. He will not permit the labourer to rise to the position of engineer any more than at present engineer-officers would permit artificers to assume commissioned rank. The writer should also bear in mind that almost every engine-room artificer lives on the money he earns at his trade, and that very few naval officers, whether engineer or executive, are able to do this. It is only twelve months since the engine-room artificers obtained warrant rank, and there will be plenty of time to talk of giving them commissioned rank when they have been on trial a little longer. The writer in the *Saturday Review* says that the custom of allowing seamen and artisans to become commissioned officers has been found to work well in the French Navy. Perhaps he will name some instances.

The Naval Manœuvres.

On the 11th of this month, if we have been informed aright, the Naval Manœuvres of this year commence, and the ships of the Channel Fleet and Fleet Reserve are now all busy preparing for sea. It is not as yet known what the scope of operations is likely to be, but it is stated that as many torpedo-boat destroyers as possible are to be put into commission to take part in the operations. If this is so, it would seem to indicate that scouting is to be a principal feature of the manœuvres, and that torpedo-boat destroyers are to be used for this purpose because of the rapidity with which they can approach or retire from a hostile fleet to get and bring back valuable information. As regards the men who are to take part in the mobilisation, it is doubtful if all the ships which are commissioned will have a full crew in spite of Mr. Goschen's optimistic utterances on the subject. As regards mechanics, there is a lamentable deficiency, so that altogether it may be expected that some of the newly commissioned vessels will feel the want of men very badly.

ENGINES OF S.S. "MANCHESTER CORPORATION."

IN our page plate supplement we show a part front and part end view in perspective of the engines which have been built by Messrs. Sir C. Furness, Westgarth & Co., Limited, of Middlesbrough, for the new steel screw cattle and cargo steamer named the *Manchester Corporation*, built by Messrs. Furness, Withy & Co., Limited, at their Middleton shipyard, West Hartlepool, to the order of the Manchester Liners, Limited, of which Sir Christopher Furness is the chairman.

As will be seen from the illustration, the engines are of the inverted triple-expansion type, having cylinders of 28 in., 46 in., and 78 in. diameter respectively, and a stroke of 54 in. operating three cranks. The high-pressure cylinder valve is of the piston type, and the intermediate and low-pressure cylinders have double-ported slide valves. An auxiliary starting valve is fitted to the intermediate cylinder. The low-pressure piston only has a tail rod, and the low-pressure slide valve a balance piston. The connecting rods, which are of best forged scrap iron, are 9 ft. 6 in. long between centres. The valve gear is the ordinary link motion, with a double bar link, all parts are fitted with adjustable brasses, and the rods are supported in adjustable guides.

The reversing gear is of the type having an all-round motion so that it cannot be overrun or damaged, the reversing levers on the weigh shaft being provided with suitable means for notching up each engine separately. A turning engine is fitted on the after end, which gears by a worm into a worm wheel, and is adapted to turn in both directions. The cylinders of the main engines are supported on cast-iron columns, the front having single feet and the back having double feet. The condenser, which is circular, is of cast iron, and is supported on brackets on the back columns. The total cooling surface is over 4,000 square feet, the water circulating twice through the tubes. The ballast pump is arranged to pump through the condenser when desired.

One single-acting air pump is provided, it is placed at the back of the low-pressure engine, and is worked by steel levers operated from the low-pressure piston rod crosshead.

The circulating water is dealt with by one centrifugal pump, having two engines, either of which will drive the pump. This pump is fitted with connections for pumping out the balance tanks overboard without passing through the condenser.

Two single-acting feed pumps are bolted to the air pump hot well, and are worked by the air pump crosshead, so that, if one end of the crosshead should become disabled, the other pump will still be serviceable; and cocks and valve sare fitted so that the pumps can be worked separately and that either pump can be overhauled without stopping the other. In addition to these pumps in the main engines, a pair of Weir's patent direct-acting brass-fitted feed pumps 9 in. diameter and 21 in. stroke are provided.

Two single-acting bilge pumps are also fitted on the hot well and are worked and arranged in a similar manner to the feed pumps.

The crank-shaft is of good forged iron and is built up in three interchangeable elements. The angle of the cranks to one another is equal, the high-pressure crank leading. The diameter of the shaft is 16 in. and that of the crank 16 in. also, with a length of 17 in. The propeller shaft in 17 in. diameter and is covered with brass casing, an indiarubber ring being provided between the propeller and the end of the brass liner to prevent corrosion. The tunnel shafting is of iron 14½ in. diameter, increased to 14¾ at the bearings.

The thrust-block has horseshoe collars lined with white metal, and the thrust-shaft collars run in an oil bath.

The propeller is of cast iron and has four detachable blades.

The boilers are three in number and are single-ended, they have a mean diameter of 14 ft. 9 in. and are 12 ft. long over the tube plates. The tubes

THE NEW
PUBLIC LIB

are wrought iron lap-welded, and 2½ in. diameter and 8 w g thick. The water space between the tubes is 1¼ in., and the length of the tubes between the tube plates is 8 ft. 3 in. The boilers have each three furnaces 3 ft. 10 in. in diameter, of the suspension type, and are arranged with 5 in. water spaces between. They are designed for a working pressure of 190 per square inch.

Howden's system of forced draught is fitted to the boilers, the draught being produced by one double inlet fan 84 in. diameter driven direct by two engines 7 in. diameter. The funnel is 9 ft. diameter, and is taken up about 80 ft. above the fire bars.

The I.H.P., for which the engines have been designed is 3,000 at 70 revolutions per minute.

ELECTRICAL NOTES.

(From our own Correspondent.)

Marconi's system of wireless telegraphy was under test again, and a record result was obtained. The distance which the waves were sent was in this last case 28 miles, and no difficulty was experienced in the reception of the messages. M. Marconi is on his way to the United States to superintend the fixing up of the apparatus for his system to be in use in the international yacht race. One set of apparatus will be on board the *Columbia*, and the other on shore. The records of the race will thus be chronicled as in the regatta at Dublin.

Cantilever Electric Crane.—Three cranes are under construction for the William Cramp & Sons' Ship and Engine Building Co., Philadelphia, and one of them has just been put in operation. It is driven by a single electric motor of about 150 H.P., of the Elwell Parker type, and built at their works, Cleveland. The crane is mounted on a steel trestle, which runs alongside the ship under construction. The travel of the crane along this trestle is 725 ft., and the underside of the cantilever is 92 ft. from the ground. Its lifting capacity is 15 tons at 60 ft. out on either arm, and five tons at 95 ft. The total length of the cantilever arms in all is 202 ft. The gauge of the track along which the crane runs is 20 ft., and the crane has a speed up and down the trestle of from 500 to 700 ft. per minute against the wind. It hoists its maximum load 125 ft. per minute, or five tons 350 ft. per minute, or 1,000 pounds 700 ft. per minute, and the trolley can travel along the cantilevers at 800 ft. to 1,000 ft. per minute. It covers two battleships. At present there is on its right side a 13,000-ton battleship for the Russian Government, and on the left is the keel of the new battleship *Maine*.

Electrical Ventilating Fan.—The Sturtevant Co., New York, are putting much care into the construction and improvement of electrical fans. The wheel consists of eight blades secured to a hub, and held in their relative positions by a hoop at the periphery. The temperature rise of the motor after 10 hours' run is 27 to 30 degrees Fahr., against 60 degrees to 80 degrees frequently met with in practice. The design of the motor has been made to fulfil the following conditions: (1) The production of a magnetic field of the greatest possible quantity in proportion to the rated horse-power. (2) The excitation of this field with the least possible consumption of energy. (3) Suitable material for poles to eliminate eddy currents, and heat less therein. (4) Pole pieces of such design as to prevent distortion of magnetic field by armature flux, and the consequent low reduction of the self-induction of the armature coils. (5) Arrangement of magnetic circuit so that the leakage is small. (6) An armature in which the core and resistance losses are reduced to a minimum. In a 1-2 Kilowatt 500-volt motor, an efficiency of 30 per cent. was obtained when running 1,300 revolutions per minute, and a load of 175 per cent. can be carried with no sparking at the brushes. They are built of the two-pole type from ¼ to 3 H.P., and multipolar from 3 to 20 H.P. The fans are from 18 in. to 120 in. diameter.

Maxim Direct-Coupled Generator Set.—There is a very excellent and compact set consisting of a Lundell generator driven by a Forbes-Maxim type engine. It is rated at eight kilowatts when running at a speed of 500 revolutions per minute. It is fitted in the steam yacht *Postmaster General*, which is doing duty in New York Harbour. It is capable of developing 10·8 kilowatts, and did so in trial sufficient to supply 216 lamps. The total weight is 1,050 lbs., or about 100 lbs. per kilowatt output. The space required for the installation is 27 in. wide by 6 ft. 2 in. long, the height being 38 in. The armature is series-wound, and a single field coil is used, which magnetises all the different field poles to the same degree by intensity.

The Nernst Electric Lamp.—The new thing in electric lamps is this one which has been brought under public notice in England by Mr. Swinhorne. Refractory oxides are worked up into little rods, and these are rendered incandescent by sending a current through them. The rods are united in two platinum wires, by means of paste made of refractory oxides, and these rods, although good insulators when cold, become conductors when heated. Resistance falls with increase of temperature, and increase of light rises with increase of current. This tendency is corrected by a series resistance of fine wire amounting from 10 to 12 per cent. of the whole resistance of the lamp The necessary electric energy is 1·5 watts per candle for large lamps and 1·6 for small ones. It is evident that, like the oil engine, a starter is required, since the rods are insulators when cold. These rods have therefore to be heated with a lamp or match to begin with, or they may be heated with a heating resistance placed near the rods. A 16 c.p. incandescent lamp requires about 60 watts per hour; the Nernst lamp requires about $16 \times 1·5 = 24$ watts. It requires also less watts per hour than an equivalent arc light.

Electric Pumps for Canals.—In dry seasons the supply to the high-level reaches of the Bourgogne Canal are deficient, and electrical pumping plants have been provided at the different locks to raise water from the low to the high levels during these seasons. There is a waterfall near the canal and this has been utilised to transmit power to the pumps. The system is three-phase current at 2,000 volts. Centrifugal pumps driven by motors on the same axles are used to raise the water. The pumping of the water costs one-tenth what it would cost to provide extra water in the main reservoirs.

Candle power for candle power the arc light is run at much less expenditure of electrical energy than the incandescent light, and as a substitute for the expensive incandescent lamp **Messrs. Johnston & Phillips** introduced the midget arc lamp, which used a very small current indeed. We do not know how far this small arc lamp has been successful, but they now make a speciality of a lamp which they call the "Well," of a very efficient kind. This lamp is made both for alternating and continuous current, and for any potential. It has one advantage which will appeal to most, namely, its extremely low price, £5, for single lamps, and it is reliable. To obtain the soft diffused light special globes are used, and the light given is about 2,000 candles per 500 watts. The life of the carbons is almost as long as that of the filament of an incandescent lamp. Lamps which are in parallel, and series using four amperes, have a carbon life of 220 hours, and they thus burn about twenty times as long as the ordinary type lamp. The maximum rays from the lamp come out at about 25 degrees downwards, measured from the horizontal, and there is thus a distribution of light at long ranges, whilst the light beneath the lamp is quite abundant. Practically the only moving part is the armature, which is held in suspension whilst the lamp is burning. The cost of burning is said to be very low, and works out at one-eighth of a penny per 500 candle-power, which is eight times better than that claimed for the cost of incandescent gas lighting. There are some 17,000 of these lamps in use.

The Broadheath Works of the Linotype Co., near Manchester, have followed in the wake of Messrs. J. & G. Weir Cathcart, and are remodelling their shops with electric motors. The machine tools are run from shafting driven by motors of 5 or 10 H.P. Tests have been made with the separate shafts and motors. One a 2¼ in. shaft, 93 ft. in length, in ten bearings, required ·42 H.P. at 200 revolutions per minute, or ·042 H.P. per bearing, and a similar shaft required ·052 per bearing. The power of the shops is 75 kilowatts, and the efficiency of the generating plant 80 per cent., the running cost is ·94d. per B.T.U. Both lighting and power are supplied from the same generating plant.

NAVAL ENGINEER APPOINTMENTS.

The following appointments have been made at the Admiralty from May 25th to June 24th, 1899:—

Barr, E., engineer to the *Duke of Wellington*, for the *Canopus*, to date May 27th.

Bishop, T. H. B., engineer to the *Pembroke*, for the *Dasher*, undated.

Bryan, R., engineer to the *Vivid*, for the *Ocean*, to date May 30th.

Coad, H. J., engineer, to be chief engineer in her Majesty's fleet.

Coopper, H., engineer to the *Duke of Wellington*, for the *Chamois*, to date June 7th.

Cottam, F. W., staff engineer to the *Pembroke*, for the *Astræa*, to date June 5th, and for recommissioning, to date June 15th.

Dart, F. H., chief engineer, has been advanced to the rank of staff engineer in her Majesty's fleet.

Green, R. W., chief engineer, has been advanced to the rank of staff engineer in her Majesty's fleet.

Griffin, D., fleet engineer to the *Pembroke*, for the *Immortalité*, undated.

Hart, A., chief engineer to the *Pembroke*, for the *Vindictive*, to date June 5th.

Huddy, J. B., engineer to the *Vivid* (supernumerary), to date June 12th.

Irish, H. W., engineer to the *Victory*, for the *Lightning*, to date June 9th.

Johnson, C. H. (probationary), assistant engineer to the *Repulse*, to date June 12th.

Kempt, A. C., assistant engineer to the *Renown*, to date May 27th.

Kirwin, J. J., assistant engineer to the *Vivid* (supernumerary), to date July 1st.

Larg, A. D., assistant engineer to the *Renown*, to date June 12th.

Lawrance, W. W., engineer, has been promoted to the rank of chief engineer in her Majesty's fleet.

Lawton, W. R., engineer to the *Duke of Wellington*, for the *Ranger*, to date June 9th.

Lumsden, W. G. G. P. (probationary), assistant engineer to the *Edgar*, lent, undated.

Martell, P. D., engineer to the *Victory*, for the *Fawn*, to date June 7th.

Meadus, H. H., staff engineer, has been advanced to the rank of fleet engineer in her Majesty's fleet.

Moore, C. A., chief engineer, has been advanced to the rank of staff engineer in her Majesty's fleet.

Owen, R., engineer, to be senior engineer R.N.R.

Page, F. J., engineer to the *Vivid* for the *Fervent*, to date June 22nd.

Parnall, W. R., assistant engineer to the *Vivid* (supernumerary), to date July 1st.

Pearce, W. W., engineer to the *Vivid*, for the *Lynx*, to date June 13th.

Pethick, E. E., assistant engineer to the *Nile*, to date May 27th.

Reynolds, J. A., engineer to the *Pembroke*, for the *Basilisk*, undated.

Shattock, T., engineer to the *Edgar*, lent, undated.

Sillince, W. P., assistant engineer to the *Duke of Wellington* (supernumerary), to date July 1st.

Thompson, G. F., engineer to the *Duke of Wellington*, for the *Conflict*, to date May 27th.

Toop, W., engineer to the *Vivid*, for the *Lynx*, undated.

Toop, W., engineer to the *Vivid*, for the *Opossum*, undated.

Turner, W. F., chief engineer, has been advanced to the rank of staff engineer in her Majesty's fleet.

Webster, G. P., engineer to the *Vivid*, for the *Zephyr*, to date June 22nd.

At a recent meeting of the Clyde Steam Ship Owners' Association, the committee elected Mr. Hugh Gibb (of Messrs. Cayzer, Irvine & Co,) and Mr. George Sloan (of Messrs. Wm. Sloan & Co.) to represent the Association upon the Board of *the British Corporation for* the Survey and Registry of *Shipping*.

INDUSTRIAL AND TRADE NOTES.

THE CLYDE AND SCOTLAND.

(From our own Correspondent.)

WHILST great briskness continues to characterise operations in the shipyards and engine shops of the Clyde, as evidenced by the large number of launches and trial trips, the past month has seen no improvement, but a much more accentuated cessation, in the placing of new orders. Not one of any importance has been recorded up to the date of writing—24th ult.—and if any have been booked the builders have kept their own counsel remarkably well. Enquiries are not unknown, but these are more in the nature of "feelers," and owners who contemplate adding to their fleets prefer to wait uncommitted—although good delivery is not now so impossible a matter—until the prices of materials are somewhat less than they are.

One of the trade sensations of the month has been the failure of Messrs. Neilson Brothers, the well-known iron and steel merchants, of Glasgow. A statement of affairs was submitted at a meeting of the principal creditors, held on the 6th ult., and this showed liabilities amounting to £150,791, and assets amounting to £22,713, which leaves a deficiency of £128,078. The principal creditors and the amount of their claims are as follow:—The Dowlais Iron & Steel Co., South Wales, £21,754; Messrs. Harland & Wolff, Belfast, £21,713; Vickers, Sons, & Maxim, Barrow, £15,589; Clydebank Engineering & Shipbuilding Co., £9,926; Fairfield Shipbuilding & Engineering Co., £6,318; W. Beardmore & Co., Parkhead, £6,195; Glasgow Iron & Steel Co., £5,764; Arroll Brothers, Glasgow, £4,491; Workman & Clark, Belfast, £4,896; Charles Connell & Co., Glasgow, £4,716. Amongst the secured creditors are the Royal Bank of Scotland for £24,237; Mr. Robert Mackill, shipowner, Glasgow, for £16,293; and Messrs. Holms-Kerr & Hedderwick, accountants, for £14,839. The trade accounts amount to £53,335; claims for unfulfilled contracts, £86,710; and the balance is made up of small accounts. A committee, representing the principal shareholders, have investigated and reported on the state of affairs submitted, and recommended the acceptance of 2s. in the pound.

With the beginning of the month rumours and statements, claiming more or less to be well authenticated, began to be circulated as to an amalgamation between an important Clyde shipbuilding firm and one of the great Sheffield steel-working and armour plate-making concerns. After corrections as to these rumours and statements being "premature and unauthorised," subsequent events soon proved that, whilst perhaps unauthorised, the statements had solid fact behind them, and that the great concerns to be combined were those of the Clydebank Shipbuilding & Engineering Co., Limited, and Messrs. John Brown & Co., Limited, Sheffield.

The first explicit and official announcement made with regard to the matter—which, as can well be understood, excited from the first very great interest throughout Clydeside engineering and commercial circles—was contained in the annual report of Messrs. John Brown & Co., published on the 13th ult., in the course of which it was stated that "a favourable opportunity has arisen for strengthening the business of the company by the acquisition of one of the best equipped and most successful shipyards and engineering works in the United Kingdom. A provisional contract has been made with the Clydebank Engineering & Shipbuilding Co., Limited, for the purchase of their property and business as a going concern on terms which the directors consider to be favourable to the shareholders."

The necessary resolutions for carrying out the above arrangements were proposed and carried at the general meeting of the Sheffield company held on the 22nd ult. From these it transpires that the arrangement involves:—The purchase of the whole of the property, business, and goodwill of the Clydebank company, and the undertaking, carrying out, and fulfilment of that company's liabilities, contracts, and engagements; the carrying on of the business of shipbuilders and shipowners, dock and wharf owners, and dealers in all materials and things required or usable in the building, fitting, armament, equipment, and repair of vessels of every kind, whether vessels of war or for merchant service; the carrying on of the business of mechanical engineers, including the manufacture of, and dealing in, marine or other engines, stationary or locomotive boilers, ordnance, guns, and other weapons, arms of all kinds, armour plates, shells, shots, projectiles, ammunition and targets, and all accessories thereto respectively; the increase of the nominal capital of the company to £2,500,000, by the issue of 48,000 preference shares of £10 each, to rank *pari passu* with the existing preference shares, and 500,000 ordinary shares of £1 each; the subdivision of the original capital of the company of each ordinary share of £20 upon which £15 has been paid into 20 shares of £1 each, upon which 15s. shall be credited as paid up.

The firm of Messrs. John Brown & Co., Limited, was established in 1864, and the capital consists of £1,250,000 in ordinary shares of £20; £270,000 in 5 per cent. preference shares of £10, and loans at 3 to 4½ per cent. to the amount of £263,045. The concern for the last 15 years at least has paid dividends ranging from 5 to 7½ per cent., the dividend for the last financial year having been 10 per cent. on the ordinary shares of the company. The Clydebank Engineering and Shipbuilding Co., Limited, was registered in 1890 to take over the business of the firm of James & George Thomson. The authorised share capital was £250,000 in shares of £10, all of which was issued to the vendors as fully paid. Mr. W. A. Donaldson, of Cochno, is chairman, and the other directors are:—Messrs. J. R. Thomson, J. G. Dunlop, A. S. McClelland, J. P. Smith, and G. P. Thomson. Not counting the vessels launched this year, the number of vessels of all kinds built at Clydebank has been 165, of which 116 were merchant vessels, and 49 vessels of war, 28 of the latter being for the British Government. The largest merchant vessels produced were the *Paris* and *New York*, each of 10,700 tons, and the largest warship the *Jupiter*, of 14,900 tons displacement.

Scott's Shipbuilding and Engineering Co., Limited, which, as recorded in last month's Notes, is the new joint-stock title of the firm formerly, and for a very long period, known as Messrs Scott & Co., Greenock, have recently built handsome new offices, and an extensive block of shops, including those for joiners and carpenters and for mould loft purposes, and in other ways are equipping themselves for undertaking a larger amount of work than ever. In view of the changed title, it is of interest to place on record that Messrs. Scott & Co. claim to be the oldest shipbuilding concern in the United Kingdom. Some years ago, in writing to a shipping journal correcting some misstatement as to the age of the firm, Messrs. Scott & Co., said:—"The great-great-grandfather of the present partners of our firm commenced the business of shipbuilding at Greenock in the early years of last century. This business has been carried on here from father to son for five generations without intermission. During the period of nearly 200 years every partner of the firm has been of the name of Scott, and a lineal descendant of the founder. We may add that the marine engineering business established in 1824 by their grandfather, in connection with his shipbuilding firm, under the style of Scott, Sinclair & Co., is still carried on by our present partners at the Greenock foundry." It is about 50 years ago that this business was placed under the same control as the shipbuilding concern.

About 10 years ago the firm, to meet the demands of increasing business, purchased the iron shipbuilding yard, wood-yard, and graving dock in Greenock so long occupied by the firm of Steele & Co.; and, as showing the amount of work turned out by the Messrs. Scott, it may be stated that, from the taking of the extensive premises mentioned, the total output of steam and sailing vessels has been 170,000 tons. Among the numerous important orders the firm have at present on hand are several large cargo steamers for the Ocean Steamship Co. of Liverpool, for whom they have all along built extensively, and a large palatial steam yacht of 1,800 tons for Mr. A. J. Drexel, of Philadelphia, from the designs and specifications of Messrs. G. L. Watson & Co., Glasgow. This magnificent private steam yacht is 272 ft. long and 36 ft. 6 in. beam, and will cost, it is believed, £100,000. She will be the first yacht to be owned by an American under the recently adopted law, which requires him to pay entrance and clearance fees at every port in the United States which his yacht visits, the same as any other foreign merchant vessel owner.

Messrs. Chambers Brothers, launch builders, Greenock, have received another order from Messrs. Harland & Wolff, Belfast, for six of their patent collapsible lifeboats, which makes 18 for this firm alone. Messrs. Caird & Co., Greenock, have given an order for ten of the boats from Messrs. Chambers, who have 50 on hand at present.

At the Dalzell Steel and Iron Works, Motherwell, a record output in steel smelting has been attained of late with the three large 50-ton furnaces, which were started last year in No. 3 smelting shop. The record output for the last six weeks has averaged somewhat over 1,500 tons per week, and during the past eight months or so 500 tons of ingots per week have frequently been turned out per furnace. The production of the Dalzell Steel and Iron Works now runs to more than seventeen times the output of the original works in the seventies, this representing over 17,000 tons of finished steel and iron per month.

The management of the Steel Company of Scotland has recently undergone a change. Mr. A. McLellan, who has filled the post since the retirement of Mr. James Riley seven or eight years ago, having accepted the position of manager of the Carron Iron Co., Mr. W. Clark, who has occupied the position of secretary to the Steel Co. for a considerable number of years, has been appointed manager in his place.

In the early part of the month just closed the Dutch steam tug *Svaartee* arrived in the Clyde and took in charge, for towing to Rotterdam, the Anchor liner *Devonia*, and some days thereafter a similar tug, the *Ocean*, arrived for the *Circassia*, a sister ship, both having been sold to Dutch owners. The *Ocean*, in entering the Gareloch, where the Anchor liners have been laid up for some time, got aground on Row Spit, but got off safely, and in due time departed again with her charge. The tugs themselves attracted some attention, being powerful-looking and well-equipped deep-sea towing vessels, 160 ft. in length, 30 ft. beam, and with bunker capacity of 600 tons. They were fitted with a large drum, controlled by a separate engine, which hauls in and pays out the towing hawser.

With the departure of the *Devonia* and *Circassia* from the Gareloch there will only be three vessels left in this well known haven for old or uncommissioned ships, these being the old Anchor liner *Utopia* (which, as will be remembered, was raised after being sunk a good few years ago), the *Waldensian*, and the *Alaska*, formerly of the Guion fleet. The last-named, however, will also soon be taking her departure, having recently been bought—it is believed for breaking-up purposes—by Mr. Thomas W. Ward, of Sheffield, the price paid being £17,500. The *Alaska* was the first vessel to which the term "Atlantic greyhound" was applied. Having a tonnage of 7,000 and proportionate power, and turned out from Fairfield in 1881, she created a record, and disputed for a time the premiership of the Atlantic with the Cunard and Inman liners. As such vessels go, however, she is now an "old stager." Her last service was the carrying home to Spain of some thousands of soldiers on the conclusion of the war with America.

The Clan Line Steamship Co., Glasgow, are gradually transforming their fleet from vessels of the ordinary type to those of the turret-deck type, and already of the 50 vessels, built and building, which comprise the fleet, as many as 16 are of the turret class. Messrs. W. Doxford & Sons, Sunderland, the holders of the patent, have built or are building all these vessels with the exception of two which were built at Barrow under an arrangement with the patentees. Messrs. Doxford have at present three turret-deckers on hand for the Clan Line, and five others will follow as speedily as possible. These range in length from 380 ft. to 450 ft. The Clan Co., however, have not altogether forsaken the ordinary type of steamer, for they have at present two building in Clyde yards—one at Messrs. A. Stephens & Sons', Linthouse, and the other at the yard of Messrs. Blackwood & Gordon, Port-Glasgow.

Messrs. Menzies & Co., engineers, shipbuilders, and ship-repairers, Leith—one of the oldest shipbuilding firms in the kingdom, and notable as having built, in 1837, the *Sirius*, which with the *Great Western*, was the first steamer to cross the Atlantic—have acquired the shipyard at Inverkeithing, on the Fifeshire side of the Firth of Forth, occupied until recently by Messrs. Cumming & Ellis. They purpose carrying on the work there of ship construction and repair as an adjunct and complement to the engineering part of the business at Leith. The demand at that port, in the matter of engine and boiler work, has been such as lately to cause the firm to double their shops and lay down a variety of the most efficient modern tools. This enterprising firm have bought the plant, machinery, and stock-in-hand at the Inverkeithing yard, and two trawlers in course of construction as well. They intend making a speciality of the building of trawlers and small cargo boats on their newly acquired premises. We understand that, in conjunction with their well equipped engine shops at Leith, the firm are now in a position to contract for the complete building of hulls and machinery, and have just received an order for two trawlers 120 ft. long, to be fitted with triple-expansion engines. The firm have two dry docks in which they conduct their ship-repairing work at Leith, and in addition there is a patent hauling-up slipway at Inverkeithing yard, suitable for the repair of smaller vessels.

The death took place at Helensburgh, on the Clyde, on the 31st May, of Mr. Robert Darling, manager, and to a large extent creator, of the fine fleet of passenger paddle-steamers owned by the North British Railway Co. plying on the Clyde. Previous to taking up duty in the Clyde district, Mr. Darling was secretary of the North British Packet Co. at Burntisland, on the Firth of Forth. On the company starting a steamboat service on the Clyde in connection with the railway service, Mr. Darling was given charge of the Clyde steamers. At that period the company only owned two vessels, but 16 years ago, when the fine railway terminus of Craigendoran was opened, the fleet was greatly added to. Under the fostering care and excellent management of the deceased the service grew in importance, and the fleet of steamers increased in numbers. Within the past two or three years the fleet has been augmented by the paddle-steamers *Talisman* and *Red Gauntlet*, which are among the fastest of their size on the Clyde, and it is a melancholy coincidence that in the same week which saw the demise of Mr. Darling there was launched from the yard of Messrs. A. & J. Inglis, Pointhouse, the paddle-steamer *Waverley*, the latest and largest, and intended to be the swiftest, of the North British fleet.

The *Waverley* is the only addition to the list of Clyde summer boats this season, and, if rumour may be believed, the other railway companies will require to build again if they are to keep ahead. The number of pleasure steamers on the Firth of Clyde is now very large, and a few figures may be of interest. There are 38 steamers in all, aggregating 12,911 tons gross. The Glasgow and South-Western Railway Co. own ten, of 3,677 tons; the North British Railway Co. nine, of 2,632 tons; the Caledonian Railway Co. ten, of 3,081 tons; Mr. David McBrayne two, of 958 tons; Captain John Williamson three, of 749 tons; Captain Buchanan two, of 566 tons; the Loch Goil and Loch Long Steamboat Co. two, of 494 tons; the Glasgow and Inverary Steamboat Co. one, of 466 tons; and the Glasgow Steamers, Limited, one, of 268 tons. The Glasgow and South-Western own the two biggest boats—the *Glen Sannox*, of 610 tons, and the *Juno*, of 600 tons—and they have also the highest aggregate tonnage. There are, of course, a large number of coasting screw-steamers, which sail from Glasgow, touching at the coast ports, but these cannot, properly speaking, be included in the Clyde summer passenger fleet.

The engineering section of the Glasgow International Exhibition, 1901, already promises to be well worthy of the Clyde as the head centre of marine engineering and shipbuilding. At their last meeting the Marine Engineering and Shipbuilding Committee had under consideration the arrangements connected with their department. These included a very large number of offers for appliances which will be required. Messrs. Penman & Co., Glasgow, offer to supply Lancashire boilers and water-tube boilers, and the latter class of boilers are also offered by Messrs. Babcock & Wilcox, Renfrew; Humphrey & Tennant, London; Stirling & Co., Edinburgh; Weir's, Limited, Cathcart Berry, Manchester, and other firms. It is estimated that the total steaming power required for the purposes of the exhibition will be about 5,000 H.P., and the committee have already received offers to supply more than that power These offers are really of exhibits on loan. It was resolved to have, if possible, separate iron chimneys for each maker's exhibit in order that the working of each exhibit may be shown separately. The committee have also received offers for motors, electric lighting plant, lamps, and indeed for all other appliances connected with the illumination of the building and grounds of the exhibition. They have received offers from a number of well-known firms for the supply of engines and dynamos, some of which will develop as much as 1,200 H.P. All these points were considered at the meeting, and they were postponed for further consideration, when fuller information will be laid before the committee.

In connection with this section it may be mentioned that the Institution of Engineers and Shipbuilders in Scotland are organising an International Congress, to be held in Glasgow in 1901, which will be conducted on similar lines to that which was held in Chicago during the World's Fair.

Very special efforts are being made by the committee to render marine engineering and shipbuilding a leading feature of the exhibition. Their intention is to have exhibits of models of ships, which will at a glance enable the visitor to grasp the many epochs of progress that have been made in the construction and working of vessels during the century. The models will be subclassed into passenger ships, cargo ships, men-of-war, yachts, &c. They will show the transition stages of conversion: from wood to iron and steel, from sail to steam, from paddle to screw, from single to compound engines, from compound to triple-expansion engines, and other interesting directions in which development has progressed. So far, the committee are confident of making this section an unspeaking history of the advances in every department. From the year 1860 that will be no trouble; but, to ensure completeness with respect to the period preceding, they have issued a circular to shipbuilders and shipping companies asking for information as to models that might be at their disposal. The committee are also arranging with the Clyde Trustees for that body to show clearly the results of their work on the Clyde by means of models of the river, representing it as it existed in the year 1800 and as it will be in 1900. These will be made to show also the increase in the area occupied by shipyards and engine works and in the growth of docks, wharfage, &c. The engineer and electrician for the exhibition is Mr. Thomas Young, C.E., Glasgow, who held the same important post during the exhibition of 1888, as well as at other international exhibitions in Edinburgh and Newcastle.

THE TYNE.

(From our own Correspondent.)

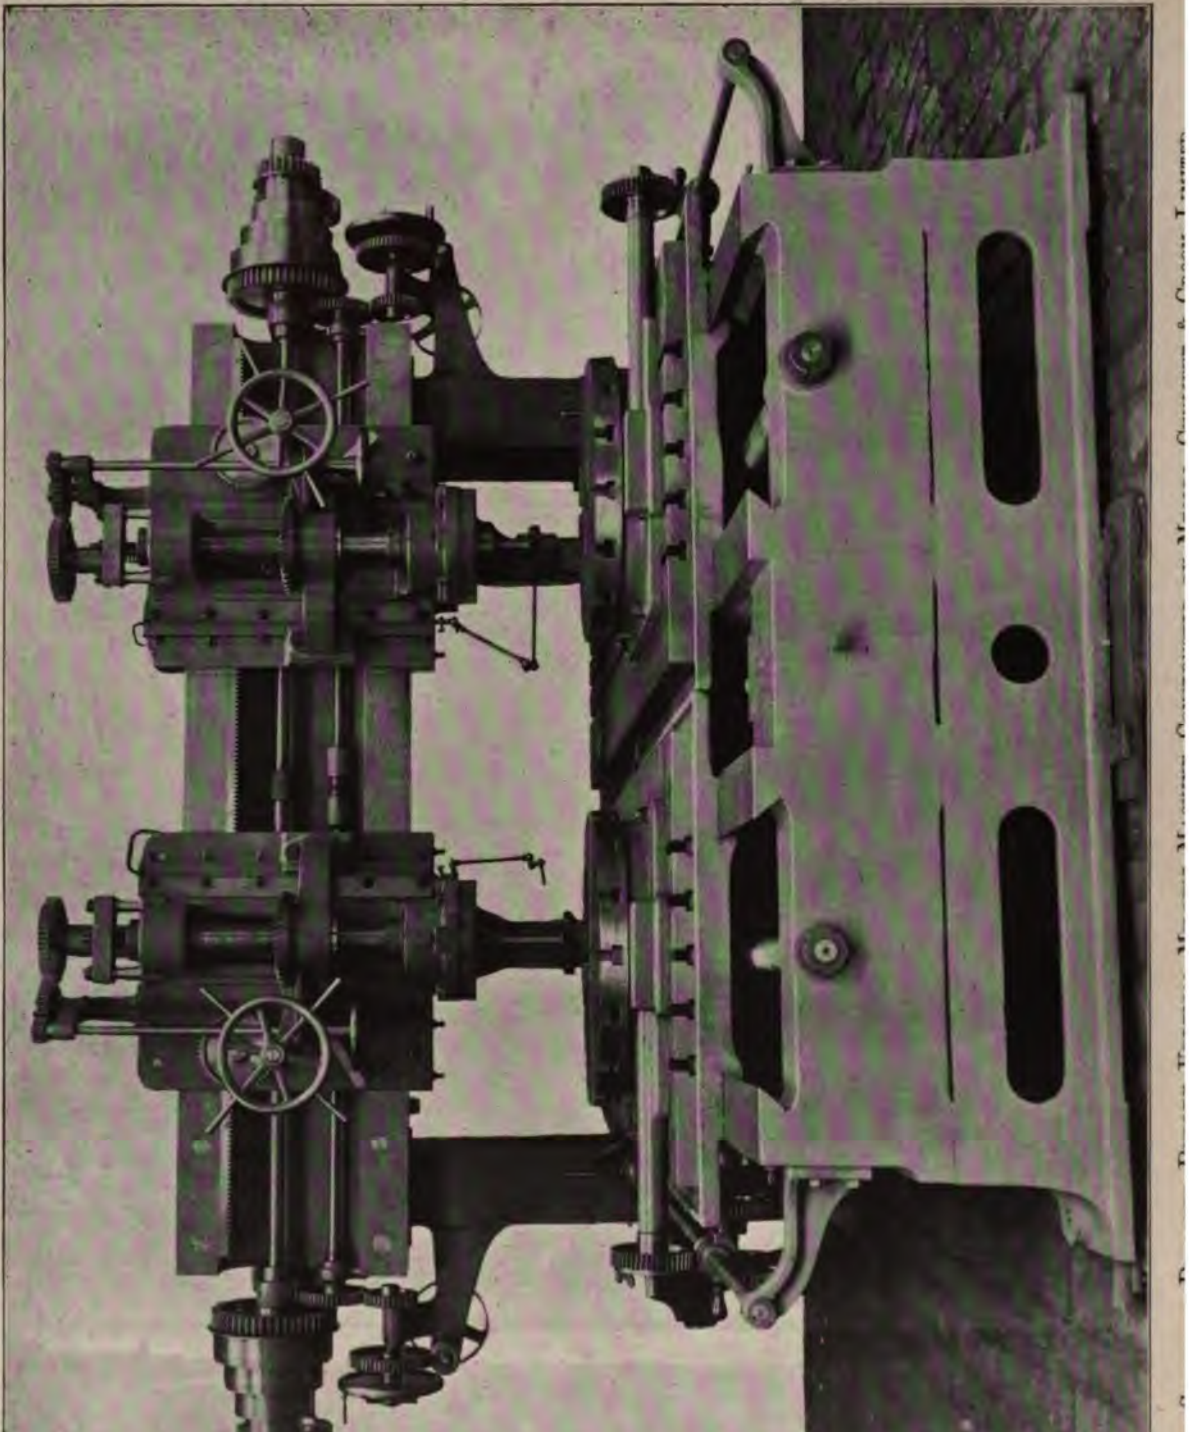
Shipbuilding.—During the month, a fair amount of tonnage has been launched on the Tyne, and the weather having been favourable for outdoor work, contracts at all the yards have been well advanced. The reconstructed s.s. *Milwaukee* has been successfully floated, and will shortly be ready to proceed to sea again, and it is to be hoped she will be more fortunate on her second maiden voyage than on her first. It is needless to repeat the history of this vessel, which has been amply dealt with in previous numbers; but at this juncture it will not be out of place to say that the salvage and reconstruction of the vessel constitute two of the most remarkable achievements that have ever been recorded in connection with the industry of shipbuilding.

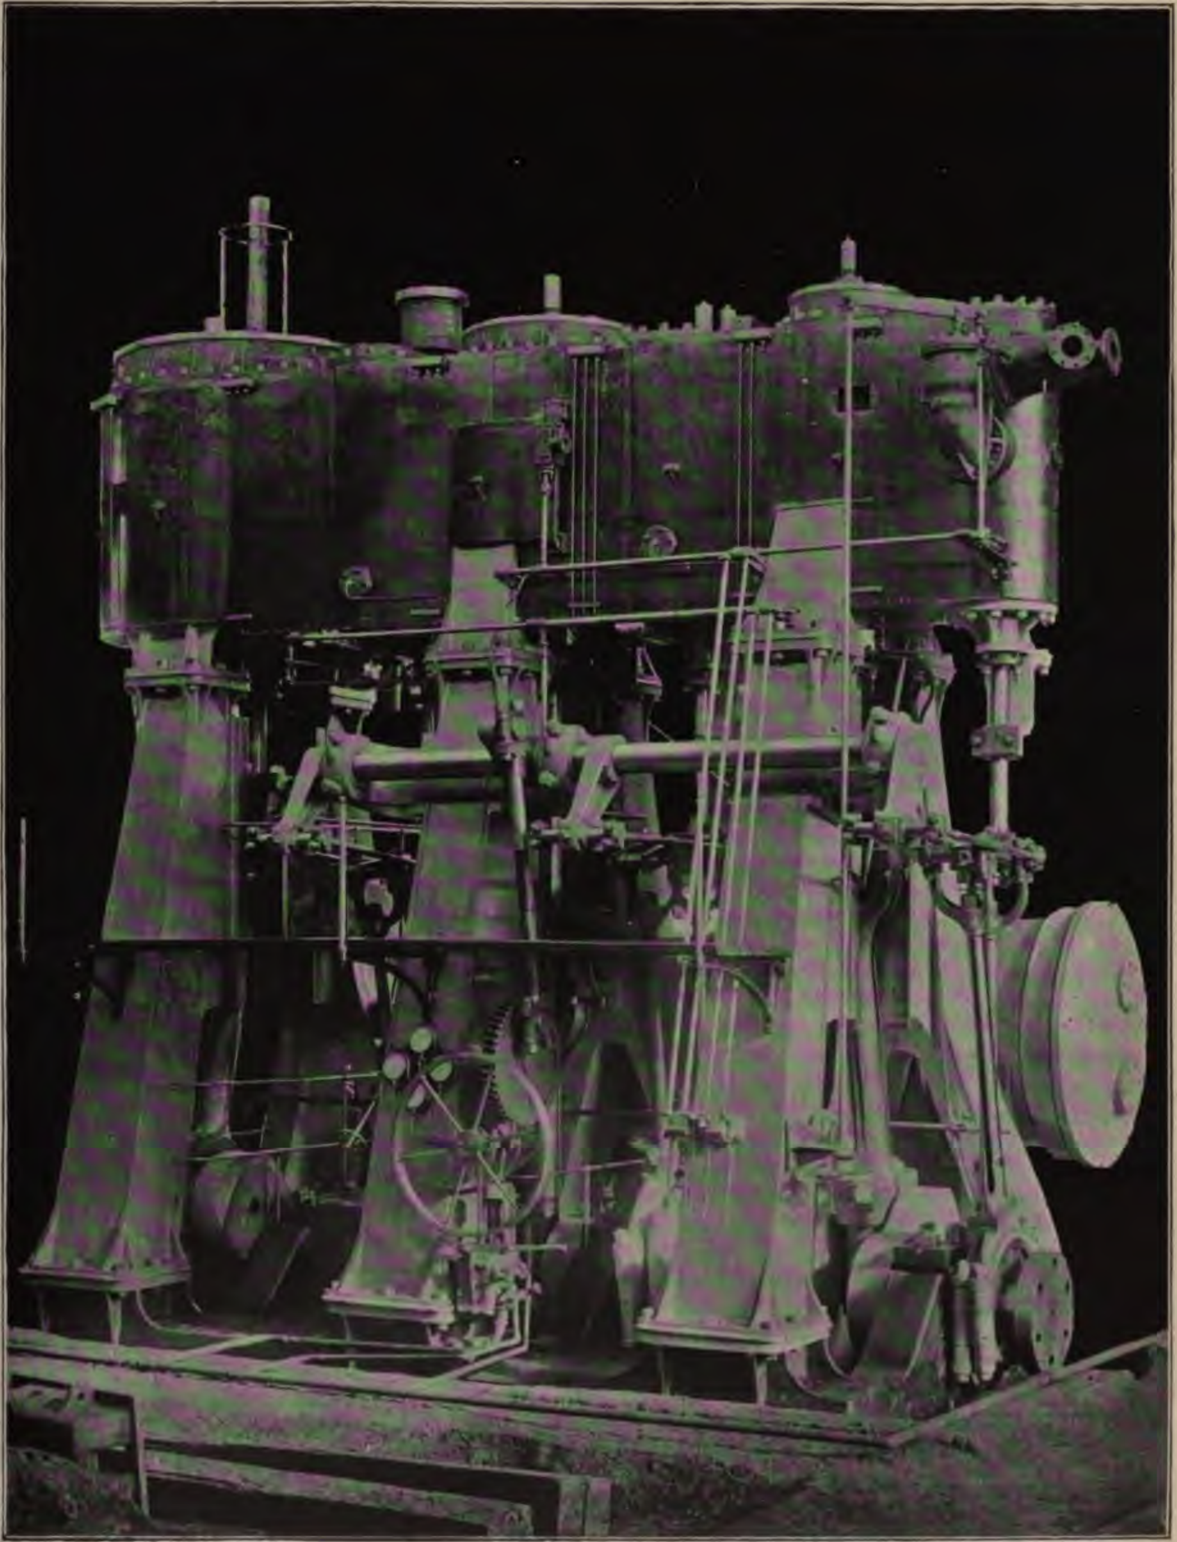
Only one order of importance has been heard of as having been booked lately, and that is a vessel of the very largest dimensions, placed with Messrs. C. S. Swan & Hunter by Messrs. Elder, Dempster & Co. This vessel is to have six large boilers, which, with the machinery, are to be constructed on the Tyne. It is understood to be a high-class cargo boat; but there will probably be accommodation provided for a limited number of passengers, and the vessel will be fitted with every modern appliance calculated to promote comfort and efficiency. The pontoon yard belonging to this enterprising Wallsend firm is still unoccupied; but rumours are afloat respecting negotiations for an exceptionally important contract, and it is confidently expected that long before the advent of winter the yard will be in full swing again.

Messrs. Armstrong, Whitworth & Co. have, as we anticipated, obtained from the Tyne Commissioners the permission asked for to strengthen by pile-driving the foundation of the river foreshore adjoining their Low Walker yard, with a view to the lengthening of their building berths. The steadily growing tendency to increase the size of vessels, which is everywhere noticeable among shipping people, has made a lengthening of the berths imperative in this, as well as in other cases, and as the company had already gone as far as was possible with their extensions in the opposite direction, all that remained for them was to complete the work by reclaiming a portion of the foreshore. The company have at present a large amount of mercantile work in hand, in addition to the warships—among the former class of contracts being a large vessel for the West India and Pacific Steam Navigation Co., and several large boats of Swan's patented design for the carrying of petroleum in bulk.

Messrs. Wigham, Richardson & Co.'s yard continues very active, and at Messrs. Hawthorn, Leslie & Co.'s yard, at the other side of the river, the berths are fully occupied with torpedo-destroyers, cattle ships, &c.; whilst in the graving dock, and in the river beside the yard, vessels are being fitted out or repaired.

The Palmer Co., having at the end of April launched the fine vessel *Manchester Port*, lost no time in placing another keel in the vacated berth, and the framing work of the vessel is now well advanced. The quite natural disappointment which was felt throughout the locality in reference to the





Triple-Expansion Engines of s.s. "Manchester Corporation," Built by Messrs. Sir Christopher Furness, Westgarth & Co., Limited, Middlesbrough.

failure of the company to secure a larger portion of Government work than recently fell to their share has by this time given place to a feeling of thankfulness that there is an abundance of mercantile work in hand, and that full activity is assured in the yard for at least another seven or eight months. The Howdon yard belonging to the company is still, unfortunately, idle, and there seems to be no likelihood of the machinery being set going this year.

The Tyne Shipbuilding Co. have as much work in hand as they can conveniently deal with, and at the Northumberland yard there are four vessels on the stocks, and other orders to follow. The proprietors have launched their second vessel (which is now about ready for sea), and one of those on the stocks is well advanced towards completion.

The launching of two vessels in a year is not a very remarkable result, but it must be recollected that some time was occupied with preliminary work before the actual work of production got properly under way, and the inadequacy of the labour supply, especially in the plating and riveting departments, was felt from the first. In this, the second year of the company's existence, no doubt a different state of things will be witnessed; and, as the yard is both well equipped and well managed, it is reasonable to expect that the successes of the future will be sufficient to repay everyone connected with the forming of the company and the opening of the yard, for their labour and enterprise.

It is reported that Messrs. Readhead have recently added to their prospective work engagements an order for two steamers of a large and superior class. The information is, however, not authentic, and we can only give the statement for what it is worth. As Messrs. Readhead have never been known to be short of work during the past half score of years; and, as they launch a vessel almost every month, it seems clear that no very long interval can elapse without new orders being booked by them, and there is consequently some reason to suppose that the rumour referred to is correct. At the repairing establishments business continues fairly active, considering that at this period of the year repair work is usually scarce.

Engineering.—The Wallsend Slipway and Engineering Co., Limited, have, we understand, received the order to supply the engines and boilers (six in number) for the big vessel ordered by Messrs. Elder, Dempster & Co., from Messrs. Swan & Hunter, and it is understood that they have also booked further important orders for ice-breaker machinery. The remarkable success of the great ice-breaking vessel *Ermack*, built by Messrs. Armstrong, Whitworth & Co., and engined by the Wallsend Slipway Co., has given rise to the expectation that many more such vessels would be ordered on the Tyne; and it is satisfactory to be able to state that an order for a small one has been placed lately, and that negotiations for even a larger one than the *Ermack* are understood to be now in progress. The Slipway Co. have recently fitted the oil steamer *Cowrie*, owned by the Samuel Syndicate, with eleven burners (Rusden & Eeles's patent) for the consumption of liquid fuel, and this, we believe, is the sixth or seventh vessel that has been so fitted. An oil, which is said to be specially suitable for these burners, and which, being a residuum, is economically applicable, has been obtained from Borneo, where the supply, it is said is unlimited. The only difficulty apparently in the way of this oil being largely used is that of eliminating the admixture of water; but there is no reason to doubt that this difficulty will eventually be overcome, and the employment of liquid fuel in preference to coal, in oil steamers, may consequently be looked forward to with tolerable certainty.

A disastrous fire at the Elswick works has resulted in several hundred hands being temporarily thrown out of employment, the shops in which they worked having been destroyed, with all the machinery. As many as possible were put to work in other departments within a day or two of the occurrence; but it is feared that a considerable number will have to postpone their return to employment till the new shops, which are already in course of erection, are completed.

Both the engineering and the electrical works of Messrs. Clark, Chapman & Co., Gateshead, are very busy, and at the establishment of Messrs. Chapman & Furneaux (Black & Hawthorn's successors) considerable activity exists. The demand for Messrs. Carrick & Wardale's well known pumps for steamships is not only maintained, but is steadily developing, with the result that a further accession of activity is noticeable in the works. At Messrs. Abbots's, an extension of the boiler shop is being carried out, with a view to increase the productive capacity of that department, and in the arrangements of the iron foundries improvements are also being effected.

Messrs. Noble & Lund, of the machine tool works, Felling, continue to experience a good demand for their specialities, amongst which their special band saws, now so largely used in engineering works for cutting through cold iron or steel substances, should perhaps, have prominence. In the department where Mudd's patent piston rings are manufactured considerable briskness is to be noticed, and in the foundry departments activity also prevails.

Messrs. Robert Stephenson & Co., South Street, Newcastle, are well supplied with orders for marine and locomotive engines, and are exceptionally busy with the manufacture of a patent oil-engine, of which they have made a speciality.

The works of Messrs. Ernest Scott & Mountain—both electrical and engineering—show fully sustained activity, the orders for ship's pumps (Admiralty pattern) being numerous, whilst there is also a good amount of ship electric lighting in hand. Steelworks at Jarrow and Elswick are busy, whilst the small iron-rolling mills that still exist on the upper reaches of the Tyne are kept in steady operation. Forges, generally, are brisk, and there are few iron or brass foundries in the district that are not as full of work as could be desired.

Mr. W. F. Snowdon, of No. 2 Side, has had a great many contracts in hand this month for the covering of steamers' boilers. The demand for Snowdon's patent removable mattresses (for boiler covering) is steadily on the increase.

THE WEAR.

(From our own Correspondent.)

Shipbuilding.—In addition to the prospective opening out of shipbuilding and repairing works by Messrs. Short Brothers, at Seaham Harbour, we are now enabled to state that it is the intention of that firm shortly to utilise for shipbuilding purposes the yard to the east of their present establishment, which was acquired by them two or three years ago, but has, as yet, only been used for storage and fitting-out purposes. The opening out of this latter yard for shipbuilding is, we believe, contingent on the realisation of a scheme which has just been entered on, namely, the amalgamation of the iron (or steel) shipwrights with the wood shipwrights. The connection of this question with the prospective opening of the yard is that the alliance mentioned would ensure to Messrs. Short Brothers an adequate supply of capable workmen under any circumstances that might arise. It should be explained that Messrs. Short Brothers have always held themselves free from the domination of the Boilermakers' Society, which organisation rules paramount in practically all the other shipbuilding yards of the kingdom, and have depended exclusively upon the Shipwright Ironworkers, whose numbers are limited. The alliance of the two sections of shipwrights is all that is wanted to make the supply of workmen in the iron departments equal to all requirements, for it is well known, that the wood shipwrights (especially the younger men) can turn to the iron work with great facility. It may be mentioned here that a number of riveters left Messrs. Short Brothers a couple of weeks ago for the purpose of joining the Boilermakers Society. The general secretary of the latter organisation has since described the action of Mr. Short in paying off those men, as "high-handed." The real facts were that the men referred to were trying to induce the other workers to make common cause with themselves, with a view to force upon Messrs. Short Brothers acceptance of the Boilermakers' control or the alternative of having the yard laid idle. Mr. Short, as soon as he became aware of what was afloat, called the whole of the men together, and informed them that his firm would recognise only the Shipwright Ironworkers' Society in their yard, and that any men wishing to join the Boilermakers' Society (which would not be recognised) were at liberty to leave at once, and would be paid what was due to them before leaving. Since the departure of these men from the yard, their places have been filled by perfectly competent workmen, and the work has not been in the least degree impeded.

Messrs. W. Doxford & Sons continue very busy, and are now preparing to put down the big P. & O. boat ordered last year. At Sir James Laing's yard the state of work continues active, there being six vessels on the stocks. The extensive repair contract which has been in hand some weeks is nearly completed. The scheme of extension which has been entered upon at Messrs. Pickersgill's yard is of much greater scope than was originally supposed. The scheme involves the complete demolition of the existing machinery sheds, and the removal of the machines to a new shed which is being erected at right angles with the river. This will permit of the laying out of five berths, all running almost parallel with the stream, and capable of accomodating vessels of the largest class. The direction of the berths will give a launching way equal to that of any building berths in the yards at Sunderland or elsewhere. A quantity of new machinery is to be put down, and the general equipment of the yard will be brought thoroughly up to date.

In reference to the yards below bridge, little is to be recorded this month, excepting that all of them are still as busy as could be wished. At the yard of the Strand Shipbuilding Co., some trouble has been caused by the efforts of the Boilermakers' officials to induce the men (who like Short Brothers' men are Shipwright Ironworkers) to forfeit their allegiance to their employer, and to their own local union. They did not succeed, however, and it is scarcely likely that they will make any further attempts, considering the futility of their efforts on this occasion.

Both the large graving docks owned by the Wear Commissioners are occupied with vessels undergoing repair, and there is a good deal of repair work in hand at Messrs. Austin's and Messrs. J. L. Thompson's. In the ships' boat building trade only a moderate business is doing.

Engineering.—A new local company, named the Rectory Engineering Co., Limited, has been formed by a number of Sunderland gentlemen, to take over the old Rectory Engine Works, formerly (and until very recently) occupied by Messrs. J. G. Allison & Sons, in the manufacture of gas engines. A large number of the special type of engines made have been sold in the district as well as further afield, and their reputation for sound workmanship and economy in operation is excellent. It is the intention of the new company to continue the manufacture of gas engines, and also the business (previously carried on) of general repair work to gas and steam engines, millwrighting, &c. A portion of the works has been set apart and specially equipped for the manufacture of the Wilcox patent Radio-Mundal evaporators, feed-heaters, &c, for which there is a large and increasing demand. It needs only to be added that this new enterprise is being started under very favourable auspices, the company having some good orders already in progress, and expecting to have the works in full swing in the course of a few days. Mr. Percy Willcox has been appointed managing director, and Mr. Reginald Willcox, works manager.

We understand that Messrs. J. G. Moore, of the Vulcan Works, Church Street, Monkwearmouth, have leased an extensive piece of ground near the Strand Ferry, on which it is intended to build premises, better suited to their business than those they at present occupy. The firm also intend adding to their present business the manufacture of steering-gears, steam winches, &c., for the carrying out of which lines on an extensive scale the new premises (or rather a part of them) will be specially designed.

Messrs. MacColl & Pollock, of the Wreath Quay Engine Works, are fully supplied with orders to at least the end of the year, and still find it necessary, like all the big establishments, to keep a night shift going. New offices are being added to the works and will doubtless prove a great convenience.

Local ironworks are still very busily employed, and in the foundries full activity exists. At the Sunderland Forge business is as brisk as ever in both the electrical and engineering departments. Brass and copper works are busy, and in the manufacture of special types of anchors there is still a good deal doing.

The Hartlepools.—Shipbuilding is still active at the Hartlepool and West Hartlepool yards, and during the fine weather now prevailing, overtime is being largely worked by the outside hands. In the repairing departments work is active, there being some good contracts in hand. The engineering trade also continues brisk, and night-shift is maintained in the factories. Forges and foundries are kept going briskly, and timber importations having largely increased lately, a good demand for labour now exists at the docks.

Stockton.—Here also shipbuilding continues brisk, Messrs. *Ropner's being, perhaps, the busiest* yard in the district. In the *engineering works no signs of coming slackness* are as yet visible, and both bridge works and boiler works show as much activity as at any former period.

Middlesbrough.—All the berths in the yards at this centre are occupied with vessels building, and there is also a considerable amount of repair work in hand. Steelworks are still pressed with orders, and prices remain firm. At the docks business continues to improve, owing to the larger arrivals of timber-laden vessels.

Consett.—The pressure of work at the Consett Co.'s iron and steel-rolling mills is as great as ever, and everything possible is being done to further increase the output, which is now much larger than at any former time.

THE MERSEY.

(*From our own Correspondent.*)

ALTHOUGH the work in hand throughout this district, both in connection with shipbuilding and marine and general engineering, is more than sufficient to keep establishments fully engaged, and will in most cases carry them well into next year, there is unquestionably a slackening-off as regards new inquiries coming forward; and the question arises, in many quarters, whether the large and serious upward move in the price of all descriptions of material which has been going on during the past month may not tend to check the placing out of new orders. Certainly shipbuilding and engineering firms, in quoting for new work, will have to very considerably increase their prices in order to enable them to cover the very greatly enhanced cost of production; and whether trade is in a sufficiently "booming" condition to stand this rapid upward move in prices—which do not as yet seem to have touched the top—is a matter which only further developments during the ensuing six months can determine with any definiteness.

The returns issued by the leading trade unions still show a very low unemployed list. The Amalgamated Society of Engineers has only 2⅓ per cent. of its total membership on out-of-work donation, whilst in this immediate district the proportion is just under 3 per cent. In the Steam Engine Makers' Society there is about 1 per cent. of the total membership on benefit, but, locally, practically a "clear book" is reported. The United Machine Workers' Association has a trifle under 2 per cent. of its total membership on donation, with about 1⅓ per cent. receiving support in the Lancashire district. Reports as to the state of trade continue very satisfactory. In the Amalgamated Society of Engineers only 15 out of over 520 branches in the United Kingdom report trade as "bad," and in the other societies the proportion is even less. With regard to labour matters, an adjourned conference is to take place at an early date with reference to the wages question in mid-Lancashire. At Liverpool a demand from the men for a general advance has been met with a point-blank refusal, coupled, however, with a hint that if the workmen are not satisfied, they can appeal to the central authority.

Messrs. Holden & Brooke, Limited, West Gorton, Manchester have brought out a new form of exhaust steam-injector (Brooke's patent), specially designed for feeding against high pressures, such as 180 to 200 lbs. This apparatus is a combination of two injectors—one, the larger, worked by exhaust, and the other by live steam. The exhaust portion is operated in the usual way by a branch direct from the exhaust pipe, and the highly heated water thus obtained is forced direct into the second, or "supplementary," injector, whence, by the aid of a small jet of live steam, it is forced into the boiler. Live steam is turned on immediately the exhaust-injector has been started (which in the meantime discharges through an overflow cock on the side of the supplementary injector) by raising a lever, which simultaneously closes the overflow, by which time the injector is delivering into the boiler. It is claimed that by this arrangement, whilst the economy due to the use of exhaust steam remains unaltered, there is a further economy arising from the use of the live steam jet, owing to the fact that every increase in the temperature of the feed water, even if obtained solely by live steam, has marked advantages over feed of a lower temperature, both as regards steaming capacity and the life of the boiler. The temperature at which the injector delivers its feed ranges from 235 to 270 degrees Fahr. The apparatus has been severely tested at important locomotive and engineering works, against 200 lbs. pressure, with very satisfactory results.

A new apparatus (Baker's patent) for softening and purifying water for steam-raising and other requirements has been introduced by Messrs. D. Bridge & Co., Salford, Manchester. In this arrangement the water is blown into the upper part of the apparatus in spray, and there met by steam in such proportion that the water boils, and at this stage a small quantity of calcide solution is introduced. The heated water and calcide pass down several concave and conical surfaces in the heater, becoming thoroughly mixed, and the lime with other impurities at once separates from the liquid in heavy insoluble particles, the greater part of which at once falls to the bottom of the first of three compartments of a depositing tank; the clear softened water from the top of the first compartment then passes to the bottom of the second, and from that to the third, whence it finally passes out through a suction pipe to the boiler feed pump, or elsewhere as required.

Messrs. J. Stott & Co., of the Vernon Works, Oldham, have a number of new designs in ventilating, lighting, and heating appliances. Amongst these is the "Stott" water-fan, which is specially serviceable for ventilating purposes where water is available and more convenient to apply than any other power. The water is admitted through a pipe at the top of the fan, and is applied through a modified form of the Pelton wheel, which is introduced in the ring of the fan, and connected with the revolving blades. Another new apparatus is a patent acetylene-gas generator, which is an automatic arrangement on the duplicate system, whereby one chamber can be cleared and renewed whilst the other is at work, without stopping the supply of gas. The apparatus is also fitted with patent cooling pipes, the effect of which is that the gas feeds into the holders at the same temperature as that of the outside air. The firm have also brought out an improved form of the Ballantine-Stott patent water-heater, in which the steam and the water valves are both operated at the same time, and the temperature of the heated water is regulated to a maximum of 110 degs., so that there is no danger of the user becoming scalded.

On June 3rd the members of the Manchester Association of Engineers paid a visit to the works of Messrs. Joseph Adamson & Co., at Hyde. These works are specially interesting as affording a good illustration of the most modern equipment for electric-power driving, the majority of the machines in the establishment being driven in this manner, whilst there are further interesting features in connection with the arrangements that have been made for saving labour in the handling of materials. Amongst the work in progress attention was paid to two steel-plate fly-wheels, 24 ft. diameter, each weighing 45 tons, which were being built for Messrs. Cole, Marchant & Morley; also a 50-ton travelling crane 62 ft. span for Messrs. C. Cammell & Co., Limited, Sheffield; and in contrast with this a smaller crane to deal with loads of five tons, on a span of 40 ft., for the Earl of Dudley's Round Oak Works Co., Limited, Brierley Hill, Staffordshire. Before leaving the works, the president of the association, Mr. Henry Webb, moved a vote of thanks to the firm for their kindness in allowing the members to visit the establishment, and Mr. Joseph Adamson, in responding, remarked that they could not expect workmen to produce the best work except in a clean, bright, and well-organised shop.

The upward move in prices in the iron trade here, which has been reported for some months past, still goes on without any check either as regards raw or manufactured material. The business doing is of no great weight, but it is more than makers and manufacturers can entertain. In pig-iron, prices have advanced 6s. to 9s. per ton during the month. For local and district brands makers have generally little or nothing to offer, and for the most part are declining to quote at all, except for small quantities to keep their regular customers going. The prices now asked average about 67s. 6d., less 2½ for Lancashire, 65s. 6d. net for Lincolnshire, and about 67s. for Derbyshire foundry, delivered Manchester; with forge qualities delivered Warrington, not quoted under 65s. to 65s. 6d., less 2½ for Lancashire, and 64s. 2d. net cash for Lincolnshire. Middlesbrough foundry has shown an upward move of fully 9s. per ton, and good foundry qualities are now quoted 73s. 7d. net, delivered Manchester, with orders exceedingly difficult to place; whilst Scotch iron is about 4s. higher, makers asking 72s. for Eglinton and Glengarnock, delivered Manchester Docks. For American pig-iron about 64s. net at docks has been quoted, but at the time of writing no prices are obtainable.

In the finished-iron trade there has been a further official advance in list rates, bars and hoops having been put up 10s., and merchants' stock prices have also been raised 10s. per ton. This upward move has apparently put no appreciable check upon business. Delivered Manchester district, Lancashire bars are now quoted £7 15s., and North Staffordshire £8, with hoops £8 2s. 6d. for random to £8 7s. 6d. for special cut lengths, delivered Manchester district, with 2s. 6d. less for shipment. Sheets have also hardened up about 5s. per ton, £8 12s. 6d. to £8 15s. being now quoted for delivery here.

Prices in the steel trade have shown some irregularity, raw material having advanced 7s. to 10s. per ton, whilst in manufactured material the upward move has been chiefly confined to special brands. Hematites are now 79s, with special brands 82s. to 82s. 6d., less 2½, and local billets £5 17s. 6d. net. Local steel bars are £7 15s., with some special brands, £8, whilst boiler plates range from £8 15s. to £9; hoops have been officially raised 15s. per ton, £8 10s. being now the basis for delivery in this district.

There is no material change to note as regards the metal market, manufacturers being pressed with orders, and prices firm at late list rates. Delivered Manchester district, solid-drawn brass boiler-tubes are quoted 9d.; solid-drawn brass surface-condenser tubes 10½d.; solid-drawn copper tubes 11¼d; brazed copper gas and steam tubes 11¼d; brazed brass tubes 10d.; common rolled brass 8¾d; common brass wire 8½d; copper wire 10¼d. per lb.

Business in the timber trade has been fairly satisfactory The new season's imports are now coming forward and meet with a tolerably good enquiry; stocks generally are not excessive and prices, except for a few articles, are firm. Teak squares have arrived more freely and have been chiefly stored for shippers' account; there is a fair demand, and prices are steady, with stocks moderate. Planks continue in good demand, with values maintained, and stocks are not excessive. One cargo of greenheart has arrived from Demerara, and a parcel of large average logs transhipped from Middelburg, which has gone direct into consumption; the demand has been moderate, but stocks are too heavy.

In the coal trade there has necessarily been a considerable falling off in requirements for house fire consumption, but pits have generally been kept on full time, and any surplus output of the better qualities of round coal is required to go into stock to meet the ensuing winter demand. Prices for house coals are firm at late rates, and contracts with merchants are only being accepted at present full prices, subject to any further advance that may take place during the period of delivery. Steam and forge coals are in active request, with prices hardening on late quotations. Engine fuel is in brisk demand, and the better sorts continue scarce, and very firm in price, but the lower descriptions are somewhat more plentiful, and not quite so strong at late full rates. At the pit's-mouth best Wigan Arley averages 12s. to 12s. 6d.; Pemberton 4 ft. and seconds Arley, 10s. 6d. to 11s.; common house coal, 9s. 6d. to 10s.; steam and forge coal, 9s. to 9s. 6d.; engine fuel, from 4s. 9d. to 5s. 3d. for common, 5s. 6d. to 6s. for medium, and 6s. 6d. to 6s. 9d. for best sorts. Coke is becoming increasingly scarce, and prices show a continued upward move, ordinary furnace qualities fetching 18s. to 19s., and good foundry qualities from 24s. to 26s at the ovens.

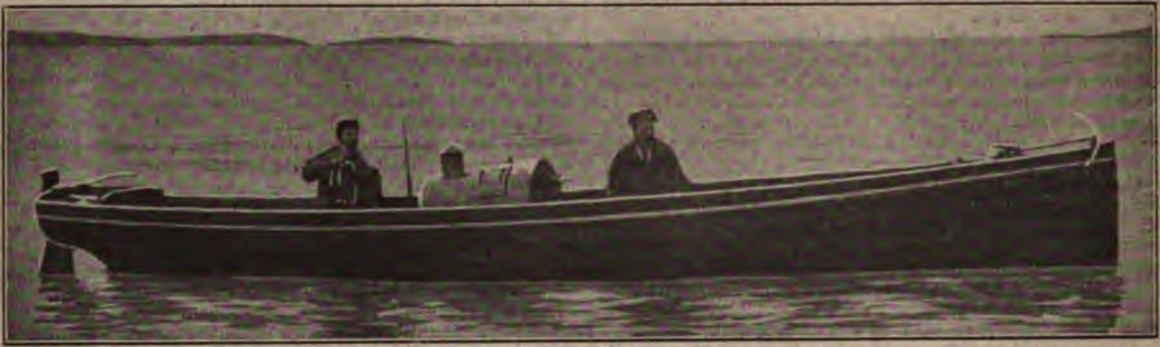
There is a fairly active shipping business, but prices are without quotable change, ordinary steam coals, delivered Garston Docks, fetching about 9s. 6d. to 9s. 9d.; delivered high level, Liverpool, 10s.; and Ship Canal, 10s. 6d. per ton.

THAMES.

(*From our own Correspondent.*)

THE *Marine Engineering*, of New York, gives first place to an article on the *Farragut*, the first American torpedo-boat destroyer, which has just been completed, and recently underwent her trials. She was built by the Union Ironworks, and launched on July 16th, 1898. Her dimensions are 214 ft. over all, beam 20 ft.; draught, 5 ft. 7 in.; and trial displacement, 240 tons. She is fitted with twin-screw engines of the four-cylinder four-crank triple-expansion type, with cylinders 20 in., 29 in., and two 30 in. diameter, and 18 in. stroke. The air pumps are drawn direct from the crank shafts. The boilers are three in number, and of the Thornycroft type, each rated at 2,000 H.P, with 240 lbs. pressure. These boilers of the *Farragut* were built in the United States under licence from Messrs. John I. Thornycroft. There will soon be tried the skill of this firm in racing yacht building. In our Electrical columns will be found a reference to M. Marconi preparing to fit his system of wireless telegraphy to record the international race. This country will be represented by the *Shamrock*, which is now undergoing her internal fittings. It will then be seen whether American or English builders are the better.

Messrs. Tolch & Co., of Fulham, have under construction two 35 ft. oil launches for the Government Coast Guard service. They have also built a harbour boat of whale-boat shape. The name of this boat is the *Muriel Dora*. She is 30 ft., 7 ft. 6 in. beam, and carries three tons. Her engines are double cylinder, 6 B. H.P. She is to be used for going round the light buoys in the harbour. They have also built a launch for the War Office Submarine Mine service (Fig. 1). Her dimensions are 67 ft., 15 ft. beam, and 8 ft. 3 in. depth. Her engines are double-cylinder, and 15 H.P., and she makes seven knots an hour. They are at present engaged with two for the Thames yachtsmen.



Teak Launch, Copper-Sheathed, with 5 B.H.P. Balanced Engines, War Office, Submarine Mining, Weymouth.
Fig. 1.

The Belleville Again.—Mr. William Allan has had a little Belleville boiler made to scale, of which the tubes are glass. This enables one to see the circulation of water, and whether the tubes are always full of water, or sometimes water and steam, or sometimes steam alone. Mr. Allan went further than that, for he took his model with the glass tubes to the smoking-room of the House of Commons, and there made it work before a number of interested members of Parliament Mr. Allan argues that the tubes are often mostly full of steam, and that this is due to defective circulation. A number of articles have been appearing in the *Pall Mall Gazette* on the same subject, only the writer in the evening paper is not so discriminating as Mr. Allan—he writes against all water-tube boilers. Mr. Milton and inspectors of the Board of Trade are quoted very indiscriminately, and there are other people brought in whose opinion is not of very great value. But the Admiralty will probably, and very wisely, go on its own way all the same. We have always had a preference for the express type of water-tube boilers, and it must be confessed that the working condition in the stoke-hold of a destroyer, even when she is running at her highest speed out is very excellent and comfortable. As far as we can see, these boilers are making way in the navies of other Governments. It will be seen above that the Thornycroft style of boiler has been fitted into the first destroyer constructed for the States.

Messrs. Yarrow & Co. are also fitting their type with modifications to suit the different conditions. Not less than six cruisers of 10,000 H.P. each have been fitted, or are about to be fitted, with these boilers. There are also two battleships of 6,000 H.P. each to be fitted with them. The ordinary Yarrow express type of boilers has tubes 1 in. diameter, whilst the modified boiler of this type has tubes 1¼ in. diameter, and they are stronger and thicker in every part. Then again, the heating surface is increased per I.H.P. In the express type 2 ft. are allowed per I.H.P.; in these larger boilers, suitable for battleships, the allowance is 2½ square feet of heating surface per I.H.P. The draught pressure also is reduced from 2½ in or 3 in. of water to from 1 in to 15 in. of water. The capacity of these water-tube boilers is greatly *increased. Four boilers* are used in the Japanese destroyer, *giving an aggregate steaming capacity of* 6,500 H.P. with 1½ in. air pressure in the stoke-hold. The total weight of the fire boilers with water is 72 tons, that is, 25 lbs. per I.H.P. Messrs. Yarrow are also fitting a Portuguese cruiser of 12,700 I.H.P. with 12 Yarrow boilers, and two Norwegian ironclads are also being fitted at Elswick with the same type.

The Pyrometers which have in the past been used by engineers for furnace temperature have not been very reliable. That which has been invented, constructed, and tried by Professor Callendar, of University College, London, appears to be a very sensitive and reliable instrument. It consists of a Wheatstone bridge, the slider is automatically effected by relays worked by the current passing through the galvanometer between the bridge arms. There is also a platinum thermometer to work with it. It consists, says *Engineering*, of a coil of platinum wire insulated by being wound on a frame of mica. The ends of this wire are soldered to two copper or platinum leads, which connect it to two of the four terminals with which the instrument is provided. The increase of the resistance of this platinum coil with rise of temperature is of course a measure of that temperature; and, should the thermometer form part of a Wheatstone bridge, the balance of the latter will be disturbed, and when the instrument is connected to the recorder, this balance is readjusted automatically. These thermometers can be made to indicate the one-thousandth of one deg. Cent. and determine temperature down to the freezing point of platinum. The resistance of the platinum coil is a parabolic function of its temperature, and the standardisation of the instrument is easy. At the conversazione of the Royal Society, held on May 3rd last, four of the recorders were on exhibition. One was fitted up as a sunshine recorder; a second as an automatic temperature regulator, maintaining a gas furnace at a constant temperature of 1,000 deg. Cent. within ½ deg. Cent. of absolute steadiness; a third was used as a thermo-electric pyrometer, measuring the temperature of a Bunsen flame; whilst the fourth acted as a recording watt-meter.

Caird & Rayner having been trying a new system of working with steam used in ships of war. Instead of exhausting the steam from the low-pressure cylinder into the condenser the pressure of steam is raised by steps throughout the system and exhausted finally into the evaporators. One of the ships so fitted is H.M.S. *Hermes*, and she was on trial off Plymouth on May 29th. At the conclusion of the trial the mean I.H.P. was found to have been 2,099. The boiler pressure was 203 lbs., which was reduced to 157 lbs. at the engines. With the above power, which was 99 I.H.P. above the one-fifth full power, she attained 13·4 knots. The exhaust produced all the feed water required. Sir John Durston is still making experiments on the effect of high-pressure steam in the jackets of the cylinders. When the above trials were finished, she was sent on a 12 hours' duration trial at 1,000 I.H.P. one-tenth full power. During the first four hours the jackets were used on all cylinders; in the second four hours they were only used in the low-pressure cylinders, and in the third four hours they were not used at all. In the 30 hours contract trial the same requirements were made, the 30 hours being divided into three periods of ten hours each.

Messrs. John Penn & Sons, one of the very oldest marine engineering firms in the country, is going to lose its name, as it is being taken over by the Thames Limited Co., across the water. The ships will still be built at the old place and the engines at what has been known for the last century as John Penn & Sons, Mr. Hills, of the Thames Limited, is the head of the joint firm, and application was made this week in court to allow the name to be changed. They have jointly begun well. The two battleships *Duncan* and *Cornwallis* will keep them busy for the next two or three years. The engines and boilers for the battleships are to be constructed at the new department of the firm. The engines are to be built on the system in vogue at the Admiralty at present—one high-pressure, an intermediate, and two low-pressure cylinders; they are twin engines for twin screws. The dimensions of the cylinders are to be 33½ in. high pressure, 54½ in. intermediate-pressure, and two 63 in. low-pressure, with 4 ft. stroke. They will probably exhaust into the evaporators. Each battleship is to be fitted with 24 Belleville boilers with economisers, the pressure in the boiler being 300 lbs., and this is reduced by the reducing valve to 250 lbs. A great amount of new machine tools and plant for the construction of the boilers is being laid down, and new shops are being laid out and built for the construction of these boilers at the old place at Greenwich and not at Deptford, where the Blechynden boilers and cylindrical boilers were built. The Blechynden boilers fitted into the third-class cruisers *Pactolus* and *Pomone* are giving every satisfaction, no complaints or burst tubes have been heard of. The *Pactolus* has been up the Mediterranean. Each of these third-class cruisers was designed to develop 7,000 I.H.P., and eight Blechynden boilers were fitted into each vessel for this purpose. The thickness of the tubes was 11·6 in. for the express type of Blechynden boiler and the thickness of the tubes for the Belleville is to be 192 in.

BELFAST.

(*From our own Correspondent.*)

WE have nothing during the month to report in the matter of launches. We have seldom if ever had so few launches in the early months of the year, and indeed unless there is a great deal more work done shortly, the finished tonnage will fall short of previous years, but, as mentioned in our last report, the main cause of this is the scarcity of ironworkers and material.

Both the large shipbuilding firms here are involved in the failure of the largest Glasgow iron merchants, and this has seriously handicapped them in delivery, and in having to re-order material at an enormous advance in price, causing unforeseen delays in the output of work, which we are afraid cannot be overtaken during the remaining months of the year, although there is certainly abundance of work on hand with the enormous amount of tonnage still surrounding the yard of Messrs. Harland & Wolff.

At the adjacent docks we have still the *Oceanic*, which occupies a large space in herself. She is fast advancing towards completion, and had a most satisfactory turn of her engines, one engine at a time being run, and that very slowly and cautiously, the ship being moored at a distance from the wharf.

The event of the month has been the docking of the P. & O. steamer *China*. As is well known, this vessel after being floated off the rocks at Perim at an enormous expense, came to Belfast about two months ago under her own steam, accompanied by two powerful tugs. Prior to docking her the boilers and funnels, the foremast, and all the top gear were removed, as little idea could be formed as to the extent of damage to her bottom. The plan was resolved on of hanging the upper part of the vessel by cutting large square holes in her sides below the structural framework of the upper decks; through these holes large heavy logs of timber were inserted athwartships, shored and braced to the beams internally, but the ends of the logs on each side projecting so far out as to enable a heavy log shore to be put upright from the bottom of the dock to the underside of crossbeams. This work required very careful measurement and study, as these shores had all to be placed in position, while the vessel was afloat in dry dock. Notwithstanding all these details, the docking operation only occupied six hours, which, after seeing the work that has been done, was really a feat in itself. On the dock being pumped dry, a great sight was presented to view, one part of the keel was set upright about eight feet from the straight line upwards, with the plates and frames in every conceivable shape of indents and twists which the rocks had made while she lay fast at Perim. Notwithstanding this very few of the plates were cracked, or the rivets started, but where they were broken they had been most ingeniously patched with wood and cement by the divers under water. Then again another difficulty had to be faced. With the enormous quantity of cement used to make the ship watertight, how was the mass to be removed? Finally it was decided to use dynamite, and with this the whole of the fractured part of the bottom has been blown off in pieces, and now, after the wreckage being cleared away, the work of reconstruction has begun, and no doubt she will be as good as a new ship when she is finished. But it is really an interesting and novel sight to see such a large ship hung up by her upper structure, and her bottom part cut clean away, with the new structure rising to meet the old.

The s.s. *Germanic*, of the White Star Line, has been in the hands of the builders, Messrs. Harland & Wolff, for some months, getting an extensive overhaul after the extraordinary accident which befell her last winter in New York Harbour. The mishap destroyed most of her internal fittings, so all the woodwork and decorations have been removed, and have been replaced by an entirely new design of saloon, library, and smoking-room, along with all the latest improvements of the company. She left Belfast on the third of the month for Liverpool, with a select company of owners and friends on board, and has since sailed for New York in her regular station.

The s.s. *Medic* and s.s. *Afric*, both of the White Star Line, lie in Abercorn Basin, with a large number of men on board each of them; and the s.s. *Belgic*, of the same line, has also arrived at the Alexandria Wharf, it is said, to receive overhaul and new boilers.

The s.s. *Winifredian* is still here in port, and has a good deal of work to be done before being completed.

The s.s. *Cambronian*, of the Dominion Line, is also here receiving alterations and overhaul, and the s.s. *Sandusky*, now named the *Englishman*, which has been purchased by the Dominion Line, is also here for requisite fitting similar to her sister ship, and suitable for the Atlantic trade.

The s.s. *Gaekwar*, belonging to the Brocklebank Line, which arrived at this port over a week ago, after being ashore at Tiree on the Scotch coast, has had to leave this port and proceed to Liverpool, on account of want of accommodation of dry dock, the Alexandria Dock being occupied by the *China*, and the Hamilton Dock by a large sailing ship. Surely this should open the eyes of those concerned in this matter.

Trade with the smaller engineers and ironfounders throughout the town still keeps good, but there is undoubtedly a falling off in inquiries for new work all round. Let us hope this may only be temporary.

NORTH-WEST OF ENGLAND.

(*From our own Correspondent.*)

Barrow.—The shipbuilding trade of Barrow is very brisk in every department, and builders remain exceedingly busy all round. There is not, however, a very good demand for new commercial tonnage, possibly because the recent orders placed represent a very large tonnage of new shipping, and secondly because the cost of building, with increased cost of raw material and increased wages, is almost prohibitive. At the same time some of the best lines are in the market, and it is probable before long they will place good orders in various yards throughout the country for the highest class of vessels. On the other hand, it is evident that in these days of brisk shipping business owners of tonnage will increase the number of ships engaged in the general cargo trades. The tendency in this regard is to build ships of very large tonnage for the ocean trade; and, whilst it is not probable that the common tramp class of steamers will ever be built at the Barrow yard, it is possible some of the biggest cargo boats may be built here, because the yard is one capable of building the very largest ships ever launched or yet to be launched, and the docks at Barrow have wide enough entrances and deep enough water to float either the biggest commercial steamer or the heaviest mounted line of battleship. In the meantime, with the exception of the Pacific Steam Navigation Co.'s steamer *Ortona* now building, and a trifling job for one of the Clan Line steamers, there are no commercial orders in the hands of Messrs. Vickers, Sons & Maxim. They are setting the Naval Construction Works out especially for the production of Admiralty ships, and they are likely to do a very big business in this department, but they would not refuse good orders for high-class commercial ships, indeed they are ready to accept orders for the best type of tonnage any day. The launch of the s.s. Bornu, for the West African Steamship Co., enabled

Messrs. Vickers to put down the keel of the first-class protected cruiser *Euryalus*, and when the *Ortona* is launched on the 10th of this month (July), her place will be taken by the new first-class protected cruiser *King Alfred*, one of the improved *Powerfuls*. When H.M.S. *Vengeance* is launched on the 25th of July her ways will be ready for any new order for a big ship that may turn up, and the fact that the *King Alfred* is not going down on these ways is proof that some other big order is in the air. It is anticipated that Barrow will play a more active part in the future in building for foreign navies than in the past. At present the only ship under construction for a foreign navy at Barrow is a Japan line of battleship of 15,000 tons, but the works have not been under the control of Messrs. Vickers long enough a time to enable them to carry out the full scheme of extensions which they contemplate, and which will be necessary to enable them to tackle the fuller programme of industrial operations that their large naval shipbuilding scheme embraces. This is a difficulty which time alone can get over, and in the meantime every effort is being made to complete extensions to premises, lay down new and modern machinery, build new departments, and extend the yard area so as to make the concern at any rate double the size it was when taken over from the Naval Construction & Armaments Co. In addition to the new departments already determined on in the yard, a new iron foundry, steel foundry, brass foundry, and copper shop are being added to the premises. There is still a great scarcity of houses for workmen, and, although a scheme is on foot for providing 1,000 to 1,200 houses on Walney Island, it is evident some special accommodation will be needed in the meantime to house the large number of men who are required to push forward the orders in hand at the Barrow works. The West African Steamship Co.'s *Bornu* had her trial trip from Barrow to Liverpool, in the first week of June, and it was in every respect highly successful. It is understood the company is anxious to place out orders for further additions to their fleet, but Barrow builders are too busy at present to undertake any other work than that which is in hand and that which is in perspective. During the month the carpenters struck work at the Barrow yard because the joiners were put on to do some insulating casing on one of the Admiralty ships in course of construction, The carpenters claimed this as their job, and the joiners persisted in doing the work. After the carpenters had been on strike a few days, however, they decided to submit the dispute to arbitration, and to go on with their work meanwhile, the joiners in the meantime to proceed with the casing about which the dispute arose. There is a growing disposition at Barrow to settle all disputes by means of arbitration, The usefulness of gantries over shipways when vessels are in course of construction has been so thoroughly demonstrated that it has been decided at the Barrow yard to adopt this principle at the permanent shipways. There is no doubt great economy in this practice, and it doubtless affords means for the more expeditious building of ships. The Furness Railway Co.'s Bill to obtain powers to build a new graving dock and lock at Barrow, and for other purposes, has practically passed through its Parliamentary stages. In the first place, however, the Company will not proceed to build this dock, but will commence operations for the lowering of the cill of the lock entering the Ramsden dock by 6 ft. This will enable big warships and other vessels of 30 ft. draught and 80 ft. broad to get in and out of the docks at Barrow. This is necessary, because the vessels have to go through the docks to the big hydraulic crane alongside the engine shops and boiler shops where they take in their engines and general fittings, and the larger tonnage of vessels now being constructed at Barrow necessitates this extra depth of water. The 100-ton hydraulic crane has now been fixed up to lift 120 tons, and some of the marine boilers now built approximate to this figure.

West Cumberland.—The shipbuilding business in West Cumberland is very busily employed, and the two yards at Workington and at Maryport are well off for orders. At Messrs. R. Williamson & Son's shipyard, Workington, on May 30th a new steamship, the *Formby*, was launched for Messrs. J. Edwards & Co., Liverpool. She is 152 ft. long, 26 ft. 6 in. beam, and depth, moulded, 12 ft. 3 in. She is designed to carry 520 tons. She will be engined by Messrs. Ross & Duncan, Govan. It is in the building of this small class of steamer, that West Cumberland shipbuilders find their trade, and orders for various types of light draught vessels are in hand as well at Workington as at Maryport. Some day, it is hoped, engineering works will be established in West Cumberland to supply locally built steamers with engines and boilers complete.

Shipbuilding Material.—There is a very full and steady demand for steel shipbuilding material in this district, and makers are very fully employed in the production of heavy and light steel plates, angles, sections, and other incidentals required in ship construction. Some apprehension was felt a short time ago that the falling-off in the demand for mercantile marine tonnage would lead to a lessened demand for shipbuilding material all round, and especially so after Christmas of the present year. Up to that time orders are very largely held as well for Admiralty work as for the mercantile marine. It is evident there will be a continued demand on Admiralty account after this year, because orders are held by builders which will keep their yards fully employed for two years to come, and in the meantime makers continue to book occasional orders for commercial work. It is probable this trade will grow, because there is no foreign competition fit to speak of in the shipbuilding material trade whereby British makers may expect to lose any of their present business, and on the other hand there is every indication that our foreign trade may profit by the general briskness of things abroad. Makers quote £7 6s. 3d. for plates of ordinary specification, and £6 18s. 6d. for angles. Very few angles are being made in this district, but it is probable a new mill will soon be put down. The steel foundries are very busy. Their capacity of output has recently been increased, and will likely have to be still further augmented, as the trade doing is so very great and is likely to remain so.

The Hematite Trade.—There is a very brisk tone in the hematite pig-iron trade, and business is very fully maintained; indeed, makers could readily sell the product of six more furnaces if they could possibly keep more than 42 in blast on the supplies of raw material at command. The product of these furnaces represents a million and a half tons of iron per year. Prices are very firm, and show a distinct advance on the month. Makers quote 72s. to 73s. per ton net f.o.b. for mixed Bessemer numbers, and warrant sellers are at 72s. 2½d. net cash; buyers, 71s. 8d. Stocks have slightly increased, and now stand at 232,057 tons, or 56,078 tons increase since Christmas of last year. The prospects of the iron trade are very good all round.

Shipping.—The shipping trade is fairly busy at West Coast ports, being chiefly employed in imports of Spanish ore and American and other timber and in the export of pig-iron and steel. The returns so far this year show a marked improvement in imports, the figures making up a record tonnage. Of pig-iron this year so far 236,295 tons have been exported as well as 229,269 tons of steel. In the corresponding period of last year 235,589 tons of pig-iron and 262,773 tons of steel were exported, showing an increase this year of 706 tons of pig-iron and a decrease of 33,504 tons of steel. Freights are very satisfactory, and there is a good demand for shipping tonnage generally, foreign as well as coastwise.

SOME INTERESTING DIAGRAMS FROM TRIPLE-EXPANSION ENGINES.

WE have received from one of our correspondents in the East some extremely interesting diagrams relative to a set of triple-expansion engines of a steamer running in the Eastern waters. The engines have cylinders 19 in., 33 in., and 54 in. diameter by 33 in. stroke, and the pressure of steam is 100 lbs. per square inch. It was found that the engines were not working as satisfactory as might be expected, and in consequence the theoretical diagrams, as shown in Fig. 1, were set out. From these diagrams the necessary particulars were obtained to reconstruct and reset the valves. In Fig. 2 we show the actual diagrams after the alteration.

In the theoretical diagrams it was estimated that at 94 revolutions per minute the I.H.P. would be about 1,250. The actual diagrams show, although with adverse wind and tide, and at 95 revolutions per minute, a total H.P. of 1,091 was obtained. The pressure in the mid-pressure receiver was 66 lbs., and in the low-pressure 12½ lbs. per square inch. The high-pressure engine gave 280 H.P., the mid-pressure 406, and the low-pressure 405.

In the matter of coal, which was of inferior quality, it was found that the consumption was at the rate of 1·9 lb. per H.P. per hour, which is equivalent to 1·6 or 1·7 lb. with Welsh coal. The amount of water used per I.H.P. per hour was 15·8 lbs. It is a matter of considerable interest to note the close approximation of the theoretical and actual results to one another, the beauty of the lines and clearness of cut-offs in the actual

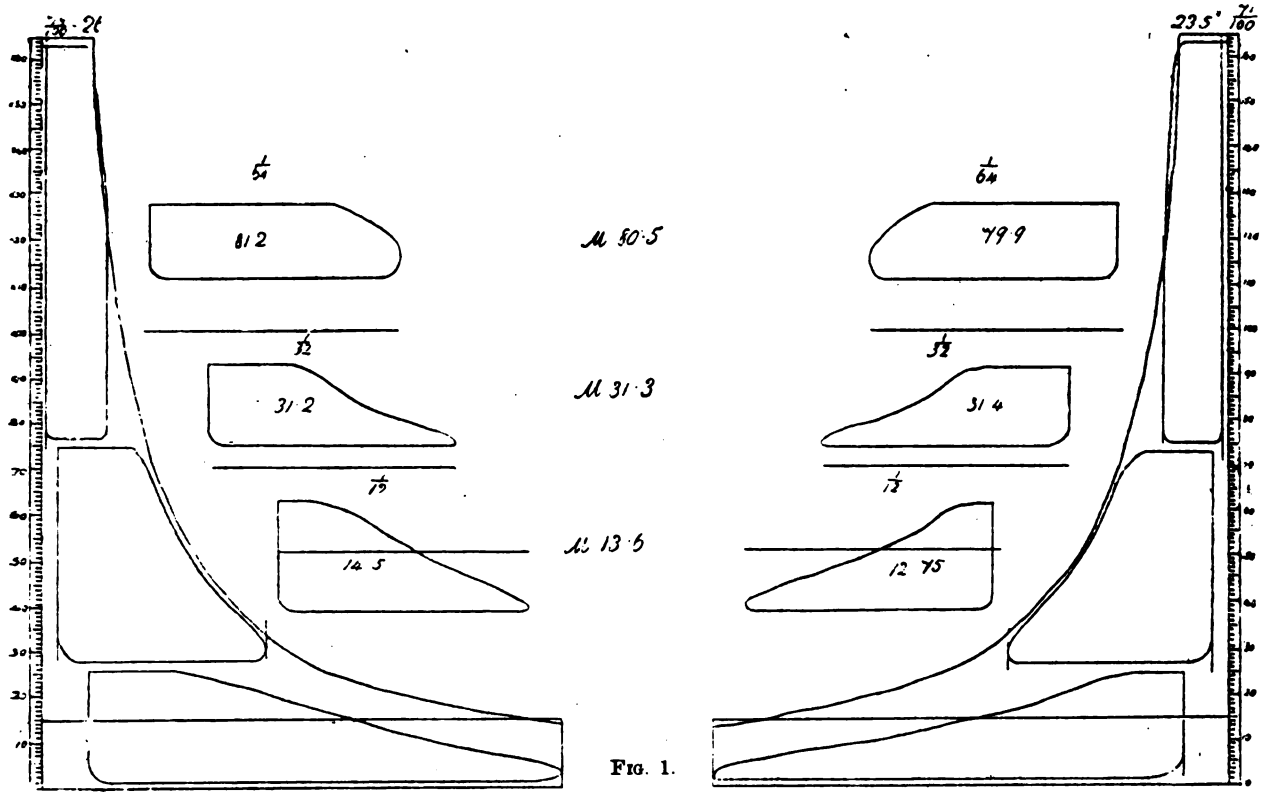


Fig. 1.

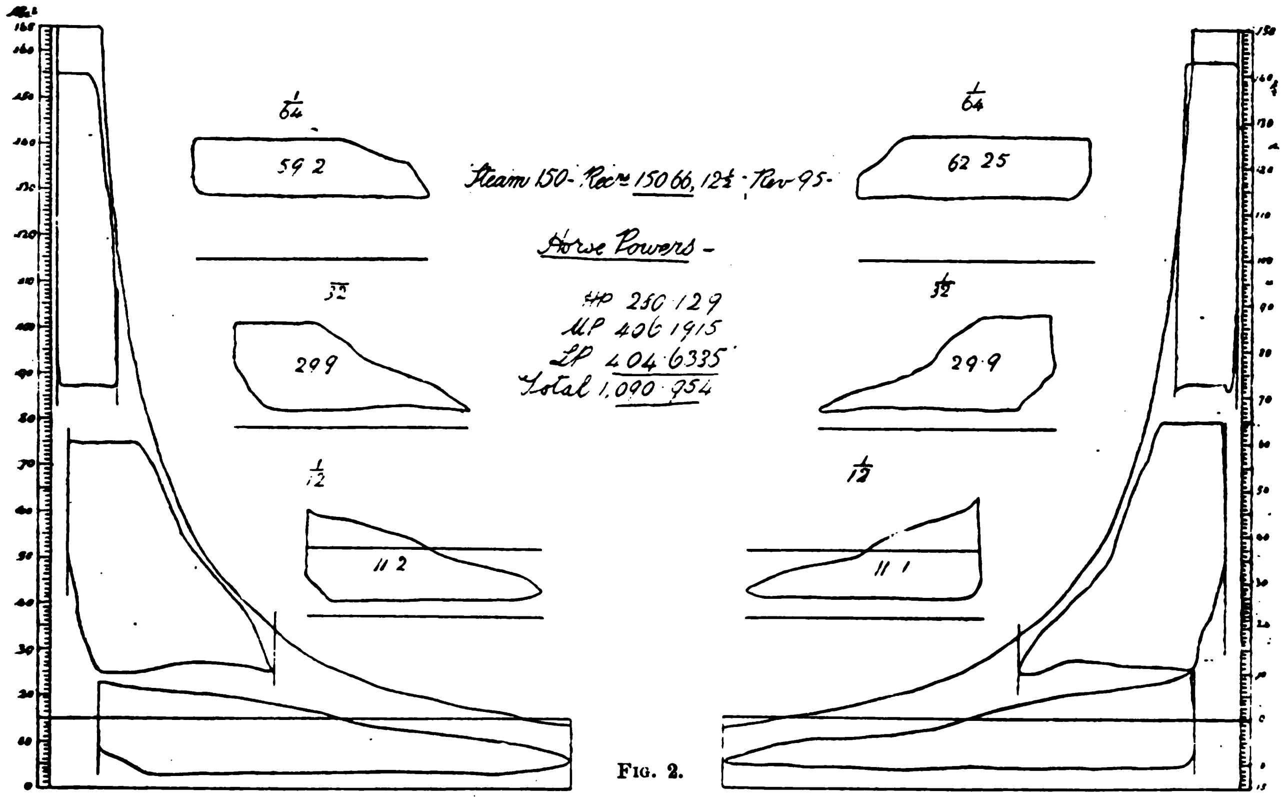

Fig. 2.

diagrams, and the good record both as regards coal and water.

We would draw particular attention to the high and mid-pressure steam lines and to the mid-pressure cut-off, both of which are evidence of good efficiency, the second being equivalent in cut-off to a Corliss valve.

It would be interesting to ascertain the reason of the drop in pressure between the high and mid-pressure cylinders; however, although this appears to be a fault, the fact remains that as a whole the result is very satisfactory.

As regards other matters, the diagrams speak for themselves, so we need not add any further description with reference thereto.

LAUNCHES AND TRIAL TRIPS.

LAUNCHES—English.

Hyades.—On May 24th Messrs. John Blumer & Co. launched at Sunderland a new steamer of the spar-decked type, specially designed to carry cattle, for Messrs. R. P. Houston & Co.'s River Plate Line. She takes the highest class at Lloyd's. Length over all, 365 ft.; breadth, 47 ft.; depth, moulded, 27 ft. 6 in. She has been built on the deep-frame system. The engines and boilers have been built by Messrs. John Dickinson & Sons, Limited, and are of the triple-expansion type, the cylinders being 26 in., 43½ in., and 72½ in. by 48in. stroke. The vessel was named *Hyades*, by Miss Hopkins, of Liverpool.

Holmgarth.—On May 24th there was launched at Southampton from the yard of Messrs. J. G. Fay & Co., Limited, the single screw steel tug *Holmgarth*, built to the order of Messrs. R. & J. H. Rea, and intended for service in Southampton waters. Her principal dimensions are:—Length, between perpendiculars, 73 ft.; breadth, moulded, 16 ft.; depth, moulded, 9 ft. She is propelled by a set of inverted direct-acting compound surface-condensing engines, with cylinders 15 in. and 30 in. diameter, and 22 in. stroke. Steam is supplied from a cylindrical return tube boiler of 10 ft. diameter by 10 ft. in length, and designed for a working pressure of 110 lbs.

Beta.—On May 25th the steel screw steamer *Beta*, built by Messrs. Wm. Gray & Co., Limited, for Mr. B. J. Van Hengal, Amsterdam, was launched at West Hartlepool. She is intended for the timber and general cargo trades, and takes Lloyd's highest class, her dimensions being: length, overall, 280 ft.; breadth, 39 ft.; depth, 18 ft. 2 in. She has a half poop, raised quarter-deck and part awning-deck, with houses on deck for cabins. The hull is built with deep framing, cellular double-bottom, and a large after-peak tank, and the equipment will be of the most improved description, including steam windlass, steam steering-gear, patent donkey boiler, four steam winches, etc. She will have triple-expansion engines made at the Central Marine Engine Works of Messrs. Wm. Gray & Co., Limited, with cylinders 19 in., 30½ in., and 51 in. diameter, and a piston stroke of 36 in., and two steel boilers to work at a pressure of 160 lbs. per square inch. The ceremony of naming the ship was gracefully performed by Miss Rachel Lotinga, daughter of Mr. A. Lotinga, ship broker and owner's agent at West Hartlepool.

Chieftain.—On May 25th a tug steamer, built to the order of the Glasgow and Greenock Shipping Co., was launched by Messrs. Eltringham & Co., South Shields. The vessel, which is intended for service on the Clyde, is of the following dimensions. Length, 110 ft.; breadth, 19 ft.; and depth, 10 ft. The ceremony of naming her the *Chieftain* was performed by Miss Bessie Blanche, daughter of Mr. Richard Blanche, Greenock, manager of owners.

Wilcannia.—On May 26th there was launched from the yard of the Sunderland Shipbuilding Co., Limited, a steel screw steamer, built to the order of Mr. W. Lund, of London, making the sixth vessel built by the firm for his Blue Anchor Line, and a sister steamer to the s.s. *Narrung* and *Wakool*, belonging to the same firm. The dimensions of the vessel are as follows:—Length between perpendiculars, 400 ft.; breadth, 48 ft.; depth moulded, 31¼ ft.; classed 100 A1 Lloyd's. The boat has been specially designed for the owner's line running between London and Australia; her carrying capacity is 6,000 tons. Accommodation is fitted for 50 first-class and 50 third-class passengers. The steamer is built with full poop and topgallant forecastle, with long citadel bridge, at the forward end of which is placed accommodation for captain and first-class passengers, together with lavatories, bathrooms, and rooms for stewardess, &c.; and at the after end of this bridge accommodation is fitted for the officers, engineers, apprentices, purser, refrigerating and electrical engineers, together with officers' and engineers' mess-rooms. On top of this bridge deck a large house is built, containing berths for several first-class passengers, doctor, and steward; also bar and pantries. At the fore end of this house, and forward of the machinery space, there is a large dining saloon for first-class passengers, which is panelled out in two shades of polished oak; handsome mirrors are fitted with carved-oak caps and moulding relieved with gold, the whole of the fittings being of solid white metal. There are three dining tables with revolving chairs, also sofas, bookcases, sideboards, &c., complete. This saloon is specially lighted and ventilated with dome skylight and large sidelights all round. On the top of the main saloon is a large music-room, fitted in light oak with a number of mirrors, and tastefully decorated. This room is also lighted by a large dome skylight. In close proximity to the saloon is a large smoking-room, panelled in Australian hardwood and mirrors, luxuriously fitted with lounges, tables, &c., complete. Covering all this accommodation is a complete shade deck extending to the sides of the vessel, forming a promenade for the first-class passengers 120 ft. by 48 ft., the only erection upon which is the captain's house and steering-house. The former is handsomely fitted up in oak and mahogany, with sleeping berth, slate-top chart table, racks, &c. Accommodation for 50 third-class passengers is placed in the topgallant forecastle and under the fore end of the bridge, whilst the crew are all berthed in the full poop aft. The galley is built round the main mast on the spar deck, so as to be conveniently placed for the stewards, cooks, and crew, and is of exceptionally large dimensions and well ventilated; the range, steam, and baker's ovens, &c., are of extra large size. The steam-steering gear is by Messrs. Davis & Co., and stands in the engine-room casing at the after end, and is connected to the wheel-house on the shade deck by rods and bevelled gear, the after steering gear is of extra size and power by Mr. John Lynn, of Pallion. There are eight steam winches for working the cargo, which have been built to the owner's special requirements, with extra large drums, &c., by Mr. Robert Welford, of Pallion. Powerful steel derricks, &c., are fitted, and all gear for handling light and heavy cargoes. Abreast the main mast there are two large sidehouses connected by overhead bridge to the galley, built with complete accommodation for quartermasters, carpenters, boatswains, and the various petty officers, including messroom for same, &c. The whole vessel is entirely lighted throughout by electricity by Messrs. Troup & Curtis, of London, the whole of the forehold and fore 'tween decks (which are of a very large capacity) have been insulated by Messrs. Gregson & Co., of London, for the carrying of frozen meat, the necessary refrigerating machinery (which stands immediately above this hold) is manufactured by the Haslam Foundry and Engineering Co., of Derby. This vessel will be placed on the Admiralty list: the 'tween decks (which are exceptionally high) are pierced all fore and aft for the accommodation of troops or emigrants. Special attention has been paid to the ventilation of passengers' accommodation throughout the vessel, The main engines are by the North-Eastern Marine Engineering Co., Limited, of Wallsend-on-Tyne, the cylinders being 28 in., 41 in., and 78 in. by 54 in. stroke, with bronze propeller. The boilers are four in number, single-ended, working at a pressure of 180 lbs., and are fitted with Howden's patent forced draught. During construction the hull has been built under the constant inspection of Captain Ilbery, under whose command she will sail, whilst the engines have been supervised by Mr. Shanks, of London. The vessel, when considered as a passenger and cargo steamer combined, is one of the largest and finest that has been built on the Wear. The launching ceremony was successfully performed by Mrs. Mackenzie, of Melrose, who named the vessel *Wilcannia*.

Floriston.—On May 26th Messrs. Ropner & Son launched from their shipbuilding yard a very fine steel screw-steamer 325 ft. long; her machinery will be supplied by Messrs. Blair & Co., Limited. She has been built to the order of a Newcastle firm, and as she left the ways received the name of *Floriston* from Miss Adams, daughter of Captain Adams, who will take command of the steamer on completion.

Luciline.—On May 26th Messrs. Sir W. G. Armstrong, Whitworth & Co., Limited, launched the above oil tank steamer, building to the order of Messrs. Lane & Macandrew, of London. The vessel, like her sister ship *Oriflamme*, has been constructed under the immediate supervision of Messrs. Flannery, Baggallay & Johnson, of London and Liverpool, and is of the following dimensions: 335 ft. by 45 ft. by 29½ ft. moulded depth. A very powerful installation of pumping arrangements has been supplied, and electric light is fitted throughout. The engines are being erected by the Wallsend Slipway and Engineering Co., Limited, and are of the following dimensions, namely, 24 in. by 40 in. by 66 in. diameter, with a stroke of 48 in., the two large single-ended boilers working at 160 lbs. pressure. Both hull and machinery are constructed to the highest class of Bureau Veritas, and in conformity with the Suez Canal regulations.

Naudu.—On May 27th there was launched at Selby, by Messrs. Cochrane & Cooper, Limited, a steam trawler for the Grimsby fishing trade, which has been built to the order of Messrs. Baskcombe & Taylor, of Grimsby. She was named *Naudu*. The *Naudu* is the sister ship to the *Merlin*, recently built for the same firm, and is to be engined by Messrs. C. D. Holmes & Co., of Hull.

Elsie.—On May 27th there was launched at Selby by the Selby Shipbuilding and Engineering Co., Limited, a steam trawler, built to the order of the Central Steam Fishing Co., which was named *Elsie*. She is a sister ship to the *Kathleen*, recently built for the same owners.

Formby.—On May 29th there was launched from the yard of Messrs. R. Williamson & Son, Workington, a finely modelled screw-steamer, built to the highest class at Lloyd's, for Messrs. J. Edwards & Co., Liverpool. Her dimensions are:—Length, between perpendiculars 152 ft. 3 in.; breadth, 23 ft. 6 in.; depth, moulded, 12 ft. 3 in., and designed to carry 520 tons on Lloyd's freeboard. The engines are to be supplied by Messrs. Ross & Duncan, of Govan, and are of the compound type, having two cylinders 19 in. and 38 in. with a stroke of 27 in.

Cassandra.—On May 29th a new steam yacht, built and designed by Messrs. Day, Summers & Co., to the order of Mr. F. M. Huth, was launched at Southampton. The principal dimensions are as follows:—Length between perpendiculars, 130 ft.; breadth, 19 ft.; depth, 12 ft. 6 in.; tonnage (builders' measurement) 228 tons. The engines are of the triple-expansion surface-condensing type, with cylinders 11 in., 17½ in., and 28 in. diameter, and 21 in. stroke; pressure, 160 lb. The yacht was named *Cassandra*.

Manchester Importer.—On May 29th there was launched from the yard of Messrs. Irvine's Shipbuilding and Dry Docks Co., Limited, a finely modelled steel screw cattle and cargo steamer named the *Manchester Importer*, built to the order of the Manchester Liners, Limited, of which Sir Christopher Furness is chairman. The vessel is being built expressly for the Manchester Liners service from the Manchester Canal to Canada, and has a cargo capacity of 10,666 tons. She is of the following dimensions, viz.:—Length, 382 ft. by 48 ft. beam, and 36 ft. 6 in. depth, and has two masts, and is rigged fore and aft with telescopic topmasts to suit the Manchester Canal bridges, and has been built under special survey to take the highest class in Lloyd's registry. She is built to the highest grade with one steel deck, and has an iron shelter deck specially strengthened, considerably in excess of Lloyd's requirements for the Atlantic trade, extending over the whole length, and above this is a bridge deck 110 ft. long. All the available space under the shelter deck, and along each side under the bridge deck, is fitted throughout to pass the American and Canadian regulations, with the most improved and modern arrangements for carrying about 500 head of cattle. The accommodation for saloon, captain, spare staterooms, &c., is arranged on the bridge-deck in a large steel deck-house, and separate houses for officers and engineers, and the seamen; firemen under shelter deck forward, and the cattlemen's quarters are under the shelter deck aft. A cellular double-bottom is fitted all fore and aft for water ballast, and also four separate tanks under engine, and boiler space for fresh water for supplying cattle. Water ballast is also arranged to be carried in a deep cargo tank and in the after peak, giving the vessel a total water ballast capacity of over 1,600 tons. The vessel is divided into six watertight compartments by means of seven steel bulkheads, all of which extend to the upper deck. Each compartment is fitted with complete iron and wood grain divisions. A most complete system of ventilation has been arranged to ensure the safe carriage of cattle, grain, or other cargoes. The vessel has six hatches, eight powerful steam winches, and ten derricks provided for the rapid loading and discharging of cargoes. A powerful steam windlass is fitted forward for working the cables, and a combined hand and steam-steering gear of special design is fitted in a large steel wheelhouse on the after end of the shelter deck. Special steering telegraphs are fitted for navigating purposes whilst going up the canal. The vessel is lighted throughout by electricity, and will be fitted as a first-class cattle and cargo steamer, including all the most modern improvements for the Atlantic trade. The engines are being constructed by Messrs. William Allan & Co., Limited, Sunderland. They are of the inverted triple-expansion type, having cylinders 25 in., 41 in., 69 in. by 48 in. stroke, steam being supplied by three single-ended boilers 14 ft. 3 in. diameter by 11 ft. long, with a working pressure of 180 lbs. All the shafting is very considerably in excess of Lloyd's requirements. The propeller is of manganese bronze, and the auxiliary machinery is of the most modern type. As the vessel left the ways the christening ceremony was gracefully performed by Mrs. Schiff, Lowndes Square, London, wife of one of the directors of the Manchester Liners, Limited. The hull of the vessel has been specially designed and built for the Manchester Canal trade under the supervision of Mr. A. H. Walker, the machinery by Mr. J. F. Kitching, shipbuilding and engineering superintendents for Sir Christopher Furness, and also Mr. James Robinson, marine superintendent for the Manchester Liners, Limited. A duplicate of the *Manchester Importer*, now in an advanced stage of construction, is expected to be launched by the builders in July, and is to be named the *Manchester Shipper*. There was a large company present to witness the launch, including Sir Christopher and Lady Furness, Mr. and Mrs. Schiff, Major D. G. and Mrs. Irvine, Sir Edward Gourley, M.P., Mr. and Mrs. Candlish (Shotton Hall), Mr. and Mrs. Withy, &c.

Hugin.—On June 3rd there was successfully launched from the shipbuilding yard of Messrs. Wood, Skinner & Co., Limited, Bill Quay, Newcastle-on-Tyne, a handsome steel screw-steamer which has been built to the order of Messrs. Bruusgaard, Kjosterud & Co., of Drammen, Norway. The vessel is of the improved single-deck type with bridge and topgallant forecastle, and is of the following dimensions, viz.:—Length, 248 ft.; breadth, 35 ft.; depth, moulded, 20 ft. 6 in. She will be rigged as a fore-and-aft schooner and fitted with telescopic topmasts. The vessel is built to the highest class, viz.—1 A1* Norwegian Veritas, and has been surveyed during construction by Mr. Lauritz M. Bodin, of Sunderland, the local representative; and also superintended by Mr. Norman Burnett, of Newcastle-on-Tyne, on behalf of the owners. The vessel will be fitted with all the latest improvements and appliances for facilitating the rapid loading and discharging of cargo, general working and navigating: including combined steam and hand-steering apparatus amidships, screw gear aft, direct steam windlass, powerful steam winches, &c. The saloon, captain's berth, spare state rooms, &c., are in a large house on bridge deck amidships, with chart room and flying bridge above; the officers' accommodation being in house aft on main deck, whilst the crew are berthed in the topgallant forecastle; water ballast is provided in the cellular double bottom, all fore and aft. Her engines have been constructed and will be fitted by the North-Eastern Marine Engineering Co., Limited, at the Northumberland Engine Works, Wallsend-on-Tyne. These are of the improved triple-expansion type, having cylinders 18½ in., 30 in., and 49 in. diameter, respectively, with a stroke of 33 in.; steam being supplied by a large steel multitubular boiler, working at 160 lbs. pressure per square inch. As the vessel left the ways she was christened *Hugin* by Miss Minnie Skinner, of South Shields. When completed the steamer will be commanded by Captain Fornebo, of Christiania, Norway. This is the fourth vessel recently constructed by the builders for Messrs. Bruusgaard, Kjosterud & Co., whilst they have a fifth steamer in course of construction on the stocks for the same owners.

Enidwen,—On June 6th there was launched by Messrs. John Readhead & Sons, at West Docks, South Shields, a new screw-steamer, built to the order of Messrs. W. H. & C. T. Jones, Cardiff. The vessel, which is 353 ft. long, 46 ft. 6 in. broad, and 27 ft. 4 in. in depth, is of the improved single-deck type and classed A1 at Lloyd's under special survey. The steamer will be fitted with triple-expansion engines, also constructed by Messrs. John Readhead & Sons, having cylinders 24 in., 40 in., and 65 ins., by 45-in. stroke, steam being supplied by two large steel boilers working at a pressure of 160 lbs. per square inch. The vessel was named the *Enidwen* by Miss Jones, daughter of Mr. William Jones, of Cardiff, senior of the firm.

Portugal.—On June 7th Sir Raylton Dixon & Co., Limited, launched from Cleveland Dockyards, Middlesbrough, a fine steel screw mail and passenger steamer built to the order of Senhores Empreza Nacional de Navegacao a Vapor, of Lisbon. She is built to Lloyd's highest class, spar-deck rule, her principal dimensions being: 377 ft. by 45 ft. 6 in. by 29 ft. 9 in., and has a deadweight carrying capacity of over 5,000 tons. The upper decks are of steel, sheathed with teak. Accommodation for 80 first-class passengers will be provided for amidships with large dining saloon, &c., in house aft. The 250 second-class passengers will be accommodated on main deck. The whole of the accommodation has been designed and ventilated to meet the passenger requirements in a tropical climate. Triple-expansion engines will be supplied by Messrs. Thos. Richardson & Sons, Limited, of Hartlepool, having cylinders 28 in., 46 in., 77 in., by 48 in. stroke, provided with steam by two large double-ended boilers, working at 180 lbs. pressure. The vessel has been built under the supervision of Mr. T. C. Laws, of Liverpool. On leaving the ways she was gracefully named *Portugal* by Mrs. T. C. Laws.

Garonne.—On June 8th there was launched from the shipbuilding yard of Messrs. Robert Stephenson & Co., Limited, Hebburn, a finely-modelled screw steamer, the first of two to the order of the United Steamship Co., of Copenhagen. The ship, which is of the raised quarter-deck type, is of the following dimensions:—Length, between perpendiculars, 250 ft.; breadth, moulded, 35 ft.; depth, moulded, to main deck, 18 ft. 4 in., and depth, moulded, to quarter-deck, 22 ft. 4 in. The ship, which is built to the highest class in Bureau Veritas, is to be fitted out for the French wine trade. She has a cellular double bottom all fore and aft for water ballast, and has upper and lower decks of steel. The bow has been specially strengthened for ice to obtain Veritas P.R. class. She has a vertical donkey boiler, four powerful steam winches, a steam windlass, and steam and hand-steering gear. The crew are berthed forward under the topgallant forecastle, and the saloon and staterooms and the officers' and engineers rooms are in an upper bridge above the main bridge. All the rooms throughout are heated by steam. The engines, which are of the triple-expansion type, supplied with steam by two large single-ended boilers, are also supplied by the builders. The ship has been constructed under the supervision of Captain Rabe, and the engines under that of Mr. Fricke, the representatives of the owners. As the ship left the ways she was gracefully named *Garonne* by Miss Walker, daughter of the general manager of Messrs. Robert Stephenson & Co., Limited.

Manchester Corporation.—On Thursday, June 8th, Messrs. Furness, Withy & Co., Limited, launched from their Middleton Shipyard, West Hartlepool, the finely-modelled steel screw cattle and cargo steamer named the *Manchester Corporation*, built to the order of the Manchester Liners, Limited, of which Sir Christopher Furness is chairman. The vessel is built expressly for the Manchester Liners service from the Manchester Canal to Canada. Her dimensions are:—Length, 445 ft.; beam, 48 ft.; depth, moulded, 34 ft. The vessel has four masts, and is rigged fore and aft, with telescopic topmasts and funnel to suit the Manchester Canal bridges, and the scantlings of the vessel are considerably in excess of Lloyd's highest class. The *Manchester Corporation* is of the three-deck type, with two steel decks laid all fore-and-aft, and has poop, bridge, and forecastle, with strengthened wood shelter-deck between erections, and the vessel is strengthened considerably above Lloyd's requirements to suit the Atlantic trade. All the available space under the shelter-deck, upper deck, and bridge is fitted throughout to pass American and Canadian regulations, with the most improved and modern arrangements for carrying 756 head of cattle. The accommodation for the captain in the saloon and spare staterooms, &c., is arranged on the bridge deck in a large steel deckhouse, with separate house for officers. The engineers are housed at the fore end of bridge, the seamen and firemen under the forecastle, and the cattlemen in the poop. A cellular double-bottom is fitted all fore and aft for water ballast, and there are also four separate tanks under engine and boiler space for fresh water for cattle supply. A specially strengthened deep tank is fitted just aft of the engine room, and both fore and after peaks are fitted for water ballast, giving a total ballast capacity of 1,700 tons. The vessel is divided into nine watertight compartments by means of eight steel bulkheads. Each compartment is fitted with complete grain divisions. A most complete system of ventilation has been arranged to ensure the safe carriage of cattle, grain, or other cargoes. The vessel has eight hatches, eight powerful steam winches and 16 derricks provided for the rapid loading and discharging of cargoes. Special attention has been devoted to the bunkering arrangements of the vessel so that the bunkering can be carried out in an efficient manner. A powerful steam windlass is fitted forward for working the cables, and combined hand and steam-steering gear of a special design is fitted in the after end of the poop. The vessel is lighted throughout by electricity, and will be fitted as a first-class cattle and cargo steamer, including all the most modern improvements for the *Atlantic trade. The* engines will be supplied by Messrs. Sir C. Furness, Westgarth & Co., Limited, Middlesbrough; they are of the inverted triple-expansion type, having cylinders 28 in., 46 in., 78 in. by 54 in. stroke, steam being supplied by three single-ended boilers 14 ft. 9 in. by 12ft. diameter, with a working pressure of 190 lbs, Howden's forced draught being also fitted in connection with the boilers. The ceremony of christening the vessel *Manchester Corporation* was gracefully performed by the Lady Mayoress of Manchester.

Ormley.—On June 8th Messrs. Craig, Taylor & Co. launched from their Thornaby Shipbuilding Yard, Thornaby-on-Tees, a large steel screw-steamer, the particulars of which are as follow:—372 ft. by 48 ft. by 30 ft. 11 in. depth, moulded. She is built to the highest class in Lloyd's, spar-deck rule, with poop, bridge, and topgallant-forecastle; water ballast in cellular double-bottom fore and aft, also in peaks. She will be equipped with seven large double-powered steam winches, patent direct steam windlass, patent steam-steering gear, portable 10-ton derricks, screw gear aft, complete set of shifting boards for grain carrying, and all the latest improvements. She is rigged as a fore-and-aft schooner, to the Manchester Canal requirements. The accommodation for captain, officers, and engineers is in the central deckhouse on bridge, the crew being berthed in the forecastle. The main engines have been constructed by Messrs. William Allan & Co., Limited, Sunderland, the cylinders being 23½ in., 38½ in., 68 in. by 48 in. stroke, three large boilers working at 200 lbs. pressure. This vessel has been built to the order of the North of Ireland Steamship Co., Limited, Belfast (Mr. W. R. Rea, managing director), and under the superintendence of Mr. Joseph Lewis. As she left the ways she was gracefully christened the *Ormley*, by Miss Head, representing her mother, the Mayoress of Thornaby. This is the fourth vessel built by Messrs. Craig, Taylor & Co. for the owners.

Banderas.—On June 9th Messrs. William Pickersgill & Sons launched at Southwick, Sunderland, a steel screw cargo steamer of the single-decked type, built to the order of the Compania Naviera Vascongada, of Bilbao, of which Mr. Felix de Abasolo is managing director. The dimensions of this vessel are as follows:—Length, 295 ft.; breadth, 43 ft.; depth, moulded, 21 ft. She has been built to Lloyd's highest class under special survey, and has been designed to carry about 3,600 tons deadweight. The machinery and boilers are to be supplied by Messrs. Geo. Clark, Limited, of Southwick, the engines being of the triple-expansion type, having cylinders 21 in, 35 in., and 57½ in., with 39-in. stroke, and two large steel boilers with a working pressure of 160 lb. She was named *Banderas* by Miss Young, daughter of Mr. Young, of the firm of Messrs. Cairns, Young & Noble, of Newcastle-on-Tyne.

Wamba.—On June 10th Messrs. Cochrane & Cooper, Limited, launched from their Grovehill Shipyard, Beverley, a new steam trawler of the following dimensions—112 ft. by 21 ft. by 11 ft. 6 in. depth of hold, built to the order of the United Steam Fishing Co., Limited, Grimsby. Triple-expansion engines will be fitted by Messrs. C. D. Holmes & Co., and the vessel will be complete with all the most modern appliances for trawling. Miss J. Chesman named the vessel the *Wamba*, and after the ceremony the company adjourned to the offices of the builders to luncheon.

Floriken.—On June 21st Mr. Joseph Scarr launched from his yard at Grovehill, Beverley, a steel tug boat of the following dimensions:—Length overall, 69 ft.; beam, moulded, 16 ft. 5 in.; depth amidships, 9 ft. 3 in. She was built to the order of Mr. J. Constant, of London, and is the fourth Mr. Scarr has built for him. On leaving the ways she was christened *Floriken* by Mr. Marshall.

Swindon.—On Thursday afternoon, June 22nd, Messrs. Richardson, Duck & Co. launched from their yard a steel screw-steamer of the following dimensions:—Length overall, 351 ft. 9 in.; breadth extreme, 48 ft.; depth, moulded, 28 ft. 4 in.; tonnage, gross, about 3,860 tons. This vessel, which has been built to the order of Messrs. Evan Thomas, Radcliffe & Co., Cardiff, will class 100 A1 on Lloyd's register, and has been built under special survey. She is of the three-deck type with one deck laid, having poop bridge extending from mainmast to fore mast and topgallant-forecastle. Accommodation for captain and officers is provided in poop, engineers being berthed in iron sidehouses on bridge deck, and crew in topgallant-forecastle, which has been specially fitted with patent galvanised iron berths and a bathroom. A cellular double-bottom all fore and aft and fore-and-aft peak tanks are fitted for water ballast and equipment includes six steam winches, an auxiliary main boiler by Blair & Co. of 160 lbs. working pressure, steam windlass, stockless anchors, steam-steering gear, and all latest appliances for the economical and safe working of the vessel. The engines, by Messrs. Blair & Co., have cylinders 24 in., 40 in., and 66 in. by 45 in. stroke, steam being supplied by two single-ended boilers of 160 lbs. pressure. As the vessel left the ways she was named *Swindon* by Miss Maud Kitching, daughter of Mr. A. E. Kitching, Great Ayton.

Rowena.—On June 23rd Messrs. Wm. Gray & Co., Limited, launched the large steel screw-steamer *Rowena*, which they have built to the order of Messrs. Herskind & Co., of West Hartlepool. She is the 26th vessel which the builders have supplied to the order of Messrs. Herskind & Co. Her principal dimensions are :—Length, over all, 336 ft.; breadth, 47 ft.; and depth, 24 ft. 10 in., and she is built to Lloyd's highest class with poop, bridge, and forecastle, and fore-and-aft schooner rig. Very tasteful cabin accommodation is provided under the poop. The engineer's rooms are in houses on the bridge, and the crews' berths forward. The hull is built with deep frames and a cellular double bottom and after peak tank for water ballast. Steam windlass, steam-steering gear amidships, screw gear aft, steam winches, patent donkey boiler, and the whole of the outfit are of the most improved description. The engines are by the Central Marine Engine Works of Messrs. W. Gray & Co., Limited, on the triple-expansion system, with cylinders 24 in., 38 in., and 64 in. diameter, and 42 in. stroke, and two large single-ended boilers to work at 160 lbs. pressure per square inch. The ship has been built under the superintendence of Captain Petersen, and the machinery under that of Mr. J. R. Fothergill, on behalf of the owners. The ceremony of naming the *Rowena* was gracefully performed by Mrs. Herskind, of West Hartlepool, the wife of one of the owners.

Elswick Park.—On June 24th Messrs. W. Gray & Co., Limited, launched a large steel screw-steamer for the Elswick Steamship Co., Limited, Newcastle-on-Tyne, Messrs. Werdner-Hopkins & Co., managers. She will take the highest class in Lloyd's, and is of the following dimensions, viz.—Length, over all, 341 ft.; breadth, 47 ft.; depth, 27 ft. 4 in., with long bridge, poop, and top-gallant forecastle. The saloon, state-rooms, captain and officers' rooms, &c., will be fitted up in the poop, the engineers' accommodation in houses on the bridge-deck, and the crews berth in the forecastle. The hull is built with deep frames, cellular double bottom, and aft peak ballast tank, six steam winches, steam steering gear amidships, and hand screw gear aft, patent direct steam windlass, two patent donkey boilers, shifting boards throughout, stockless anchors, telescopic masts, with fore-and-aft rig boats on beams overhead, and all requirements for a first-class cargo steamer. Triple-expansion engines are being supplied by the Central Marine Engine Works of Messrs. Wm. Gray & Co., Limited, having cylinders 25 in., 40 in., and 65 in. diameter, with a piston stroke of 42 in., and large steel boilers for a working pressure of 160 lbs. per square inch. The ship and machinery are being completed under the superintendence of Mr. Walter Sage, of Hull, on behalf of the owners. The ceremony of naming the vessel *Elswick Park* was gracefully performed by Miss Marjorie Hopkins, daughter of the managing owner.

Surrey.—Lately the *Surrey*, a large four-masted steel screw steamer, constructed by Messrs. R. & W. Hawthorn, Leslie & Co., Limited, to the order of Messrs. Wm. Milburn & Co., London, has been launched at Hebburn-on-Tyne. Her principal dimensions are:—Length, over all, 435 ft.; breadth, 54 ft.; depth, 40 ft. to shelter deck. The vessel has been built in excess of the highest class at Lloyd's, and is intended for carrying frozen meat from the Colonies. The engines have been built by Messrs. R. and W. Hawthorn, Leslie & Co., Limited, and are of the triple-expansion surface-condensing type, with cylinders 30 in., 48 in., and 78 in. diameter, and 54 in stroke. The vessel was christened *Surrey*.

LAUNCHES.—Scotch.

Seagull.—On May 8th there was launched at Rutherglen, for the Manchester and Liverpool Transport Co., Limited, Manchester, a steel schooner-rigged steamer, of about 200 tons gross, named the *Seagull*.

Craigellachie.—On May 23rd there was launched by Messrs. A. Rodger & Co., at Port-Glasgow, a steel-screw steamer of 3,300 tons gross, to carry 5,500 tons deadweight, for Messrs. Russell, Huskie & Co., Leith. Her dimensions are :—Length, 326 ft.; breadth, 48 ft.; depth, 26 ft., 4½ in. The ceremony of naming the vessel *Craigellachie* was performed by Mrs. Russell, wife of one of the owners. Messrs. Hall, Brown, Buttery & Co., Glasgow, will supply the machinery.

Noyra.—On May 24th Messrs. Paul Jones & Son launched at Gourock the racing cutter *Noyra* for Mr. M. Greenlees, jun., Paisley. The *Noyra* belongs to the new 20-ton one-design Clyde class, designed by Mr. Alfred Mylne, Glasgow, of which five have been built for this season. Her principal dimensions are :—Length over all, 50 ft.; on water line, 35 ft.; beam, 11 ft.; and drawing 8 ft.

Teodoro de Larrinaga.—On Wednesday, May 24th, Messrs. Russell & Co., Kingston Shipbuilding Yard, Port-Glasgow, launched a steel screw-steamer named *Teodoro de Larrinaga*. Length 345 ft., by beam 49 ft. 9 in., by depth 28 ft. 6 in., and carrying about 6,400 tons deadweight on Lloyd's summer freeboard. This vessel was purchased by Messrs. Larrinaga & Co., of Liverpool. After launch she was towed to the Victoria Harbour, Greenock, where she will have her engines put on board, and be completed ready for sea. Her engines, which are built by Messrs. Rankin & Blackmore, of Greenock, are 25 in., 41 in., 67 in., by 45 in. stroke, and are fitted with Howden's forced draught. The steamer is of the spar-decked type, and is fitted with the most modern improvements for rapid handling and discharge of cargo, the accommodation for all officers being on the top of the bridge. She was completed under the superintendence of Captain L. de Ojinaga.

Vienna.—On May 25th there was launched from the shipbuilding yard of Messrs. Barclay, Curle & Co., Limited, Whiteinch, the first of two steamers which are being built for Messrs. Gow, Harrison & Co., Glasgow. The vessels are designed for general trade, having eight steam winches, long double derricks, &c., for the rapid handling of cargo. They are classed in the British Corporation's highest class. The principal dimensions are 376 ft. by 48 ft. by 29 ft., moulded; she measures about 4,100 tons gross, her deadweight carrying capacity is 6,700 tons. The saloon, captain's room, and staterooms are arranged in a large deck house on the bridge deck. The officers' and engineers' rooms are placed alongside the machinery casings on bridge deck. The crew and cattlemen are berthed forward. The machinery, which is being supplied by the builders, is on the triple-expansion principle, the cylinders are 25 in., 41 in., 67 in., by 48 in. stroke, steam being supplied by two large boilers at a working pressure of 180 lbs. and fitted with Howden & Co.'s forced draught. The superintendence was conducted under Mr. George Macfarlane, of Glasgow. As the vessel left the ways she was gracefully named the *Vienna* by Mrs. Bilsland, 28, Park Circus, Glasgow. thereafterwards proceeding to the harbour to take in her machinery.

Domingo de Larrinaga.—On May 26th Messrs. Robert Duncan & Co., Limited, launched at Port-Glasgow the steel screw-steamer *Domingo de Larrinaga*, built to the order of Raeburn & Verel, Glasgow, and transferred by them to F. D. Larrinaga & Co., Liverpool. Dimensions ; 376 ft. by 48 ft. by 29 ft., moulded; about 6,600 tons deadweight. Triple-expansion engines by Hall-Brown, Buttery & Co., Govan, Glasgow. Cylinders, 27 in., 43 in., 72 in., by 48 in. Two boilers with Howden's forced draught.

Ytoroi.—On May 26th Messrs. William Simons & Co., Limited, launched complete from their works at Renfrew the second of two powerful dredging vessels which they have constructed to undertake extensive dredging operations in connection with the improvement of Port Arthur and Talienwan. The vessel has been built under the direction of Mr. Totshyski, inspecting engineer, assisted by Mr. Johnson. The dredger, in addition to being provided with a chain of buckets for discharging into barges alongside, is fitted with a sand suction pump, also a mud discharging pump, to which is attached fully 2,000 ft. of shore discharging pipes, carried on floating pontoons having flexible joints. The vessel is capable of dredging and discharging 1,000 tons of spoil per hour, and of working to a depth of 40 ft. below the water level. Two pair of compound surface-condensing engines are fitted for propelling the vessel at a speed of seven knots per hour. It is constructed in accordance with the rules of Bureau Veritas for the highest class for a vessel of this type. Electric light installation is provided for working day and night. A repairing-room is also fitted on board, with turning lathe, drilling and planing machine, &c. As the vessel left the ways she was named *Vtoroi* by Mrs. Totshyski.

Gleniffer.—On May 27th Messrs. David & William Henderson & Co. launched at Partick, on the Clyde, a large schooner yacht, which they have built for Mr. James Coats, Ferguslie House, Paisley, from designs and under the special supervision of Mr. G. L. Watson. The yacht is built of steel, to class 100 A1 in Lloyd's Yacht Register; has a length over all of 185 ft., with a yacht measurement tonnage of about 500 tons, and was named *Gleniffer*.

Mingary.—On May 27th the Ailsa Shipbuilding Co. launched at Troon a steel screw steam yacht, designed by Mr. G. L. Watson for Mr. C. D. Rudd, of Shielbridge, by Fort William. Her dimensions are:—Length over all, 211 ft.; length on load water line, 175 ft.; breadth, moulded, 27 ft. 3 in.; depth, moulded, 15 ft. 6 in.; tonnage, about 650 tons, yacht measurement. The engines, which are by Messrs. Dunsmuir & Jackson, are of the triple-expansion type. The yacht was named *Mingary*.

Sirdar.—On May 27th the Grangemouth Dockyard Co. launched from their yard at Grangemouth the steel screw-steamer *Sirdar*, built to the order of Messrs. Orders & Handford, of Newport, for the Orders & Handford Steamship Co., Limited. This vessel is the second built for Messrs. Orders & Handford by the Grangemouth Dockyard Co. She is of exceptionally strong construction, on the bulb angle frame and stringer principle, providing holds clear of obstruction, with large hatches for self-trimming. The *Sirdar* is of the single-deck type, with bridge and forecastle, and is fitted with the most modern appliances for rapid and economical working. The dimensions of the vessel are: 240 ft. by 36 ft. 6 in. by 15 ft. 5 in., and the deadweight carried is 2,200 tons on Lloyd's summer freeboard. Triple-expansion engines, having cylinders of 19 in., 30½ in., and 50 in. by 36 in. stroke, with a large steel boiler working at 160 lbs. pressure, will be supplied by Messrs. Dunsmuir & Jackson, of Govan. The construction of the vessel has been superintended by Mr. Boddy, consulting and superintendent engineer, of Newport. As the vessel took the water the naming ceremony was gracefully performed by Miss Clotilde James, daughter of Mr. Christopher James, of Swansea.

Tayside.—On May 27th Messrs. Gourlay Brothers & Co.' Camperdown Shipyard, Dundee, launched the steam trawler *Tayside*, built for the Tay Trawling Co., Limited. Principal dimensions 105 ft., by 20 ft., by 11 ft. moulded. Gross tonnage 137, class 100 A1 at Lloyd's. Schooner-rigged and of the usual flush-deck type. Holds fitted up with fish pounds and boards. and a large cross bunker and feed-water tank for boilers. Trawling gear on the "Otter" system. Machinery, supplied by the builders, consists of a set of triple-expansion engines, and a large single-ended boiler, which is designed to give a speed of between 11 and 12 knots on trial.

Algarve.—On May 29th there was launched by Messrs. Lobnitz & Co., Limited, at Renfrew, a screw-steamer of 1,274 tons, for the United Steamship Co., Copenhagen. The vessel is fitted by the builders with triple-expansion engines of 1,400 H.P. On leaving the ways the vessel was named *Algarve* by Miss M'Call.

Waverley.—On May 29th Messrs. A. & J. Inglis, Glasgow, launched a new passenger steamer for the North British Steampacket Co., named the *Waverley*. This vessel is of larger dimensions than any other of the company's fleet, and is intended for the daily excursion around Bute which proved so popular last season, and for the evening run to Kirn, Dunoon, and Rothesay. The *Waverley* has a spacious dining cabin under the main deck aft, a comfortable tea-room at entrance to deck saloon, and has accommodation for a large number of tourists. She will shortly be placed on the station in connection with fast trains to Craigendoran.

Claughton.—On May 30th there was launched from the shipbuilding yard of Messrs. John Scott & Co., at Kinghorn, a steel twin-screw passenger ferry steamer for the County Borough of Birkenhead Corporation Ferries. The vessel's dimensions are as follows:—Length, 150 ft.; breadth on water line, 38 ft.; breadth on main deck, 41 ft.; depth, moulded, 11 ft. 9 in. She is handsomely fitted up, and in conjunction with her sister ship the *Lancashire* launched by the same builders on February 8th, is far ahead of anything presently running on the Mersey river. The promenade deck is about 133 ft long, and is fitted with sparred seats all round, made buoyant by airtight cylinders, so that in the event of the vessel foundering the seats would float off, and so act as life rafts. The captain's and steersman's platforms are on this deck, and each are fitted up with the latest improvements in steering gear, telegraphs, &c. She has a complete installation of electric light. The engines are of the twin quadruple-expansion type of the Yarrow-Tweedie patent, and are a fine set, capable of driving the vessel at 12½ knots, and reflect great credit on Mr. Weir, the engineering manager of Messrs. John Scott & Co. The launch took place at 6.15 p.m., and as the vessel began to glide down the ways she was gracefully named the *Claughton* by Miss Crawford, of Abden Villa, Kinghorn. The vessel was launched with steam up, and immediately steamed off to Burntisland Dock.

Kelvingrove.—On May 30th Messrs. Archibald McMillan & Son, Limited, Dumbarton, launched the steel-screw steamer *Kelvingrove*, of 5,000 tons carrying capacity, built to the order of the Glasgow Steamship Co. The dimensions are 345 ft. by 45 ft. by 26 ft. 9 in. to main deck, above which there is also fitted a complete shelter deck. The decks are being fitted for cattle, and the system adopted for water service and ventilation is of the most perfect description. She is being fitted with triple expansion machinery for a 10¼ knot sea service, and is amply provided with the most modern appliances for the rapid handling of cargo. Her accommodation for captain, officers, and engineers is all on top of shelter deck amidships, the crew being berthed in the poop, and the cattlemen forward. The naming ceremony was gracefully performed by Mrs. John Albert Black, Duneira, Row. The vessel and machinery have been built to Lloyd's highest class, and under the superintendence of Lloyd's surveyors and Mr. George McFarlane, of Glasgow.

Triton and **Oberon.**—On May 31st Messrs. Scott & Sons launched at Bowling on the Clyde two screw lighters of dimensions 66 ft. 6 in. by 18 ft. 3 in. by 9 ft. 6 in., moulded, built to the order of Messrs. Richard Munro & Co., Glasgow. Compound tandem engines are to be fitted on board by Messrs. Walker, Henderson & Co., Bishop Street, Glasgow. On moving down the ways the steamers were named *Triton* and *Oberon* respectively by Miss Munro.

Eemstroom.—On May 31st Messrs Carmichael, Maclean & Co., Greenock, launched from their shipbuilding yard, the steel screw-steamer *Eemstroom*, to the order of a firm in Holland. The dimensions are:—Length, 235 ft. 3¾ in.; breadth, 33 ft.; depth, moulded, 17 ft.; with a deadweight capacity of about 1,000 tons, and a gross tonnage of 1,300 tons. The vessel has been built to Bureau Veritas highest class, is of the well-deck type, and is fitted with cellular double bottom all fore and aft, with the exception of the space under the boilers, and is furnished with all modern appliances for the quick working of ship and cargo, which include three steam winches, steam windlass, and steam steering-gear, and is also fitted with electric light. Under the bridge deck there is accommodation for passengers, captain, and officers, and under the forecastle deck for crew. The engines will be supplied by Messrs. Muir & Houston, Limited, Glasgow—triple-expansion; 20 in., 23 in., and 55 in., by 36 in. stroke; and two large boilers, &c. The christening ceremony was performed by Miss Doris Carmichael, Ardenlee, Greenock.

Neptuno.—On June 1st there was launched from the yard of Messrs. Murdoch & Murray, Port-Glasgow, a finely modelled steel twin-screw steamer, named *Neptuno*, designed for passenger and cargo service on the River Amazon. The vessel is very complete in every respect, all the woodwork being of selected teak. Accommodation has been provided in staterooms for 44 first-class passengers. A complete installation of electric light has been fitted up, including search light, and several large electric fans are placed in convenient positions. The principal dimensions are:—Length, 160 ft.; breadth, 32 ft.; depth to promenade deck, 17 ft. 4 in. After the launch the vessel was towed to Glasgow, where Messrs. Hall-Brown, Buttery & Co. will fit two sets of compound engines of large power.

Auchenarden.—On Thursday, June 1st, Messrs. Russell & Co., Kingston Shipbuilding Yard, Port-Glasgow, launched a steel spar-deck screw-steamer named *Auchenarden* to the order of the Auchen Steamship Co., Limited, Glasgow, of which Mr. T. Paterson Purdie is manager. Her dimensions are 340 ft. by 46 ft. by 28 ft. 6 in., with a deadweight carrying capacity of about 5,800 tons on Board of Trade summer freeboard. She is built to the highest class at Lloyd's, and has all accommodation for officers and engineers on top of bridge; has poop, bridge, and topgallant forecastle; and provision is made to enable the vessel to carry grain in bulk. After lunch the vessel was towed to the Victoria Harbour, Greenock, where her machinery will be put on board by Messrs. Rankin & Blackmore. Her engines are 23 in., 39 in., 65 in., by 45 in. stroke. She has been constructed under the superintendence of Mr. Peter Jackson, consulting engineer, Glasgow, assisted by Captain Peat, who is to command the vessel.

Nickolaeiff.—On June 6th Messrs. Fleming & Ferguson, Limited, Paisley, launched from their yard the powerful self-propelling bucket-ladder dredger *Nickolaeiff*, built to the order of the Imperial Russian Government. She is to be employed in carying out improvements on the ports of the Sea of Azov. She is built to cut her own flotation, and will be equipped with all the most modern appliances.

Amadavat.—On June 7th Messrs. Taylor & Mitchell launched at Greenock a steam trawler 108 ft in length, 21 ft. in breadth, and 12 ft in depth, moulded, for Messrs. J. Chant & Paddon, Plymouth. The vessel was named *Amadavat*, and will be supplied with triple-expansion engines by Messrs. Tindall & Co., Hull

Knowsie.—On June 8th a steam trawler, named the *Knowsie*, was launched by Messrs. John Duthie & Co., Montrose, for the Frazerburgh and North of Scotland Trawling Co., Limited,

Commander.—On June 8th Messrs. Hawthorns & Co., Limited, launched at Leith the first of two steam trawlers which they are at present building for Mr. Thomas Devlin, jun. She will be fitted with triple-expansion engines, and was christened *Commander*.

Golden Eagle.—On June 9th Messrs. Ramage & Ferguson, Limited, launched a full-powered steam yacht, built to the order of Sir Samuel E. Scott, Bart., Sundridge Park, Bromley, Kent, from the design of Messrs. G. L. Watson & Co., of Glasgow. The principal dimensions are:—Length, 150 ft. on water line; breadth, 24 ft. 10 in.; and depth, moulded, 15 ft. 6 in. The machinery, constructed by the same firm, consisting of a set of triple-expansion engines, having cylinders 14 in., 22 in., 36 in. diameter by 24 in. stroke, steam being supplied from a large multitubular boiler, working at a high pressure. The yacht's deckhouses and cabins are to be fitted up in a most luxurious manner, and when finished she will be a decided acquisition to the yachting fleet, having all the most modern improvements fitted. On leaving the ways the vessel was named *Golden Eagle* by Lady Farquhar, mother of the owner. The builders entertained a company after the launch, when the toasts usual on such occasions were duly honoured. Lady Farquhar replied personally to the toast of her health.

Duke of Rothesay.—On June 9th there was launched from the Caledon Shipbuilding and Engineering Co.'s yard, Dundee, a new steamer for the Dublin and Glasgow Steam Packet Co. (the Duke Line). The vessel has been specially designed for the cross-Channel service and for the conveyance of passengers, cattle, and general cargo. Her dimensions are:—Length, 276 ft.; breadth, 35 ft.; depth, 23 ft. 9 in.; gross tonnage, 1,250. The engines are of the triple-expansion type, and there are two large double-ended boilers with a working pressure of 180 lb. per square inch. The vessel was christened *Duke of Rothesay* by Miss Macnie, daughter of the chairman of the owning company.

Undine.—On June 14th Messrs. Mackie & Thomson launched at Govan the steam trawler *Undine*, which they have built for the South African Fisheries Co., Limited. The firm is new, having been formed recently for the purpose of developing the steam fishing industry off Cape Colony, and the *Undine* is their first vessel. The *Undine* is a steam trawler of 185 tons gross, 105 ft. in length, 21 ft. in breadth, and 11 ft. 7 in. in moulded depth. Triple-expansion engines of 450 I.H.P., and with cylinders of 12 in., 19½ in., and 32 in. diameter respectively, will be provided by Mr. W. V. V. Lidgerwood, Coatbridge, with boilers constructed for a pressure of 180 lbs. per inch, by Messrs. Muir & Houston, Kinning Park.

Granit.—On June 15th there was launched from the shipyard of Messrs. S. McKnight & Co., Limited, Ayr, the s.s. *Granit*, a vessel which has been constructed by the above mentioned firm for Norwegian owners. The *Granit* is a vessel of about 700 tons and is to be fitted with powerful machinery by Messrs. McKie & Baxter, engineers, Govan. She is a vessel of the raised quarter-deck type, and is specially strongly constructed for service amongst ice. After the launch the vessel proceeded to Glasgow to receive her machinery.

Screw-Steamer.—On June 16th Messrs. Russell & Co., shipbuilders, Port-Glasgow, launched a spar-decked screw-steamer of 6,400 tons deadweight carrying capacity on Board of Trade summer freeboard. The dimensions are:—Length, 345 ft.; breadth, 49 ft. 9 in.; depth, moulded, 28 ft. 6 in. The vessel is meantime to builders' account. Messrs. Blackwood & Gordon, Port Glasgow, will supply triple-expansion engines.

Wallsend.—On June 19th there was launched from the yard of Messrs. Murdoch & Murray, Port-Glasgow, a finely modelled steel screw-steamer of the following dimensions:—Length, 165 ft.; breadth, 24 ft.; depth, moulded, 13 ft. 6 in. The vessel is to the order of the Newcastle Wallsend Coal Co., Sydney, and is intended for their coasting trade, and has been built considerably in excess of Lloyd's highest class. The naming of the steamer *Wallsend* was gracefully performed by Mrs. French, Greenock. After the launch the vessel was taken to Greenock, where Messrs. Kincaid & Co. will fit machinery of large power. Captain C. A. Colonna has superintended the construction of the steamer.

Ben Venue and **Ben More**—On June 21st there was launched by Messrs. Hall, Russell & Co., Aberdeen, two trawlers built to the order of the North British Fishing Co., Limited, Aberdeen. The vessels, which were named the *Ben Venue* and *Ben More*, are 160 tons gross register. They will be fitted with triple-expansion engines of 320 I.H.P.

Hopper Barge.—On June 22nd Messrs. W. Simons & Co., Limited, Renfrew, launched complete from their yard the second of three steam hopper barges which they are constructing to the order of the Russian Government. This barge has a hopper capacity of 400 tons and is propelled by one pair of compound surface-condensing engines of 400 I.H.P., steam being supplied from one return multitubular boiler of 120 lbs. working pressure. Cabins for officers and crew are comfortably fitted up on board, and an installation of electric light is provided for night work. The vessel was constructed under the inspection of, and is classed by, Bureau Veritas.

Border Knight.—On June 22nd Messrs. David and W. Henderson & Co., Partick, launched a large steel screw cargo steamer which they have built for the Border Union Steamship Co., Limited, for which Messrs. James Little & Co., Glasgow, are managing owners. The vessel is 360 ft. long, 46 ft. broad, and 28 ft. 5 in. deep; and has a gross tonnage of about 3,900 tons, and will be classed in Lloyd's 100 A1 three-deck rule. She has been fitted with all the latest improvements to insure the rapid and safe working of the large cargo which she has been designed to carry, including powerful winches, and also large derricks at the hatches. The saloon and officers' accommodation is on the fore end of the bridge deck, and a teak chart-room and wheelhouse have been built above this, with a bridge, which will give every facility to the officers in navigating the vessel. A set of triple-expansion engines will be supplied and fitted by the builders, having cylinders 24 in., 40 in., and 64 in. diameter respectively, and a stroke of 42 in. As the vessel left the ways she was gracefully named *Border Knight* by Mrs. A. Scott, of Anan.

Thistle.—On June 23rd the London and Glasgow Engineering and Shipbuilding Co., Limited, launched the twin-screw gunboat *Thistle* for the British Government. This vessel is a sister ship to the *Dwarf*, which has lately been handed over to the Admiralty by the same builders after most satisfactorily completing all her trials. To hasten completion of the ship, the builders on this occasion have fitted the engines, boilers, funnel, masts, &c., on board before launching, the vessel being now practically ready for leaving for a Government dockyard. The Rev Dr. Niven, of Pollockshields, conducted the usual religious service; and the naming ceremony was performed by Mrs. J. D. Milton, Partick.

LAUNCH.—IRISH.

Star of Australia.—On June 24th there was launched from the north yard of Messrs. Workman, Clark & Co., Limited, a large steel screw-steamer built to the order of Messrs. J. P. Corry & Co., London. The christening ceremony was gracefully performed by Miss Ella Corry, second daughter of Mr. John Corry, J.P., London, managing owner of the company, who named the vessel the *Star of Australia*. This is the fifth boat built for Messrs. J. P. Corry & Co. by the builders, and judging from her present appearance there is no doubt she will fully sustain their well-known reputation as designers of large cargo boats. The leading dimensions are:—Length, 440 ft., breadth, moulded, 55 ft.; depth, moulded, 33 ft., with a gross tonnage of 7,370 tons. She has been built under special survey to class 100 A1 at Lloyd's, and to the Board of Trade requirements for a first-class cargo steamer. There are five cargo holds, and, as this vessel is chiefly intended for the Australian and New Zealand trade, three of these are insulated for carrying frozen meat, the system of refrigeration being conducted on the most approved principle. Water ballast is carried in the double bottom extending the entire length of holds and machinery spaces, the after-peak is also arranged as a water ballast tank for trimming purposes. Accommodation is provided amidships on the shelter deck for the captain, officers, and engineers, and the crew is comfortably berthed forward under the shelter deck. The *Star of Australia* will be rigged as a brigantine, the lower masts and yard being of steel. The deck machinery and gear is all arranged for the quickest handling of the vessel, and fast discharge of cargo, and embraces ten powerful steam winches, steam and screw steering gears and patent windlass by the best makers. After the launch the *Star of Australia* was towed to the 100-ton crane to receive her spars and machinery. The machinery has been constructed at Messrs. Workman Clark & Co.'s engine works, and consists of triple-expansion engines supplied with steam from four large steel boilers. Among others the following company assembled to witness the launch, Lord Charles Kennedy, Mr. John Corry and Miss Corry, London, Mr. and Mrs. Robert Corry and family, Mr. and Mrs. Robert Clark, of London, Mr. and Mrs. Gotto and family, Miss Pinkerton, Mr. John Workman, Captain John Simpson, and Mr. MacDonald.

TRIAL TRIPS.

Stentor.—On May 20th a fine steamer, the *Stentor*, left the Mersey for Glasgow, where she loads a portion of her outward cargo for China, and subsequently returns to Liverpool to complete loading. This steamer has been built to the order of Mr. Alfred Holt, by Messrs. Workman, Clark & Co., of Belfast, and has been engined in Liverpool by Messrs. David Rollo & Sons. Prior to her departure for Glasgow a small party proceeded to inspect the vessel, which was lying in the river off the Alexandra Dock. The *Stentor* has two masts, with fidded topmasts, and one funnel. Her principal dimensions are:—Length, 440 ft.; beam, 52½ ft.; and depth, 33½ feet, she carries 3,000 tons of water ballast, a portion of which is put into two deep tanks, each of about 900 tons capacity. One of these large tanks is placed forward of the engine space and the other aft. Her gross register tonnage is 6,700. In some respects she constitutes a new departure in shipbuilding, as in the main hatch pillars have been dispensed with, their duties being taken up by intercostal girder frames between the deck beams, with the hatch coamings forming part of same. This allows of a much larger hatchway, an important feature in vessels engaged in the China trade. The same system of construction is carried out in a modified degree in the remaining portion of the vessel. The sternpost of the vessel represents another novel feature in this class of single-screw steamer; in this case the deadwood is completely cut away, and the usual casting dispensed with, and in its place there has been substituted a wrought steel tube, which forms the after post, and upon which the rudder is hung by one pintle, instead of six as by the ordinary arrangement. The remainder of the stern frame consists of an arched mild steel plate of a U section, to the lower forward end of which is attached a steel casting, forming the post for the rudder. The rudder is of the balanced type, and has been designed so that its displacement is equal to its own weight. Special attention has been paid to the vessel's steering apparatus The cargo outfit is of the most ample description, one of the numerous heavy derricks which have been provided being capable of lifting 35 tons, and she has no fewer than 17 winches. To further facilitate the rapid loading and discharging of cargo she has a complete electric light installation. The machinery consists of a set of triple-expansion engines, having cylinders of 29 in., 50 in., and 82 in., by 60 in. stroke of piston; steam is supplied by two boilers working at a pressure of 180 lbs. per square inch; the main boilers are fitted with 12 Morrison flues, 43 in. internal diameter; they have 9,400 ft. of heating surface and 450 square feet of grate surface, and are fitted with forced draught, the fan being 8 ft. in diameter. The engine-room also contains a number of auxiliary engines, such as circulating pumps, fresh water condenser, feed pumps, &c. A large donkey boiler for the supplying of steam to the deck machinery is placed on the main deck. The engines are fitted with Aspinall's patent governor to prevent racing. At the preliminary run the engines worked with great smoothness, everything giving great satisfaction. The speed realised was 13½ knots, the revolutions being 80.

Kathleen.—On May 25th the steam trawler *Kathleen*, the pioneer ship of the Central Steamship Trawling Co., of Grimsby, went upon her trial trip. This was not only the initial trial trip of a new trawling company, but it was the inauguration of a new era in the fortunes of the town of Selby, for the *Kathleen* was the first product of the Selby Shipbuilding and Engineering Works. Although the ship and the company which own her are registered at Grimsby, she and the five other vessels of the same class which are in course of construction are really the outcome of Selby capital and public spirit. A large company, chiefly consisting of Selby gentlemen, left Hull in the *Kathleen*, and a pleasant voyage was made round the Spurn Lightship, and for several miles along the Yorkshire coast. During the speed trials the vessel ran over 11 knots per hour, and throughout the engines, which were constructed by Messrs. Crabtree & Co., of Yarmouth, gave every satisfaction.

Flora.—On May 27th this steel cargo steamer, built by the Laxevaags Engineering and Shipbuilding Co., Bergen, Norway, went on her trial trip. Constructed to the order of Mr. D. W. Ellerhusen, Bergen, and to Norwegian Veritas highest class, the vessel is of the following dimensions:—Length, extreme, 235 ft.; breadth, 32 ft.; depth, moulded; 15 ft. 8 in. She is 1,032 brutto register tons. The engines are of the triple-expansion type, about 580 I.H.P. and the average speed 10 knots. The ship has a steel deck, double bottom for ballast, peak tank abaft, and is specially built for the timber trade. She is well fitted out in every way, having Emerson Walker & Co.'s patent steam anchor windlass, Fisher's patent steam-steering apparatus, three steam winches, and large donkey boiler. The main stop valve on the boiler is provided with Bower's patent rapid-closing apparatus from bridge, as well as engine room, and answered most excellently during the trial. The vessel and her machinery have been built under the superintendence of Mr. F. Hansen, Bergen. There were present on her trial trip the managing owner, Mr. D. W. Ellerhusen; inspector for Norwegian Veritas, Mr. Sejersted, and a large company of ladies and gentlemen. The trial was in every way a complete success, and the weather everything that could be desired, there being a light warm breeze from the north-west; the sun shining brightly, and reflecting the surrounding mountains very finely in the clear deep waters of the Fjord.

Paris.—On May 27th the trial trip of the s.s. *Paris*, recently built for Messrs. J. & P. Hutchison, Glasgow, by the Irvine Shipbuilding and Engineering Co., Limited, Irvine, took place. A large company of ladies and gentlemen were on board, and the vessel after adjusting compasses ran the measured mile with satisfactory results, a speed of fully 10½ knots, with about 300 tons cargo on board, being obtained. The vessel is 180 ft. by 27 ft. 6 in. by 14 ft. moulded, and has a long poop, bridge, and topgallant forecastle, and cellular double bottom and fore-and-aft peak tanks for water ballast. The net register tonnage is 123 tons, and deadweight 750 tons. The vessel has been built to Lloyd's highest class under special survey, and has been specially designed to meet the requirements of the owner's Continental trade, being similar in design to the s.s. *Hector*, built by the same firm last year for Messrs. Hutchison. The machinery has been supplied by Messrs. Hutson & Son, Limited, Kelvinhaugh, Glasgow, the engines being triple-expansion, having cylinders 14 in., 23 in., and 37 in. by 27 in. stroke, steam being supplied from a steel boiler 10 ft. diameter by 13 ft. 6 in. long, and 160 lbs. working pressure. The owners expressed themselves highly satisfied with the vessel and machinery.

Scandinavia.—On May 27th, the trial trip of this vessel, which has just been completed by Messrs. Carmichael Maclean & Co., shipbuilders, Greenock, took place. The dimensions of the vessel are:—239 ft. 4 in. by 35 ft. by 17 ft. 9 in., moulded, and the gross tonnage is 1,557 tons. The engines are by Messrs. Muir & Houston, with cylinders 19 in., 31 in., and 51 in., and 36 in. stroke, two large boilers and donkey boiler, &c. The vessel is fitted with steam-steering gear, steam windlass, four steam winches, two steam cranes, and with all the latest improvements to Lloyd's class. The *Scandinavia* had 1,773 tons deadweight on board, and the speed attained was fully 10 knots. The vessel has been designed and constructed for the Svenska Lloyd's.

Brisgavia.—On May 31st, previous to departing on her maiden voyage to Baltimore, the above steel screw-steamer proceeded down Belfast Lough on her trial trip; a company, comprising the owners' representatives, the builders, and their friends being on board. The *Brisgavia* has been built and engined by Messrs. Workman, Clark & Co., Limited, of Belfast, and is specially designed for a large carrying capacity, with the most efficient means for rapid discharge of cargo; she is owned by the Hamburg America Line, and during construction was under the direct superintendence of Mr. E. Blumenthal, Mr. Carl van der Smissen, and Mr. W. Brandt. The principal dimensions are:—Length, 450 ft.; breadth, 53 ft.; depth, moulded, 34 ft. 7 in., with a gross tonnage of 6,575. The *Brisgavia* is classed 100 A1 at Lloyd's with special survey mark in the Register, and has all of the Board of Trade requirements for a first-class cargo steamer. She has been subdivided into seven watertight compartments, and carries water ballast in forward and after peaks and right fore and aft in the cellular double bottom. There is also for trimming purposes a deep tank of 560 tons capacity, which may also be used for carrying cargo. On the deck of a long cargo bridge ample accommodation is provided for the officers and engineers; the saloon is tastefully panelled and upholstered, and electric light has been fitted throughout by the Globe Electrical Co. The crew is berthed forward under the forecastle, the space below the poop deck, like that of the bridge, being utilised for cargo. The engines are a powerful set of the triple-expansion type, with all of the most recent improvements. Steam is supplied at a pressure of 165 lbs. from three large steel boilers. Like the hull, the machinery has been inspected during construction by Lloyd's surveyors and finished to their satisfaction. The trial trip was most successful in every respect, and after lunch several toasts were proposed, among which was "Success to the *Brisgavia*," which was proposed by Mr. Workman, coupled with the health of Mr. Blumenthal, representative of the Hamburg America Co., who, in responding, expressed himself as being highly satisfied with the ship and machinery, and hoped this would not be the last ship built by Messrs. Workman, Clark & Co., for the Hamburg America Line. He then proposed the health of the builders, coupled with the name of Mr. Charles E. Allan, the engineering partner of the builders' firm, who suitably responded. This toast was also acknowledged by Mr. R. W. Leyland, of Liverpool, who said that the *Brisgavia* had been originally intended for his firm, but that the contract had been transferred to the Hamburg America Co. He had every confidence in the future of the new steamer as she had been designed with great care and furnished with every modern appliance for working cargo. The last steamer built for his firm by Messrs. Workman, Clark & Co. had been most successful, and he hoped soon to place an order with them for another steamer. Other toasts followed, and the company afterwards separated and later in the day left the steamer by tender, the *Brisgavia* proceeding on her voyage to Baltimore.

Saxonia.—On Saturday, June 3rd, the large new screw-steamer *Saxonia* proceeded to sea for her official trial trip. She is built by the Flensburg Shipbuilding Co., for the Hamburg America Line for their trade between Hamburg and East India. This vessel is 400 ft. in length, by 46 ft. 3 in. beam, by 30 ft. 2½ in. depth, moulded, with long poop and forecastle, built to German Lloyd's class, and is rigged as a two-masted schooner and having accommodation for officers in a large deckhouse on top of bridge amidships and crew in forecastle. She is lighted throughout by the electric light, including cargo lamps, bunker lamps, hand lamps, Suez projector, &c. A double bottom is fitted on the cellular system all fore and aft, and the hull is subdivided by a large number of watertight bulkheads. She is handsomely and comfortably fitted and ventilated throughout in a manner suitable for service in warm climates. The vessel is fitted with steam windlass, ten steam winches, two steam capstans, steam-steering gear, large derrick posts and 15 derricks for 5-20 tons. The engines, which have also been constructed by the Flensburg Shipbuilding Co., are of the triple-expansion type with cylinders 26½ in., 44 in., and 72 in. by 48 in. stroke and two double-ended boilers. During the trial the engines worked in a highly satisfactory manner at 75 revolutions per minute, and a mean speed of 12 knots was attained on the measured mile.

Tullochmoor.—On June 3rd the trial trip of the steamer *Tullochmoor* took place. This vessel is the latest addition to the Moor Line, Limited, managed by Messrs. Walter Runciman & Co., Newcastle-on-Tyne (of which we gave particulars in our Launch columns, June issue, page 133). During the trial the performance of the machinery gave every satisfaction. On the measured mile a speed of 11½ knots was easily obtained without pressing the machinery. After the trial the *Tullochmoor* proceeded in ballast to North America, in command of Captain Moffett, of South Shields.

Una and **Gipsy.**—On June 3rd the speed trials of the steam yachts *Una* and *Gipsy* were run. The former has been specially built by Mr. Claud Macdonald for Mr. R. S. Gilmour, yacht agent, Greenock; the latter was built by Mr. J. A. M'Kie three years ago for his own use; and both vessels have been fitted with duplicate machinery and boilers by Messrs. M'Kie & Baxter, Copland Works, Govan. The engines are of a new type introduced by this firm for small yachts. The yachts themselves each measure 50 tons, and are of similar dimensions. They left Gourock Bay at midday for the Admiralty-checked knot on the Gareloch, and ran the distances in company with practically the same mean speed—11½ miles. The engines are C.S.C., 7 in. by 14 in. by 9 in.; boilers, 6 ft. diameter by 6 ft. long, natural draught, working pressure 125 lbs. Throughout the whole day the machinery worked without the slightest hitch, and to the entire satisfaction of the owners and their representatives.

H.M.S. Upnor.—On June 6th H.M.S. *Upnor*, built by Messrs. J. M'Arthur & Co., and engined by Messrs. Bow, M'Lachlan and Co., Paisley (of which we gave particulars in our Launch columns, May issue, page 91), went down the Clyde to run her official trials which were in every respect up to requirements, and gave entire satisfaction to the Admiralty representatives. On the conclusion of these trials the *Upnor* sailed for Sheerness. The Admiralty were represented at the trial by Mr. S. Rawlings, R.N.; Mr. J. Smith and Mr. Jago, Admiralty overseers; Mr. O. S. Summers, and Captain Hitches.

Mont Blanc.—On Tuesday, June 6th, the fine steel screw-steamer *Mont Blanc*, built by Sir Raylton Dixon & Co., Limited, Cleveland Dockyard, Middlesbro', to the order of the Societe Generale de Transports Maritimes a Vapeur, of Marseilles (of which we gave full particulars in our Launch columns, May issue, page 88), was taken out to sea under the command of Captain Crouzat for her official trials. The vessel has been built under the supervision of M. Terras, naval architect to the company, with Captain Crouzat and M. Balansard as resident ship and engineers' inspectors. Mr. Goodwin, of Liverpool has also superintended on behalf of the owners. A large company were on board during the trials, including M. Lechamp, director of Transports Marine, M. Terras, Mr. E. A. Cohan, Mr. Ward, of Messrs. Elder, Dempster & Co., and Mr. Hall, of the Royal Mail Steam Packet Co.

Ras Mora.—On June 7th the fine steel screw steamer *Ras Mora*, built by Messrs. Wm. Gray & Co. Limited, West Hartlepool, was taken to sea for her official trip. Her owners are Messrs. Grahams & Co., of London, for whom Mr. M. Havelock, of Newcastle-on-Tyne, has acted as superintending engineer. The vessel has been built to Lloyd's highest class, and is of the following dimensions:—Length, over all, 341 ft.; breadth, 47 ft.; depth, 27 ft. 4 in.; with long bridge, poop, and topgallant forecastle. Triple-expansion engines have been supplied by the Central Marine Engine Works of Wm. Gray & Co., Limited, having cylinders 25 in., 40 in., and 65 in., diameter, with a piston stroke of 42 in., and two large steel boilers adapted for a working pressure of 160 lbs. per square inch. The trial was in every way satisfactory, a speed of 11½ knots being averaged, in ballast trim.

Weissenfels.—On June 7th the s.s. *Weissenfels*, which has been built by Messrs. Wigham, Richardson & Co., at their Neptune Shipyard, Newcastle-on-Tyne, to the order of the Deutsche Dampfschifffahrts Gesellschaft "Hansa," of Bremen, went for a very successful trial trip off the Tyne. The steamer is 370 ft. in length by 46 ft. beam and has been built to attain the highest class in Lloyd's Register. She is fitted with quadruple-expansion engines balanced on the Yarrow, Schlick & Tweedy system, which, together with her boilers, have been constructed by Messrs. Wigham, Richardson & Co. This steamer is the eighth vessel built by these builders for the "Hansa" Co., and there are more in course of construction by them. On the trial trip the machinery worked without the slightest hitch, giving satisfaction to all concerned, and driving the vessel at a speed of 12½ knots per hour. The owners were represented by Mr. D. Wulff, their superintendent engineer.

Lakonia.—On June 13th the screw-steamer *Lakonia*, built by the London and Glasgow Engineering and Shipbuilding Co., Govan, for Messrs. Donaldson Bros., Canadian cargo and cattle trade (of which we gave full particulars in our Launch columns, June issue, page 136), went down the Clyde on her trial trip. A large company of ladies and gentlemen were on board. The vessel attained a speed of 13 knots per hour, half a knot over that stipulated for in the contract.

Crewe.—On June 15th the steel screw steamer *Crewe*, built to the order of Messrs. Dent & Co., Newcastle, by Messrs. Wood, Skinner & Co., Limited, Bill Quay-on-Tyne (of which we gave full particulars in our Launch columns, June issue, page 133), proceeded from the Tyne for her official trial. The vessel ran the distance from Tynemouth to Newbiggen and back at the rate of 11 knots per hour, which was considered exceedingly satisfactory, the engines working at full speed all the time without a hitch of any kind.

Oriflamme.—On June 15th this vessel, which has been built by Messrs. Armstrong, Whitworth & Co., Limited, to the order of Messrs. Lane & Macandrew, of London, on behalf of Messrs. Desmerais Frères, of Paris, under the immediate supervision of Messrs. Flannery, Baggallay & Johnson, of London and Liverpool (of which we gave full particulars in our launch columns, June issue, page 133), was taken for trial at sea, when a speed of over 11 knots was obtained. The auxiliary machinery was tried, and after several hours' run the vessel proceeded on her maiden voyage.

Manchester Port.—On June 17th the fine steamship *Manchester Port*, which has been built by the Palmers' Shipbuilding and Iron Co., Limited, Jarrow-on-Tyne, for the Manchester Liners, Limited (of which we gave full particulars in our Launch columns, June issue, page 133), was taken on her official trial trip, and was afterwards delivered to her owners. The *Manchester Port* is the first of two sister ships ordered from the Palmers' Company, the other being the *Manchester Merchant*, which, it is expected, will be put into the water early in the autumn. She has a deadweight cargo capacity of 8,600 tons, and powerful triple-expansion engines with an I.H.P. of 3,500, which on the measured mile gave her a maximum speed of 14 knots, and a mean speed over a series of runs of over 13½ knots.

Otta.—On June 17th the screw-steamer *Otta*, built by Messrs. John Priestman & Co. (of which we gave full particulars in our Launch columns, June issue, page 136), left the Wear for her official trial. Throughout the trial, which was in every way a success, the engines worked with perfect smoothness, and a mean speed of 11 knots was easily maintained, this being considered highly satisfactory.

Cork.—On June 17th the steel screw-steamer *Cork*, built and engined by Messrs. Blackwood & Gordon, Port-Glasgow, for the City of Dublin Steam Packet Co.'s Channel service between Dublin and Liverpool (of which we gave full particulars in our Launch colums, May issue, page 92), went down the Firth on her official trial trip. The company on board, who joined the steamer at Gourock, included—Sir William Watson, managing director, City of Dublin Steam Packet Co.; Mr. E. G. Ferber, superintendent engineer of the company; Mrs. Ferber, and Master Ferber; Mr. D. P. M'Geoch, senior partner of Messrs. Blackwood & Gordon; Mrs. M'Geoch, Mr. F. R. Purvis, partner; Mr. John H. Macalpine, partner; Mrs. Macalpine, Dr. Callaghan, secretary, City of Dublin Steam Packet Co.; Mr. George Gow, New Zealand; Mr. A. Forsyth, secretary and manager Dublin and Glasgow Steam Packet Co.; Mr. John Lyall, superintendent engineer of Clan Line; Mr. Bevis and Mr. Taylor, Liverpool. After cruising about the entrance to Loch Long, Holy Loch and the Firth, the steamer, which was loaded with a deadweight cargo of 620 tons, proceeded to make a succession of four runs between the Cloch and Cumbrae Lights, when a mean speed of about 15 knots was attained, which is in excess of requirements. After lunch, which was served in the spacious saloon on the final run, Mr. D. P. M'Geoch presiding. After the toast of "The Queen" had been heartily pledged, the chairman gave that of the company and her owners, coupling it with the name of Sir William Watson, whose health he also proposed. In doing so he remarked that the *Cork* was the sixth vessel built by his firm for the City of Dublin Steam Packet Co. The trade *between Dublin and Liverpool* since they first did business with the company had increased very much, and was still increasing, and he hoped the day was not very far distant when the seventh vessel would be laid down in the Castle Yard, Port-Glasgow. The City of Dublin Steam Packet Co. was represented there that day by Sir William Watson. They were glad to hear of the honour lately conferred upon him, and they congratulated him upon the position which he now occupied. Sir William took a great interest in all the vessels of the company, and he thought they might predict an era of prosperity for the City of Dublin Steam Packet Co. In responding to the toast, Sir William Watson remarked that the *Cork* was very much similar in respect of fittings to the other vessels built by Messrs. Blackwood & Gordon for his company, but increased passenger accommodation had been provided. They had great reason to be pleased with the way in which Messrs. Blackwood & Gordon had fulfilled their contracts, and from what he had seen that day of the *Cork* he was quite satisfied that her speed would surpass that of her predecessors. Sir William then proposed the toast of "The Builders," remarking that they had spared neither time nor energy in producing the ship which they were asked to produce, and he confidently said that they had done so. Mr. Purvis responded. "The Officials of the Company" was afterwards submitted by Mr. Macalpine, and replied to by Dr. Callaghan. The latter thereafter proposed the toast of "The Ladies," to which Mr. Wedgwood responded. ~~After landing the guests at Gourock~~, the *Cork* proceeded to Liverpool under the command of Captain Memry.

West Point.—On June 17th the large new steamer *West Point*, built for the Norfolk and North American Steam Shipping Co., Limited, by Messrs. Robert Stephenson & Co., Limited, left Hebburn for her official trial at sea. The vessel is a heavy one for general provision cargoes, and will trade between London and Philadelphia regularly with the other "Point" liners of the firm, for whom Messrs. Simpson, Spence & Young, of Guildhall Chambers, Newcastle, are the managers. The *West Point* is an excellent type of cargo carrier, and has a very smart appearance. Her dimensions are:—Length between perpendiculars, 375 ft.; beam, 50 ft.; and depth from top of steel shelter deck, 38 ft. Her carrying capacity is 7,500 tons. There is good accommodation for the crew and cattlemen in the forecastle, representing over 60 hands when 30 or more cattle attendants are voyaging with beasts. There is a long shelter deck amidships, with steel deck, and on the top of this in a spacious deck-house is excellent accommodation for the commander, officers, and engineering staff. Beneath the shelter deck is accommodation for a large number of cattle. The West Point is classed 100 A1 at Lloyd's on the three-deck principle. She has two complete steel decks in addition to the steel shelter deck already mentioned. She has also a double cellular bottom fore and aft for water ballast, and in addition a deep ballast tank of 1,000 tons capacity. The deck fittings for working the cargo are extensive, and the principal hatches lie athwartship more than fore and aft, to enable loading on one side of the vessel whilst discharging is going on at the other side, if necessary. She has nine steam winches, steam steering gear by Messrs. Donkin & Co., and steam capstans by Messrs. Emerson, Walker & Co., and to work these is a large donkey boiler of the marine type. To support the principal cargo-lifting gear there has been fitted six ventilating derrick posts, in addition to the mast derricks. The vessel is rigged as a schooner, and has telescopic top-masts to enable her to pass river bridges. Her engines, which have also been built by Messrs. Robert Stephenson & Co., Limited, are triple-expansion, with cylinders 26 in., 43 in., and 71 in., and 48 in. stroke, and all take steam from two large single ended boilers of 1,000 H.P. each. The working pressure is 180 lbs., and the boilers are fitted with Howden's patent forced draught. The engines are 400 H.P. or 2,000 I.H.P. The trial was in every way satisfactory, and speeds, not only on the measured mile, but also on long point to point runs, were obtained equal to 11¾ to 12 knots. The *West Point* is the first of two vessels of the same class which the builders have in hand for the owners. The vessel is commanded by Captain David Jenkins, an experienced Atlantic navigator.

Gothland.—On June 20th the steamer *Gothland*, of the Liverpool and Hamburg Co.'s service (Messrs. Donald Currie & Co.), is an old and tried boat, which has been in the run between Liverpool and Hamburg for many years, and, though her passenger list is necessarily limited, those who have gone to the Continent in her have had every reason to be satisfied with their choice of a steamer, for whilst not excelling in point of speed, she has earned a reputation for being as comfortable a boat to travel in as any leaving the port. Her owners have, however, for some time thought that in point of speed an improvement might be made, and with this view placed her in the hands of Messrs. David Rollo & Sons, the well-known engineers and ship repairers, of Fulton Engine Works, Liverpool, to have her engines converted, and in order that such other work as was necessary should be carried out. In opening out the vessel to re-engine her, the Messrs. Rollo found that though she was 28 years old, her structure was almost as good as when she was first placed on the service. In the hands of these engineers then the *Gothland* has had her boilers and engines renewed, and advantage was also taken to bring her up to date. All worn or defective parts were removed and newly fitted. She was supplied with a completely new deck, while the winches and cargo gear were also up to as perfect a condition as possible, two new winches by Messrs. John H. Wilson & Co., Liverpool, being fitted. The new machinery is of the triple-expansion type, the cylinders being 20½in., 34 in., and 55 in., by 39 in. stroke, with a boiler pressure of 265 lbs. Steam is supplied from two large single-ended steel boilers, each 13 ft. 3 in. diameter by 9 ft. 8 in. long. The total heating surface is 3,100 square feet, the grate surface being 97 ft. There is also a large donkey boiler on deck for supplying steam to the deck machinery. On her trial trip the engines worked very smoothly, and gave every satisfaction to the owners' representative on board, developing about 1,000 H.P., with 66 revolutions per minute. The entire absence of vibration during the trip was commented upon. On the outward run between the Bar Lightship and the North - west Lightship, the vessel showed an average speed of 12¾ knots, and the speed as noted from time to time showed between 12 and 13 knots. It may be stated that the *Gothland* is the second vessel that Messrs. Rollo re-engined for the Castle line, and they have shown how such a vessel can be brought up to modern requirements. The result of the trial justifies the wisdom of the owners not only in planning the conversion, but also in their choice of a firm to carry out such work. The *Gothland* is a steamer of 1,482 tons gross, her dimensions being 252 ft. long, 32 ft. beam, and 16.9 depth of hold.

Ping Suey.—On June 20th the steel screw steamer *Ping Suey* proceeded down Belfast Lough on her trial trip. She has been built to the order of the China Mutual Steam Navigation Co., of London, by Messrs. Workman, Clark & Co., Limited, Belfast, and is the seventh vessel they have constructed for these owners. The *Ping Suey* has been designed for the Eastern trade, and built under Lloyd's special survey for the 100 A1 class; she is also provided with a Board of Trade passenger certificate. The dimensions are:—Length, 450 ft.; breadth, 53 ft.; depth, moulded, 34 ft.; with a gross tonnage of 6,457, and deadweight carrying capacity of 9,200 tons. The vessel is rigged as a two-masted schooner, the masts being telescopic, to suit the Manchester Ship Canal; she is sub-divided into eight water-tight compartments, and water ballast is carried throughout the entire length in a cellular double bottom, the peaks at extreme ends and a deep midship tank being also adapted for carrying water for trimming purposes. The saloon, captain's, officers', and engineers' state-rooms are on the bridge deck amidships, and the native crew are berthed aft under the poop deck, the spaces below bridge and forecastle decks being utilised for carrying cargo. The machinery, consisting of triple-expansion engines, two large steel boilers, and an auxiliary boiler, has been constructed at Workman, Clark & Co.'s Engine Works, and is fitted with the most modern improvements. On trials on the measured mile the speed of the *Ping Suey* proved highly satisfactory. A company of the owners and builders were on board, and during the day enjoyed the cruise in Belfast Lough, and at luncheon Mr. Gulland, managing director of the China Mutual Co., expressed himself well satisfied with the manner in which the steamer has been completed. The construction of the vessel has been under the supervision of Captain John S. Hogg, commodore of the China Mutual Co.'s fleet. After the trials the *Ping Suey* proceeded to Glasgow under the command of Captain de la Parelle, where she will load for her maiden voyage to China and Japan.

Upada.—Lately the steamer *Upada*, built to the order of the British India Steam Navigation Co. by Messrs. A. & J. Inglis, Glasgow, completed her trials on the Clyde. The *Upada* is of 5,600 tons gross register, and carries a deadweight cargo of 8,000 tons. She is intended chiefly for the company's trade from Calcutta to Mauritius, and in the season to Australia, being adapted for the conveyance of a large number of horses. Although denominated a cargo ship, she has a Board of Trade passenger certificate, and can be readily converted into a trooper or passenger steamer. The trial was in every way successful.

Arcadia.—Lately the new screw-steamer *Arcadia*, built and engined by Messrs. John Readhead & Sons, South Shields, had her official trial trip, and on a series of successful runs, averaged a speed of 11 knots.

Reviews.

Year-Book of the Scientific and Learned Societies of Great Britain and Ireland, 1899. London: Charles Griffin & Co.

We have received a copy of the sixteenth annual issue of this most useful work of reference. It treats of its subject most exhaustively. The societies are grouped for convenience under some fourteen heads, according to the subject matter with which they are associated. Information as to the names of their officers, the dates of their meetings, their publications, with the amount of their entrances and subscriptions, details of their work generally, the papers that have been read during the year just concluded, are all afforded, and so far as we have been able to check it, the matter set out is not only exhaustive but also singularly accurate and up to date. Though the system of grouping the various bodies by subjects would appear to render the information contained in the volume sufficiently easy of access, there is an additional means of getting at any required point in the excellent index which is appended to the book. It may be said that the volume is a complete abstract of the work of the scientific year, and as the series lengthens each issue acquires an additional value from its relation to those which have gone before. We find in the set a complete history of this part of the work of scientific elucidation and exposition which has been so characteristic of the closing years of the present century.

The Mechanical World Pocket Diary and Year-Book for 1899.

Pressure on our space has prevented us from noticing earlier this amongst certain other annual publications of considerable value to the working engineer. We have on previous occasions noted the valuable features of this little work. The present issue again contains further additions to the information offered. The subject of oil engines is now somewhat exhaustively treated, and a number of tables dealing with the calculation of weights have been added. These are likely to prove of value to practical men. The little book now contains some 220 pages of well-printed matter. Yet it is still of a form convenient for carriage in the pocket.

Messrs. Stern Brothers of 57, Gracechurch Street, London, have an exhibit at the Greater Britain Exhibition in the West Australian section, which will undoubtedly interest all those interested in lubricants. This exhibit comprises the various specialities which they manufacture such as their Sternoline Lubricant for Stauffer and Automatic Lubricators, Fram Lubricant for Motors, Sternoline Bricks for tunnel bearings of steamers, open bearings, and roll necks, high-class Dynamo and machinery oils, also specimen of their Paraffinum Liquidum B.P. 98, and Paraffinum Molle B.P. 98, the former being the most highly refined mineral oil in the market, being absolutely water-white, and entirely free of taste, smell, and impurities. They have four factories in which the manufacture of the above and other lubricants is carried on.

Dredger for Japan.—Messrs. W. Simons & Co., Limited, Renfrew, have received an order to construct a powerful Twin-Screw Hopper Dredger for Japan.

The Marine Engineer.

LONDON, AUGUST 1, 1899.

THE summer meeting of the Institution of Naval Architects, held at Newcastle-on-Tyne, has been replete with papers, communicated by the members, full of interest to engineers and members of the allied professions, and we only regret that our available space will not admit of dealing with them or reproducing all we would wish *in extenso.* Dr. Francis Elgar, vice-president of the institution, has dealt in a most instructive and interesting fashion with the distribution of pressure over the bottom of a ship in dry dock and over the dock blocks, basing his observations upon a serious accident to the North German Lloyd steamship *Fulda.* This is not the first accident of the kind, and, seeing the increasing size and weight per foot of length of steamers, the matter is of increasing importance to all concerned. Where the forward overhang of the vessel is great, as was the case in the *Fulda*, not only will a certain number of the forward blocks be entirely useless for support, but when the vessel lies in assumed equilibrium upon the remaining blocks, there will be no pressure upon blocks that are more than twice the distance abaft the centre of gravity of the vessel that the foremost block is before it. If it is assumed, as in the case of the *Fulda*, that the forward overhang is 5-16ths of the length, this would remove pressure from the after-blocks to the extent of 1-8th the length of the vessel from the after-block. This leaves only 9-16ths of the blocks distributed over the whole length of the vessel as contributing to carry the whole weight. The increase of pressure also upon the forward block by reason of a considerable overhang will be vastly increased as compared with the mean pressure calculated as if each block distributed over the whole length of the vessel bore its equal quota. With 5-16ths overhang the increase would be nearly four times the mean. These results, however, are upon the assumption that the wood-caps are only stressed within their elastic limit, so that each of the remaining blocks may properly come into bearing so as to carry their own proportion of weight. But when the caps of softwood and greenheart are of small depth, and the accumulation of pressure at the forward block is excessive, due to great overhang, the forward blocks may be all stressed beyond their elastic limit, and the maximum pressure on individual blocks may again be much increased beyond the stress above indicated, and it will be no matter for wonder that the blocks should be thus individually broken down in succession. It is obvious that the practice of fitting intermediate blocks where there is overhang is very effective in preventing the possibility of such accidents as that of the *Fulda* before the blocks under the rising keel can be made up, and it is recommended that the doubling and trebling of blocks near the commencement of the rise of the keel is most necessary to avoid liability to such accidents as that of the *Fulda.*

APPARENTLY the possibilities of forced draught have not yet been exhausted. Mr. Nelson Foley makes a suggestion, and gives details of a system of forced draught which is new as far as we are aware in its mode of application. He employs hollow fire-bars with a mushroom head protecting partially radial orifices, through which is injected the air blast which it is believed also induces an increased indraught from the external atmosphere between the bars. The bars are connected to an air chamber, or box, under the front of the furnace, or two of these air boxes may used as the front and back of the furnace. It has been found by careful experiment that combustion increases on this grate by increase of air pressure from 5·32nds of an inch to 3-16ths of an inch, and with the latter pressure the rate of combustion was 22·3 lbs. per square foot of grate area when stoked for maximum combustion. This result is so good that the arrangement appears to require serious attention. It offers the advantage that the stokehold is open and without encumbrance, and a good draught through it is induced by the forced air-jets. The bars during forced draught do not suffer at all, which might be expected, and clinker does not seem to adhere to the bars, but is readily removed. The bars were also run at natural draught to test their durability, and after 10 days' continuous run no more than normal injury was found to have been sustained, and only a few air holes were found to be choked. We think this system promises well.

MR. G. B. HUNTER's paper upon large Atlantic cargo steamers is extremely valuable as bringing up to date the unrivalled experience of his firm in the new conditions of construction of the present large Atlantic cargo steamers which have really only run since 1894. It is remarkable that until 1895 there were no more than four British cargo steamers of more than 6,500 tons gross register (always excepting the *Great Eastern*), whilst in March, 1899, no less than 54 cargo steamers of 6,000 tons gross register and upwards were building in British yards; and at present of merchant steamers of 10,000 tons gross register and over (cargo and passenger), there are 18 building in British yards (including the *Oceanic*, about 17,000 tons), nine in German shipyards, and two in French shipyards. The Atlantic leviathans have thus come to stay, and are apparently justifying their existence on economical and commercial grounds. Mr. Hunter gives what he considers the essentials for large cargo steamers for the Atlantic. There should not be more than three complete decks, including a shelter deck, with a partial fourth deck in the forehold only. With a complete shade deck there is no need for the further addition of a long bridge-house either for space or safety, and such further erections are undesirable, and should be limited to houses for the officers and steering and chart-house, with pilot bridge 15 ft. above it. Steel decks need not be sheathed with wood, nor should wood-sheathing be fitted on the double bottom. Very few Atlantic cargo steamers have sufficient water ballast, owing to the frequent necessity of making the outward passage in ballast. The 500 ft. 12,000 tons deadweight steamer should have not less than 4,000 to 4,500 tons of water ballast, of which 1,700 tons can be carried in the double bottom tanks, and 2,000 tons in two "deep tanks," one aft and one forward, and 800 tons in 'tween deck tanks. Large peak tanks in the extreme ends of the ships are undesirable as promoting pitching vibrations and uneasy motions. As to propelling machinery considerable power is required for the Atlantic in view of head winds and severe weather. A point of great difficulty is the question of the propeller shafting. It is recorded that 173 steamships were disabled in 1898—mostly in the Atlantic—by fracture of shafting. It is stated that 53 similar accidents occurred in April, May, and June this year. This can only be regarded as highly unsatisfactory. The causes are much debated. It is suggested that with new triple engines, there being less shock and danger to the engines when racing in ballast as compared with the old compound engines, captains and engineers are less careful as to reduction of speed, and are getting more accustomed to running under such conditions. The strain on the propeller shaft remains, however, the same as before, and if running in ballast and maintenance of speed is to be continued, Mr. Hunter recommends an increase of strength in propeller shafts 100 per cent. above present rules. He proposes also that all vessels of 10,000 to 12,000 tons should have duplicate engines and screws, giving smaller screws for running in ballast besides safety in case of breakdown of one; and this should be done in spite of other slight disadvantages appertaining to twin engines as compared with single engines. Mr. Hunter concludes with some valuable information as to the latest methods in his firm of building large steamships under glass shipsheds with travelling cranes running the whole length. He finds the result much more economical in building and in the saving of staging and long shores, as the columns supporting the roof are freely used as abutments for the shores.

Information obtained by direct experiment upon the frictional resistance of the ordinary collar-and-ring thrust-block, and the saving to be effected by the use of roller-bearings in such a block, has been communicated by Herr F. von Kodolitsch. He constructed a thrust-block suitable for an engine developing 600 I.H.P. at 136 revolutions per minute to travel a vessel at 12 knots per hour. From these data he deduced the necessary thrust upon the block under these conditions, and then weighted on a horizontal table the thrust-block placed vertically to correspond to these conditions. The thrust-block was then driven by an electrical motor up to the desired speed of 136 revolutions, and the H.P. developed by the motor for driving the weighted block measured its frictional resistance after due allowance for the efficiency of the motor and gear, which was also tested for each experiment. In this way the block, being adapted to drive one way on roller-bearings, and the other way on white-metal rings and collars, it was found that under these diverse conditions the block absorbed in friction 2·4 H.P. when running on the roller-bearings lying in a bath of lubricant, and 29·75 H.P. when running on the rings and collars in the ordinary way. This saving appears worth obtaining by the use of roller-bearings. Though the anti-frictional value of such bearings has long been known, the practical difficulty arises not in their application, but in their tendency to irregular wear, which Herr Kodolitsch did not touch upon.

The past month has been signalised also by the meeting at the Fishmongers' Hall of the International Maritime Conference, under the able presidency of Mr. Justice Phillimore, whose experience in the legal aspect of maritime disputes is so wide and general. By unanimous consent Dr. Sieveking was elected as vice-president during the unavoidable absences of the president, owing to his judicial pressure of business. The questions exhaustively discussed were the relative apportionment of damage between two vessels in collision where both were to blame. After settlement of the relative apportionment of damage the next question considered was, Should the principle of proportional apportionment of damages apply to the cargoes as well as to the ships, or should the cargo-owners and other third parties be entitled to proceed jointly and severally against the two vessels? After much general discussion, injury to life and limb was dissevered from the question of damage to cargo and property in the vessel, the former consideration being evidently a more thorny one than the latter. A further important discussion was upon the point whether the responsibility of shipowners be personal, and, if so, should it be limited, and how; or should it be confined to the ship and freight? Upon this point there seemed to be much diversity between the Continental and the British view of the advisability as to such limit, and a long and very full discussion ended in two resolutions: first, that the shipowner shall be permitted at his option to discharge his liability either (*a*) by abandoning ship and freight, or (*b*) by paying a sum of money calculated upon the tonnage. This resolution has no reference to claims for loss of life or personal injuries. The second resolution was a lament upon the diversity of national laws regarding collisions at sea, and an invitation to Her Majesty's and other Governments to institute a full inquiry into the whole subject.

At the moment of going to press we are shocked and startled by a terrible disaster befalling a destroyer, the *Bullfinch*, upon its full-speed trials in the Solent. It is believed that the breaking of a connecting-rod smashed a high-pressure cylinder or cover—with the instant release of vast volumes of boiling water and steam into the confined engine-room and stokehold. The results were most disastrous, causing immediately the death of eight men and serious injury to six others, some of whom will probably not survive. Nothing can be said at present as to the probable causes of this grave disaster, and we can but add our mite to the public sympathy for the lives cut short in so untimely a manner and for the sufferings of the injured. We have again to press emphatically upon the Admiralty that the use of self-closing steam-check valves in the steam-pipes close to the boilers, such as we discussed and illustrated in our issues of February and March, 1898, would have served to prevent the chief part of the fatalities resulting from this accident, however caused.

ON THE BOILER ARRANGEMENTS OF CERTAIN RECENT CRUISERS.*

By F. T. Marshall, Esq., Member.

During the past few months the company with which the writer is connected have completed the machinery of several vessels of the cruiser class, which differed so noticeably in the type of boiler fitted that he thinks some comparison of the systems used, and some description of the arrangements adopted, may prove of interest to the members of the institution.

The vessels referred to are H.M.S. *Andromeda*, built at H.M. Dockyard at Pembroke; H.R. Portuguese M.S. *Don Carlos I.*, built at Elswick; and H.I. Chinese M.S. *Fui Tien* and *Ha Chi*, sister vessels, also built by the Armstrong Co.

At the end of the paper a comparative table will be found, giving particulars of the power, heating surface, grate area, space occupied, and weight of the boiler arrangements of these vessels. Outline sketches of the boiler-rooms and of the boilers themselves are also given.

Owing to the courtesy of Sir John Durston, the writer has been able to add similar information regarding H.M.S. *Hermes*. This vessel is one of the latest second-class cruisers in Her Majesty's service, and in size more nearly resembles the *Don Carlos* and *Hai Tien* than the *Andromeda* does.

Particulars are also added of H.M.S. *Æolus* and *Pallas*, which are typical second and third-class cruisers with cylindrical boilers.

The boiler installation of the *Andromeda* is shown in Fig. 1, and consists of thirty Belleville boilers fitted with economisers. These boilers are arranged in four watertight compartments, there being a separate funnel to each group.

The stokeholds are fitted with the necessary arrangements for closing in, fans being supplied to work them under pressure, if necessary. Each boiler-room is also supplied with a furnace air-pumping engine to supply air in jets above the fire-grates and also in the combustion chamber under the economiser.

The arrangement of the boilers of the *Hermes* is shown in Fig. 2, and consists of 18 Belleville boilers with economisers. These are arranged in three watertight compartments, each group having its own funnel.

The boiler arrangement of the *Don Carlos I.*, shown in Fig 3, consists of twelve Yarrow type boilers arranged in two watertight compartments with two funnels. It is of interest as being the largest installation of small tube water-tube boilers which has yet been tried at sea, and it may here be mentioned that all the trials passed off without the slightest hitch and no difficulties were experienced.

The forced draught fittings are on the closed stokehold system, there being four fans to each boiler compartment. In addition to the air which passes through the automatic draught plates at the front of the grate, a further air supply is given to the sides and back of the grate, by means of automatic flaps fitted in a screen built closely round the boiler front and fitting to the floor, sides, and top of the stokeholds.

The boiler arrangement of the *Hai Tien* and *Hai Chi*, shown in Fig. 4, consists of four double-ended and four single-ended cylindrical boilers. These are placed in three watertight compartments, two double-ended boilers in the forward and aft compartments, and four single-ended boilers in the midship compartment. There are two funnels, two double-ended and two single-ended boilers being led into each.

The forced draught arrangements are on the closed stokehold system, with four fans to each compartment.

It will be seen that the boilers of these vessels furnish examples of three of the principal types of warship boilers, viz.: (1) the large tube water-tube type, represented by the Belleville boiler; (2) the small tube water-tube type, represented by the Yarrow boiler; (3) the cylindrical fire-tube boiler.

Detail Construction.

As to the detail construction of the types under consideration, that of the Belleville boiler has been already fully described in various papers read before the Institution. Fig. 5 shows the general design of the economiser type of this boiler as fitted on board the *Andromeda*. The tubes, which are of solid-drawn steel, galvanised externally, are 4½ in. diameter in the generator elements, and 2¾ in. diameter in the economiser elements, in the boilers of the *Andromeda*. In the *Hermes*, the boilers of which are shown in Fig. 6, the generator tubes are 4 in. diameter and the economiser tubes 2¾ in. diameter.

The Yarrow type boilers of the *Don Carlos* are shown in Fig. 7. As some departures have been made from the usual Yarrow type, some description of the construction and method of it may be of interest.

The method of manufacture is to completely rivet up the steam drum, the tube holes being previously all drilled through a cast-iron template. The wing pocket tube plates are also drilled to template and are then erected together with the steam drum on a triangular frame.

The boiler is then tubed in the ordinary way and the tubes expanded and bell-mouthed, after which the ends and bottom plates of the wing pockets are riveted in place. This completes the part of the boiler subjected to pressure. The tube ends are readily accessible in the finished boiler by means of ordinary manholes in the steam drum and water pockets. These manholes are flanged inwards and fitted with ordinary internal

---

* Read at the Summer Meeting of the Fortieth Session of the Institution of Naval Architects, July 19th, 1899, the Right Hon. the Earl of Hopetoun, G.C.M.G., in the chair.

TILDEN FOUND

doors. The tubes are of solid-drawn steel, the two rows next the fire being 1⅜ in. diameter, ·128 thick, and the rest 1⅛ in. diameter, ·104 thick. It will be noticed that all the tubes are straight, except the two rows next the fire, which are slightly curved. The reason for the adoption of this curvature is that these front rows of tubes, which are subject to higher temperatures and more sudden changes of temperature than the rest of the tube surface, have in some cases, when initially straight, shown a tendency to spring against each other in varying directions. This obstructs the uniform flow of the gases, besides being mechanically objectionable.

By slightly curving the outer rows as shown, any springing takes place in a known and definite direction, and does not, therefore, have the effect above indicated, whereas the curvature is so slight that it does not appreciably interfere with cleaning or inspection.

The boilers shown are fitted with straight external downcomer stay tubes, and, in addition to this, a certain number of tubes at each end of each pocket are baffled off from the fire to ensure them working as permanent downcomers, and, as far as possible, maintaining a uniform direction of circulation in the boilers.

The tubes are arranged in the tube plates with several gaps on the fire side. The object of this is to throw a greater number of tubes into actual contact with the fire, and thus somewhat relieve the outer rows, which are very severely worked. This arrangement also somewhat increases the combustion space.

There are no stay tubes actually distributed throughout the tube plates, these not being found necessary, besides being objectionable, owing to their greater thickness, and consequent different expansion to the adjacent tubes. That they are unnecessary is, the writer submits, shown by the following experiments made upon this point:—

A tube 1⅛ diameter, ·104 thick, standing ⅛ in. above tube plate, and merely expanded in, resisted a load of 4·6 tons before being drawn out. A similar tube, standing 1-16th in. above, required 4·22 tons, and a third just flush was drawn out by 3·3 tons load.

It will be seen that the strength of a large nest of these tubes is enormous, and is further increased by all the tubes being bell-mouthed inside. This latter operation also has the effect of improving the flow of water into the tubes, and thus assists circulation.

A matter of great importance in boilers of this type is the design of the casing work. These casings have to withstand not only high temperatures, but many sudden changes of temperature. They require to be stiff to maintain their form, but must be arranged to accommodate themselves readily to varying conditions of strain produced by heat, and, above all, they must remain airtight.

The form of casing shown in the photographs has been found to give no trouble whatever. It will be seen that this is arranged in panels, any one of which can be readily removed for examination or overhaul of the part of the boiler at which it is situate. The form of flange attachment adopted gives great freedom for expansion and contraction, besides stiffening the structure.

As to the cylindrical boilers, these are shown in Fig. 8, and are of the usual form and proportions adopted for vessels of similar type. There is a separate combustion chamber to each furnace. The tubes, which are of lapwelded steel, are 2½ in. diameter, and all fitted with the Admiralty cap ferrule in the combustion chamber end.

FEED ARRANGEMENTS.

This is always an important matter, but specially so in water-tube boilers holding comparatively small quantities of water, and it becomes most desirable that the feeding should be automatic.

The system adopted in the *Andromeda* is that generally used with Belleville boilers. Two large feed tanks, holding in all 13 tons of water, are placed high up in the engine-room. These large tanks are necessary, owing to the variable weight of water in these boilers when working at the different rates of evaporation due to sudden changes of speed of ship.

The feed-water is taken from the hot well by special pumps, and is pumped through the filters into the feed tanks. Thence it flows to the boiler feed-pumps, and is delivered into the boilers through Belleville feed regulators, which control the speed of the pumps by means of pressure produced by the inlet valves, which are actuated by a float arrangement.

In the case of the *Don Carlos* the feed-water is pumped by the air-pumps into two vertical feed-tanks, each holding 3¼ tons of water. Thence it flows by gravity through the feed filters to the feed-pumps in the stokeholds, of which there is one to each boiler.

The pumps are of duplex type, and are controlled by Mr. Yarrow's special arrangement, the steam supply to the pumps being taken from a guarded pipe just above the normal water level, so that, if the water is high in the boiler, it enters the pump cylinder, and so checks the speed of the pump.

The fitting is extremely simple, and worked admirably throughout the trials, and also when steaming at low speeds in the river, &c. It has, however, the objection of being somewhat wasteful, and is hardly so sensitive as the arrangements which check the feed supply direct.

The feed system used for the cylindrical boilers is for the air-pumps to deliver to a vertical tank in the engine-room, holding 4¾ tons of water. From this it flows by gravity to the boiler feed pumps, which are in the stokeholds, which deliver through the filters into the boilers, the feed regulation being by hand.

SPACE AND WEIGHT.

On looking at the floor area occupied by the three types of boilers, it will be seen the H.P. developed per square foot under natural draught is approximately the same. In other words, that for continuous steaming practically the same power may be obtained from the same size of boiler-room whichever of the three systems is adopted.

If, on the other hand, the maximum powers are considered, the advantage of both the Yarrow and the cylindrical type is very marked, as by the use of forced draught very much higher powers may be developed for short periods.

Again, looking at the heating surface contained in the various boilers per square foot of floor space, it will be seen that the Belleville and cylindrical types, which have about the same amount, have both substantially less than the Yarrow system. This seems to indicate that the loss of economy of the Yarrow type, when moderately forced, will not be very serious, whereas the cylindrical boilers can only be forced at a sacrifice in economy. This is borne out by experience, although at low powers the cylindrical type is more economical.

On comparing the grate area per square foot of floor space, the Belleville type possesses a substantial advantage. This is still more evident if comparison be made on the basis of 6 ft. 3 in. firebars, and there is an unquestionable loss of efficiency in stoking longer bars for long consecutive periods.

The large grate area on moderate length of bar obtained on a given floor space is one of the strong points of the Belleville type, and makes it an excellent boiler for maintaining high sea speeds for considerable lengths of time. This great gain is partly discounted by the loss of efficiency if the stoking is indifferent.

Owing to the tubes being so close down to the grates, the fires have to be kept very thin, but very uniform, to ensure good combustion. This trouble has been minimised by the introduction of a combustion chamber in the economiser variety of the Belleville type, but it is still a real one, and in evaporative trials a change of stokers may easily affect the evaporation per pound of coal to the extent of 10 per cent. This difficulty is noticeable also in the Yarrow type, but to a less degree, owing to there being much more space for combustion before the gases come in contact with the tube surface.

Next, dealing with the question of boiler-room weight, we find that, on the basis of the natural draught power, the two water-tube types are substantially lighter than the cylindrical type, the Yarrow type being the lightest.

On the basis of the maximum power the advantage of the Yarrow type in this respect is enormous, whereas the Belleville type is not materially lighter than the cylindrical, owing to the fact that it is not forced.

Thus, on a given weight, the Belleville type will develop, with natural draught, and for long periods, approximately the same power that the cylindrical type will develop for short periods of a few hours under extreme forced draught. Also, on the same weight, the Yarrow type will develop 14 per cent. more than the Belleville for long periods, and 78 per cent. more for short periods. Again, comparing the Yarrow with the cylindrical, it is seen that it will develop 50 per cent. more power for long periods, and 65 per cent. more for short periods, on a given weight.

The above comparisons are based upon total boiler-room weights, including water in boilers plus water in the feed and also such fittings as reducing valves, separators, &c., form an intrinsic part of the boiler systems.

separate weights of boilers and funnels, water, and boiler-accessories are also given, and it may be noticed how vely high the weight of accessories is in the case of the ville type, owing to the numerous special fittings which part of this system.

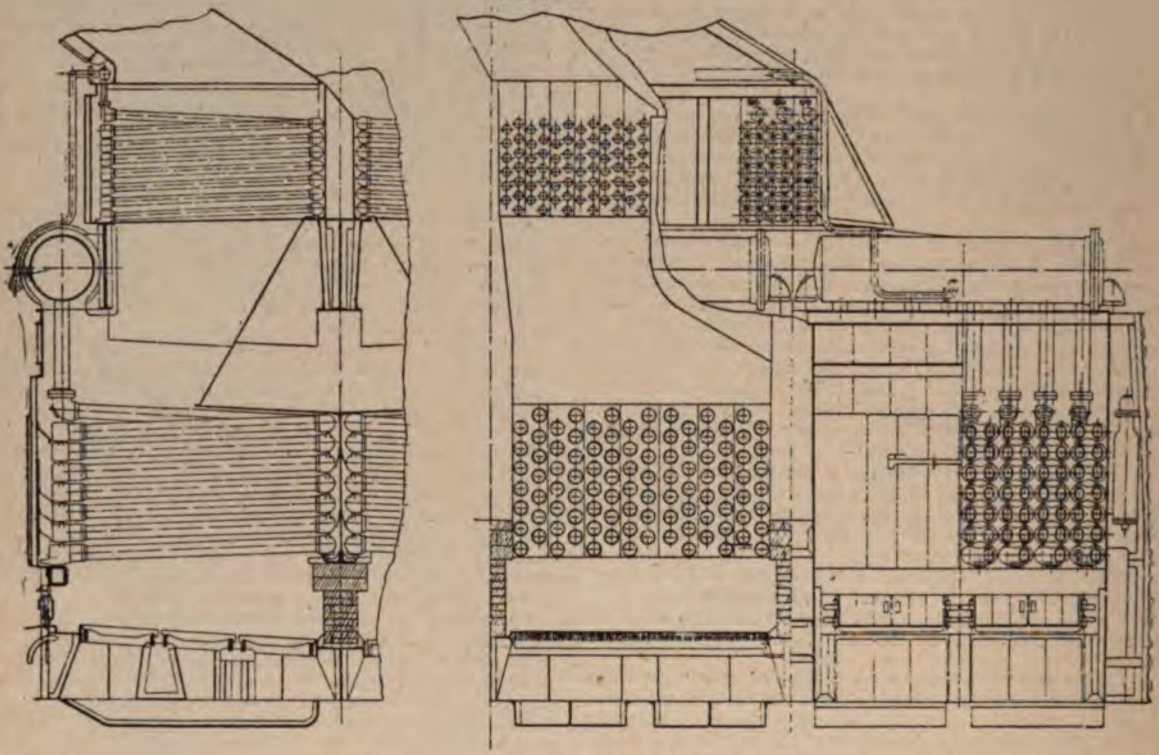
FORCED DRAUGHT.

A crucial point in the above comparisons of space occupied and weight is the question of how far forced draught can safely be used in the usual exigences of service, or even in the extreme case of war.

As to the Yarrow boiler, the writer submits that, as far as the boilers are concerned, this type may safely be forced to an

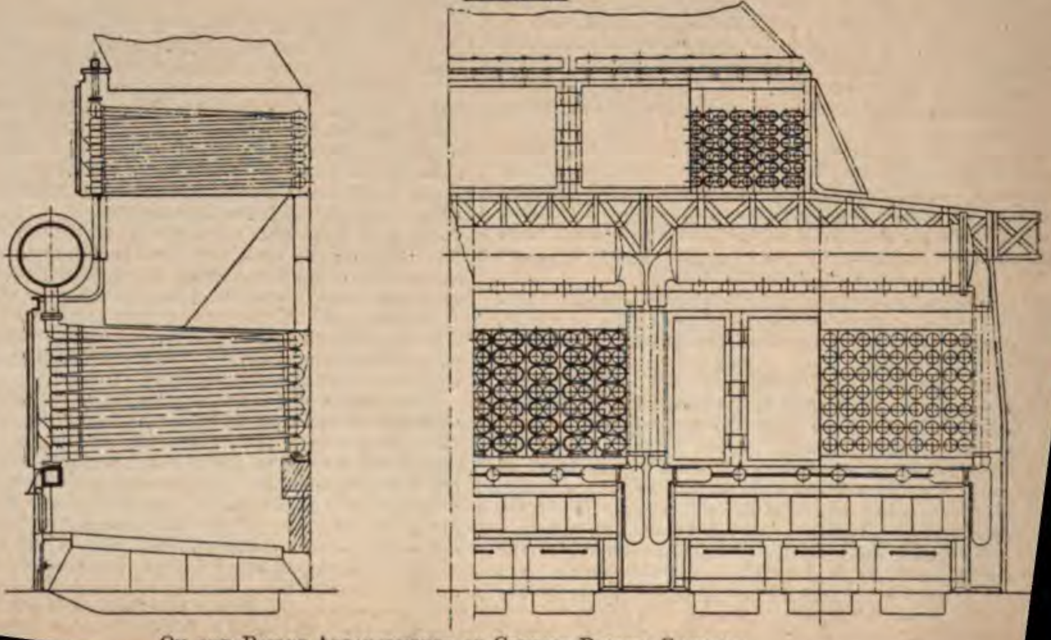
ANDROMEDA

FIGURE 5



HERMES.

FIGURE 6.



ON THE BOILER ARRANGEMENTS OF CERTAIN RECENT CRUISERS.

air pressure of, say, 2 in. (the maximum employed on the *Don Carlos* trials), as long as the coal lasts.

Working under these conditions is, however, very severe on the *personnel* of the stokeholds, and the endurance of the men would probably be found to be the measure of the time during which this power could be maintained.

In the case of the cylindrical boilers, a four hours' run is probably as long as these boilers could be worked at the maximum forced draught power.

These boilers have a tendency to suffer in the flame-box seams when long firebars are used, and it is only by the use of these long bars that the high powers looked for can be obtained. The tube ends also get choked up, especially if fitted with ferrules, and without ferrules the tubes have a great tendency to leak. It is probable that at the end of four hours the boiler efficiency would be seriously affected, and the power could no longer be maintained. On the other hand, however, the high speed obtained during these four hours might mean the salvation of the ship, and it is unfair to overlook this advantage.

It should be understood that the above remarks do not apply to forced draught applied to cylindrical boilers with moderate length of firebar, say 5 ft. 6 in., and with a heating surface of 2¼ ft. per I.H.P. Such boilers can be worked at about 17 I.H.P. per square foot of grate continuously at sea; but their size and weight would preclude their use in the type of vessel considered, as the power obtained would only correspond approximately to the results obtained in the ½ in. air-pressure trials of warships.

Raising Steam.

The rapidity with which steam can be raised, and the ready response to sudden demands in variation of power, are two matters of utmost importance in war vessels, and in both of these the water-tube types show a marked superiority over the cylindrical boiler. The large quantity of water contained in the latter makes it a question of hours to raise steam; and, if this operation is hurried, the boilers are strained to a serious extent, causing leakage. The same course of reasoning applies, though to a less degree, to any sudden and rapid large variation of power.

As to the two water-tube types, in both cases steam can be raised to full pressure in about 30 minutes from lighting fires. In the matter of variation of power there is also little to choose between them; for, although the large grate area of the Belleville type is an advantage, the safety with which the Yarrow type may be suddenly forced compensates for it.

Liability to Derangement in Working.

In this respect, apart from the difficulties mentioned under extreme forcing, the cylindrical type is to be preferred. All the arrangements, both of the boiler itself and of its accessories, such as the feed and steam pipe systems, are simpler than in the water-tube types. The boilers are fewer in number, thus reducing the number of pipes and connections, and the consequent liability to leaky joints, &c. The feeding is also less critical, owing to the large water level.

In addition to this, the introduction of salt water, even in considerable quantities, owing to leaky condensers or other causes, has little appreciable effect upon the working of the boilers.

Although, to obtain maximum results, these boilers must be in a state of thorough repair and cleanliness, they are still serviceable after considerable neglect such as would render any water-tube type quite useless.

With regard to the Belleville boiler, a grave objection, in the writer's opinion, is the enormous mass of mechanical detail in connection with it. Thousands of joints, all dependent upon extreme accuracy of workmanship, and many of them subject to extreme strain, due to varying temperature, are a pronounced feature in the design of this type

These points have been well met in the methods of manufacture, but most rigid supervision is required to maintain the accuracy necessary.

The feeding is also extremely delicate, owing to the small quantity of water contained, and the variable weight of this water at different rates of evaporation. This latter condition necessitates the introduction of the hot-well pumps and large feed tanks already described. The feed regulator employed, which certainly works admirably, is nevertheless a delicate mechanism, and has to be kept in a high state of efficiency. The number of boilers is also great for the power developed. This large subdivision has the advantage of involving only a small reduction of power, should one boiler become inoperative for any reason; but it certainly causes an enormous addition of important detail, such as feed-pipe and steam-pipe arrangements, all requiring care and attention. The furnace air pumping engines are also an additional complication, involving many extra fittings.

Whether these objections are valid extended experience alone can show, and it is an unquestionable fact that the vessels fitted with these boilers, especially since the addition of economisers, have passed through most severe trials with consistent success.

Referring to the Yarrow type, the construction in this case is extremely simple. None of the riveted seams are in direct contact with the fire, and the strains due to changes of temperature are not severe on the parts of the boiler under pressure, especially if the outer rows of tubes are curved.

The casings are probably the most severely tried part of the boilers, but no trouble need be feared from these, if carefully designed.

The great question about this and other small-tube types is the life of the tubes, owing to their comparative thinness. Any information which any gentlemen could give us on this point would be of extreme interest.

The tubes of the *Don Carlos*, as before stated, are ·128 and ·104 in thickness for the 1⅜ in. and 1⅛ in. tubes respectively. They are galvanised externally only, as is usual for this class of boiler in H.M. Navy. Mr. Yarrow, on the other hand, invariably galvanises the tubes both internally and externally, but this does not appear to be necessary in the case of a boiler with drowned tubes. It is probable that one cause of wastage on the outside of the tubes is the method of steam cleaning usually adopted in these boilers. This steam jet leaves the tubes damp, which naturally aggravates any tendency to rust.

In the *Don Carlos* the tube-sweeping arrangement was taken from the compressed-air pipes used in connection with the armament. This gives a perfectly dry air jet at high pressure, and proved a most efficient cleaner without the above objectionable feature. The feed system already described has the disadvantage of a large number of pumps, but in all other respects is very simple, and unlikely to become deranged. The area of water level also is large relatively to the quantity of water in the boiler, and this area is naturally the measure of the difficulty of steady feeding.

As to the possibility of working with salt water as make-up feed, our experience has certainly been against it in both the water-tube boilers considered. A serious tendency to prime, except at very low powers, is produced by even a small admixture of sea water, and anything approaching continuous use would be, in the writer's opinion, most undesirable. This is evidently borne out by experience, as the British Admiralty have recently taken special precautions in all their vessels to minimise the risk of salt water entering the boilers through inadvertence, or without the special knowledge of the officers in charge.

Facility for Overhaul.

In this respect the Belleville type has a great advantage, viz., the readiness with which complete elements can be taken from the boiler, repaired in the stokehold, and replaced. The other parts of the boiler are also of small dimensions, and, in case of a serious accident, the whole boilers can be taken out of the ship through the usual air casings without disturbing decks, &c., and with very slight derangement of even the minor fittings. The examination of the inside of the tubes, however, involves breaking and remaking a large number of joints.

As to the Yarrow type, the operation of renewing a tube is by no means difficult, although, if the defective tube is in the middle of a nest, all the tubes between it and the outer edge of the tube plate must also be removed. The method adopted is to work the tubes from hole to hole alternately between the two tube plates until the outer edge is reached. If, however, time is of importance, the tube ends can be plugged and steam raised again rapidly without any injury to the structure.

The inside of the tubes can be readily seen through and cleaned, owing to their being straight. This examination is merely a question of minutes, and thus is likely to be more frequently made than if considerable time and trouble were needed. It also involves the breaking of no joints, except the manhole doors. The outsides of the tubes are certainly not easily examined, and it is wise from time to time to remove a tube here and there to judge of the condition of

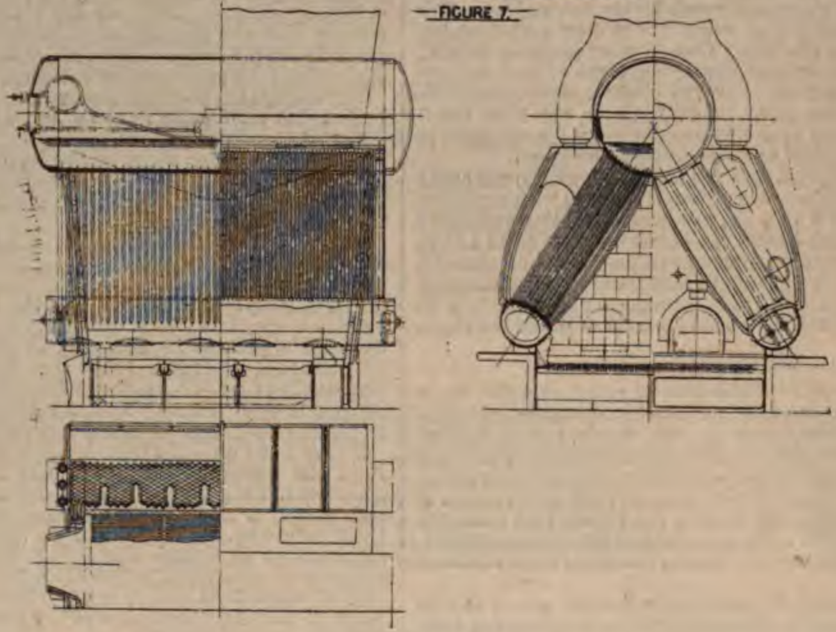
In the case of a serious accident, or seri
tating the retubing of a large p

would doubtless be slow. It is not a contingency likely to arise and in any boiler would necessarily be a dockyard repair.

Referring to the cylindrical boiler, the capabilities of this type for ordinary examination and overhaul are well known. For heavy repairs, however, such as renewing a furnace or flame box, the process is both tedious and costly, and in the extreme case of removing a boiler from the ship the whole of the protective deck and superstructure in way of the boilers has to be removed

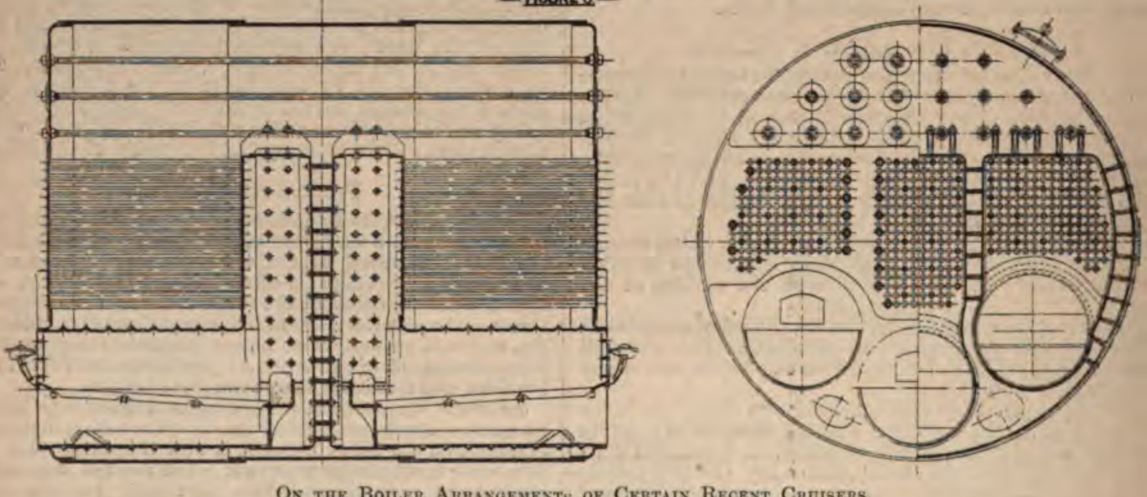
DON CARLOS I.

—FIGURE 7.—



"HAI CHI."

—FIGURE 8.—



On the Boiler Arrangements of Certain Recent Cruisers.

Steam Pressure.

With the water-tube types, the pressure of 300 lbs. per square inch is now customary. Such pressures are not practicable, except with water-tube boilers, without enormous increase of boiler weight, and have the advantage of enabling smaller engines to develop the necessary powers, with the attendant advantage of relative economy at low powers.

In cylindrical boilers the best balance of weight, power, and space economy appears to be obtained by using about 155 lbs. steam pressure. The additional economy in the engines, by using such higher pressures as are possible with these boilers, is not sufficient to justify the additional weight of boiler due to such higher pressures in vessels in which coal consumption is to some extent of secondary importance.

General Conclusions.

The above comparisons appear to lead to the following general conclusions in the case of the three types of boiler considered, starting on the basis of equal space occupied.

The Belleville type is well adapted for maintaining high continuous sea speeds for long periods, and is very economical at high powers. It is comparatively light, and well arranged for cleaning and overhaul. Steam can be raised quickly, and large variations in power made readily. It cannot, however, be forced, and has also the objection of great complication of detail and accessories, with consequent liability to derangement.

The Yarrow type is hardly so well adapted for continuous steaming at relatively high powers, and is not so economical* under such circumstances. It can, however, be forced to almost any extent with safety, and much higher speeds obtained for considerable periods. Steam can be raised quickly, and

---

*** More recent Yarrow boilers, fitted with Mr. Yarrow's feed-heating arrangement, are fully equal to the Belleville type in economy.**

large variations in power made readily. It is extremely light, and, being simple in detail, has small liability to derangement. Cleaning and overhaul are fairly easy, but the examination of the outside of the tubes is difficult.

The cylindrical type is about equal to the Yarrow for continuous high-power steaming, though probably slightly less economical. At low powers, however, it is very economical. It can be moderately forced with safety, and is well adapted for ordinary cleaning and overhaul. All its arrangements are extremely simple, and unlikely to become deranged. Sea water can be used in it with safety. It is, however, heavy; steam can only be raised very slowly, and large variations in power cannot be made quickly.

The above conclusions, the writer submits, point to the fact that the boiler question is one which must be dealt with in its relation not only to each individual class of ships, but to each individual service. The adoption of any type will depend upon what particular qualities are most desirable for the boilers to possess to meet the special work which the vessel is designed to do. The general naval policy of any Power will thus have a direct bearing upon the question of what type of boiler is preferable for a given ship.

In conclusion, it may be added that the three types considered are given merely as a comparison of actual examples of typical boilers, and are not put forward in any spirit of comparison with other types of boilers or other systems of working.

The writer wishes to take this opportunity of thanking Sir William White, K.C.B., Sir John Durston, K.C.B., and Colonel Watts for their kindness in allowing him to make public the facts contained in this paper.

Board of Trade Examination.—At the recent Board of Trade examination for extra first-class engineers, two of the successful candidates, Messrs. Charles Agate and Louis J. Leblique, were students at Leask's Marine Academy.

INSTITUTION OF NAVAL ARCHITECTS.

THE summer meeting of the Institution of Naval Architects was opened on July 18th in the Town Hall, at Newcastle-on-Tyne, at 10.30 a.m. The President of the institution (the Earl of Hopetoun, G.C.M.G.) and the members of the council met the members of the Reception Committee, headed by the Mayor of Newcastle (Mr. George Harkus), in the Council Chamber, and were conducted to the platform of the Town Hall, in which a large company, including many ladies, had assembled. At the commencement of the meeting the chair was occupied by the Mayor, who was supported on his immediate right by the Earl of Hopetoun, and amongst those present were:—The Earl of Ravensworth (past president of the institution), Sir W. H. White (Director of Naval Construction), Sir John Durston, Sir Edward J. Reed, Mr. F. K. Barnes, Mr. James Dunn, Dr. Francis Elgar, Mr. J. I. Thornycroft, Mr. A. F. Yarrow, Mr. S. W. Barnaby, Professor J. H. Biles, Sir Raylton Dixon, Sir Andrew Noble, Mr. W. T. Doxford, M.P., Mr. D. J. Dunlop, Mr. J. M'Farlane Gray, Mr. James Hamilton, Mr. John Scott, Mr. Philip Watts, Mr. Henry H. West, Mr. John Corry, Mr. James Riley, Mr. G. B. Hunter, Mr. Robert Thompson, Herr F. Laeisz, Sir Benjamin Browne (President of the North-East Coast Institution of Engineers and Shipbuilders), Admiral Cleveland, Colonel H. F. Swan, Mr. J. Duckitt, Admiral Carr, Captain Coerper (German Naval Attaché), Mr. John Gravell, Mr. T. V. S. Angier, Herr Otto Schlick, Mr. H. A. B. Cole, Mr. E. T. Agius, &c., with Mr. George Holmes, the secretary to the institution.

The Mayor of Newcastle, in welcoming the institution to the city, said: My Lords and Gentlemen,—I cannot conceive a more appropriate place than this old town on the banks of the Tyne for a meeting of members of the Institution of Naval Architects. The Tyne has been the scene of the wonderful progress made in the past half century in the designing and building of craft of all kinds, from the slender skiff used by the noted oarsmen of the north to the majestic leviathan launched a few weeks ago from the Elswick Yard for Japan—the England of the East. The Tyne is also the scene of the vast improvements made in marine engines, the latest type of which is to be seen in Mr. Parson's *Turbinia.* The programme arranged for you will enable you to see the great works of the North, commencing with the Elswick Works; and you will also have the opportunity of seeing the beauties of this city and of Northumberland. This city is indebted to Lord Armstrong for one of the most beautiful spots in the North of England—I mean Jesmond Dene. There is beauty everywhere you go, in every step you tread. The Mayoress and myself hope to have the pleasure of receiving you in Jesmond Dene this afternoon, and I am sure a sight of the beauties of the Dene will enable you to carry away a pleasanter picture of this old town than would be the case if your visit were confined to its great workshops. On behalf of all the citizens, and more especially on behalf of my colleagues in the Corporation, I offer you a most hearty welcome to Newcastle.

The President (the Earl of Hopetoun, G.C.M.G.), in reply, said: Mr. Mayor, and Gentlemen of the Reception Committee,—In the name of the Institution of Naval Architects, I desire to thank you most warmly for the kind words of welcome which your worship has just spoken, and for the spirit of hospitality which has led you to prepare the splendid programme which I see before me for our entertainment and instruction. Gentlemen, we who are members of the Institution of Naval Architects are no strangers to Tyneside hospitality. We have had previous experience of your goodwill towards us; for, twelve years ago, we held one of our most successful summer meetings in this city and in Sunderland. Those of us who had the good fortune to be present at that meeting can never forget the kind treatment which they then experienced at your hands. They have evidently spread the fame of their reception abroad; for, when it became known that the council had accepted another invitation to visit the Tyne and the Wear, an unprecedented number of applications was received from our members to attend the meetings. I only trust that the eagerness with which the institution has availed itself of your kindly intentions towards us has not put too great a strain upon the indulgence of the Reception Committee. During the period which has elapsed since our last visit, neither the industry of your port nor the prosperity of our institution has stood still. Both have increased by leaps and bounds, and we meet again after a twelve years' interval, neither being the worse for wear. Though your port is one of the oldest in the kingdom, though you supplied 27 ships to King Edward the Third's Navy five and half centuries ago; though you have been exporting coal by sea for more than six centuries, nevertheless you show no signs of having yet reached the limits of your growth. Within the lifetime of the present generation you have by your energy so improved your river as to render it available for all the purposes of modern commerce and of shipbuilding on the largest scale. Your yards and engineering works are being continuously increased in size and perfected in equipment. If I consider the products of these works and yards I cannot fail to be struck by the many important changes and developments which have taken place even during the short interval which has elapsed since the date of our last visit. The types of battleships and cruisers, the offensive power of naval artillery, the defensive power of armour, the size and types of merchant steamers, the means of generating and utilising steam, and even the machinery of production, all show the most remarkable advances. I will not allude in greater detail to these matters, because we are to be favoured with papers on many of them by such authorities as Sir Andrew Noble, Mr. Yarrow, Mr. P. Watts, Mr. F. J. Marshall, and Mr. G. B. Hunter, to whom our best thanks are due for doing so much for our professional instruction. I cannot, however, help looking ahead, and wondering if the next dozen years will bring us equally great changes; nor can I withhold my sympathy from my friend, the First Lord of the Admiralty, who has, in the interests of the British taxpayers, publicly expressed the hope that the great army of inventors would have mercy on the administrators, and not push them too hard. It gives me great pleasure, whilst congratulating you on the marked evidence of progress to which I have just alluded, to report to you that the institution over which I have the honour to preside, has also made rapid strides forward since last we met in this city. The numbers of our members have greatly increased. We have visited many British ports in the last few years, and we have even gone beyond our own islands, and have been received with the utmost good feeling by our fellow members in France and Germany, and by the Governments of those great countries. I mention these matters because we attribute no small share of our present activity and prosperity to the policy which we have adopted of visiting our colleagues at the great shipbuilding and mercantile ports. In this way we gain many sympathetic friends and supporters, to whom the institution would be a mere name if it remained always in London, and we enable many of our members, who could not otherwise do so, to participate directly in our work. Therefore, we feel that, in inviting us to visit you on the Tyne, you are contributing directly to our prosperity, and you are aiding us in a marked degree in carrying out the objects of our existence. Whilst on the subject of the institution I should like to say how rejoiced all we, your guests, are to learn of the growing prosperity and success of the North-East Coast Institution of Engineers and Shipbuilders, which has its seat in this city, but which does such excellent work all over the North-Eastern district. I have myself the honour to be an honorary member of that institution, and take the deepest interest in its success, an interest which is shared by all the members of the body which I represent. We both seek the same beneficent ends by the same methods. This constitutes in itself a bond of union between us; but we have, in addition, the associations of old friendship formed on the occasion of our former visit, and now happily to be renewed. We feel ourselves particularly fortunate in that Sir Benjamin Browne, who, as mayor of the city, received us with such open-handed hospitality in 1887, should this year be President of the North-East Coast Institution, and should in that capacity again take an active part in welcoming us here. Gentlemen, I cannot conclude without expressing my feelings on one other point. I am sure that every member of the Institution of Naval Architects who knew Lord Ravensworth in his capacity as its president, and who appreciated, as we all did, the great services which during 14 years he rendered to our society, will feel heartily rejoiced to see him once more amongst us as he is to-day, still active in serving our interests, still feeling the deepest sympathy with our work, and still, I am happy to say, looking hale and hearty. In the name of all of you, his old colleagues, I thank him for what he has done for us, and I wish him long years of health and happiness, and hope that he will continue to aid us from time to time by his presence and with his influence. There is one face familiar to most of you which we miss from amongst us to-day. I allude to our vice-president, Lord Armstrong, the founder of the great firm which is doing so much for our benefit, and who is prevented by his great age from playing the same prominent part which he did on the last occasion. But, though unable to be present, Lord Armstrong's thoughts are with us, and, as he cannot come to us, he has most kindly invited us to go and visit him in his beautiful home. I propose to send him, with your permission, the following telegram:—"The Institution of Naval Architects, assembled at its summer meeting at Newcastle-on-Tyne, sends its warmest wishes for the health and happiness of its vice-president, Lord Armstrong, and assures him that, though absent, he is not forgotten." Mr. Mayor, when we look down the list of the Reception Committee, and take note of the numerous and important interests which are there represented, and which have combined to do us honour, we cannot but feel flattered and grateful, and we draw the encouraging conclusion that you regard the work we are engaged on as being of the highest importance to the country and to your district.

Lord Hopetoun then assumed the chair as president of the institution.

Progress of Rifled Naval Artillery.

Sir Andrew Noble, K.C.B., read a lengthy paper on "The Rise and Progress of Rifled Naval Artillery." At the last meeting which the Institution of Naval Architects held in Newcastle a paper by Lord Armstrong and Mr. Vavasseur, on this question, was read and discussed; and, using that paper as a landmark, Sir Andrew Noble now gave a sketch of the subject during the 50 years of his connection with artillery, and noted the striking progress which artillery science, in common with other applied sciences, had made during the last years of the century now drawing to a close. In concluding his paper Sir Andrew said:—From the numerous experiments made, either by ourselves in this country, or by others elsewhere, I draw the following conclusions:—(1) To attack unarmoured structures, I have no doubt that shells charged with high explosives are a most formidable weapon. The large quantity of explosive that can be carried, and the power of immediately detonating the shell, permit the vessel to be attacked either by making large holes at or near the water-line, or if the shell should burst inboard the effect of the explosion and the destruction of everything in the wake of the shell would be very serious. (2) But with high explosives the shells are reduced to very small fragments, and even very thin steel plates resist penetration. Hence the importance of traverses, and supposing a first-class cruiser to engage two smaller cruisers firing high explosives, one on each broadside, a longitudinal traverse of very moderate thickness would be a protection, the importance of which could hardly be overrated. (3) Having regard to the size of the holes made by high explosives in unarmoured structures, I regard it of great importance that, wherever possible, the water-line should be protected from stem to stern with such armour as can be conveniently carried, and that the same protection should be afforded where the guns are carried on the main deck. On the upper-deck effective shields, and as thick as can be conveniently carried, should be attached to the mountings. (4) Where an attack is made against thin armour, shells charged with gunpowder are more effective than high explosive shells, as, dependent on circumstances, the former can be got to pass through thin armour and burst inside. I doubt if shells charged with any explosive can be got to pass through thick armour without bursting. (5) There is one serious objection to certain high explosives as bursting charges which is not shared by wet gun-cotton, and that is the liability to detonate if struck by another projectile, or even by a large fragment. Wet gun-cotton is quite safe in this respect, and yet, if fired, for example, by a fulminate, it detonates even more rapidly than in the dry state. This property has led certain Governments to adopt it as the high explosive for use on board ship. In concluding this paper, I desire to defend our Elswick practice, which I have sometimes heard attacked, of mounting as many guns on the broadside as can be conveniently carried. Personally, I share strongly the opinion which a distinguished admiral once made to me: that, supposing a fight between two cruisers equally ably commanded, the victory would remain with the ship that got in first her second broadside, and the victory would be more assured if the broadside were the more powerful. It must also be remembered that with our modern weapons allowance must be made for a gun or two being disabled without altogether crippling the broadside. For these reasons I prefer to carry as many guns as possible, even if the number of rounds carried per gun be reduced.

Sir **Edward Reed** characterised the paper as a wonderfully full record of the progress of war material in connection with the naval service. He regarded it as the very fullest and best record of work in connection with naval gunnery that they had ever had. The paper would be very valuable to him as one engaged in the practice of a profession most intimately connected with it. He discerned in the paper a disposition on Sir Andrew's part to open his mind and his hand more extensively than had ever been done before in that connection. No doubt the exceptional and paramount position of the Elswick Works was due to the circumstance that they had been constantly progressing in connection with ships and guns and gun mountings, and it was only natural and proper that a great firm, expending not only large sums of money, but the highest talent and the talent of many men in developing a business of that kind, should be somewhat reluctant to disclose the processes of their thought and of their action. Sir Edward went on to mention that, in 1863, when he went to the Admiralty, the guns of H.M. ships were moved about by exactly the same means by which a savage moved a log of wood at the beginning of the world. He succeeded in inducing the Admiralty to put a 12½-ton gun on board the *Bellerophon*—4¾-tons was the largest one previously. He also introduced mechanical means of working the guns, instead of the primitive method of "prising" it round with a hand-spike or stick.

Sir **William White** said that in the paper read they had the record made by the men who had done the work. The feature of the paper which most struck one who read it was the extremely modest way in which the great work was described. He was glad that Sir Andrew, in telling the story of the triumph of mechanical engineering as applied to naval armaments, had uttered a word of warning, and had said that, while mechanical appliances were a necessity, there should be no such extension of them as would attempt to turn the men into machines—into mere regulators of machines. It must be "the man behind the gun." In that the strength of the British Navy had always consisted, and always must largely consist. If the old resource and power of meeting emergencies were to be in any way destroyed by dependence upon mere machinery, that would be a matter which they must all regret. In the course of his duties it was not uncommon for him to attempt to introduce a limit to the extension of mechanical appliances. Sir Andrew had necessarily spoken most of the means of attack. Some of them had to consider not merely attack but defence, and there was nothing more difficult in watching the progress of invention than to know exactly where at any moment to strike the happy mean of developing the idea that offence was often the best means of defence, or of trusting to some extent to passive defence. The attack must always have greater flexibility than the defence, as Sir Andrew would agree. Those who were interested in the design of warships would be grateful to a man of the large experience and great ability of Sir Andrew Noble for putting before them, in that succinct, clear, and admirable form, his views on the problems of the present, and the prospects of the future.

On the motion of the **Chairman**, Sir Andrew was thanked for his paper.

Pressure on Dry Dock Blocks.

The "Fulda" Accident.

Dr. **Francis Elgar** read the next paper, and took as his subject "The Distribution of Pressure over the Bottom of a Ship in Dry Dock and over the Dock Blocks," which we refer to in our Editorial Notes.

The **Secretary** (Mr. Holmes) read a communication from the engineer to the Mersey Docks and Harbour Board, who said that it was by his advice that Dr. Elgar was consulted in the matter originally; and, after talking it over, they mutually arrived at the conclusion that the subject ought to be ventilated; and Dr. Elgar was the right man to do it, and the meeting of the institution presented a fitting opportunity. He congratulated Dr. Elgar on the fulness with which he had treated the matter, and trusted that the facts and figures laid before the meeting would be carefully studied by those who were responsible for the important process of dry-docking vessels. He was convinced that many vessels in the past had been dry-docked with a very small margin of safety; and it was very desirable that an operation so important should receive more than the general rule-of-thumb consideration which it appeared to have had hitherto.

Professor **Biles** stated that he had been one of the interested observers of the result of the *Fulda* accident, and of the legal inquiry which followed it. The question of the pressure which was brought on the forward block when the ship was docked with a large unsupported length was one which, at first sight, would seem to be very simple of solution. A common way of looking at that problem was to say that, if they had a ship which was a little overhung, and they gradually increased that overhang until the middle of the ship rested on the forward block, she was at a balance at that point, and consequently they might have the whole weight of the ship concentrated on what they might call the forward block. As they got less overhanging, they got the amount proportionately reduced, but still a very large proportion of the total weight of the ship—in the case of the *Fulda*, a ship weighing 6,600 tons. It would appear, in the first place, as if the pressure on the forward block might be something like from one-half to one-fourth of the weight of the ship, when one-fourth of the ship was overhanging. That method of considering the question was one based on the assumption that the blocks on which the ship rested were rigid blocks. If they assumed the ship to be slightly flexible, and the blocks to be rigid, undoubtedly a very large pressure would come upon the forward block. That pressure could be calculated, and, on that assumption, the pressure in the case of the *Fulda* would amount to something like from 1,000 to 1,200 tons, roughly speaking. If they assumed that the force was acting on the forward block, and that they then allowed the blocks to pass from the severely rigid condition to a perfectly elastic condition, then the forward block immediately sank down by the excessive weight put upon it, but that brought into play the elasticity of the next block, and so they got the support transmitted from the forward block right on. If they had 1,000 tons put on the forward block, and they had a ship supported for 300 ft. of her length, then they would have, roughly, about three tons per foot of length as the mean force that that unsupported overhanging would bring on the forward block.

Sir **Edward Reed** remarked that Mr. Lyster would make it an accepted fact that the forward blocks failed, first because of an excessive pressure on the foremost block. That was not by any means a foregone conclusion in his (Sir Edward's) own mind. The *Fulda* herself had been dry-docked several times on other blocks, with no evil results, and with the same overhang, of course. The impression created upon his mind was that the best evidence went to prove that the foremost block did not fail first. The blocks which first failed were abaft the middle of the vessel according to eye-witnesses. The vessel had a great, but not an excessive, overhang. With the investigations which had been put before them it stood to reason that the pressure forward must have been greater than the pressure aft. Dr. Elgar would say that, with such an overhang as that, the docking parties should have been notified of the great overhang, and there he was in agreement with the speaker who thought that everybody taking an exceptional ship like that would do well, and ought, to give notice of the exceptional overhang, so that the parties might provide such additional blocks as might be necessary. The blocks used for the *Fulda* were of cast-iron, very old, much worn, decayed, and originally of bad design. The improvement in the design of the blocks which had now replaced them tended to remove a weakness which the original blocks possessed. The first blocks were so weakened in the middle as to be very ill-adapted for the pressure of a bar-keel. Whatever might have been the cause of that failure, they would freely admit that it would have been better to have had notice given of the overhang. While it was undoubted that there must have been a heavy pressure on the foremost blocks, yet at the same time, as there was reason to think, the first failure did not occur there. It might have happened that the failure did not take place at all, in this case, from the pressure upon the foremost blocks, but from the original weakness of design, from great wear and tear, and that the *Fulda* cut through the blocks beneath her and fell to the bottom of the dock, because the blocks were not strong enough to sustain her.

Mr. L. Clark described a method he had devised for estimating the pressure of a ship on her keel-blocks under certain assumed conditions. As a result of his investigations, he had concluded that those docking ships should beware of cast-iron blocks; if the blocks had been all wood, the accident to the *Fulda* would not have happened.

Mr. H. H. West declared that the result of the inquiry respecting the *Fulda* accident had not altered his opinion one iota as to what exactly did happen. Mr. Lyster's memorandum mentioned the fact that the ship was damaged, and damaged excessively, at the fore end, and concluded from that that it was the fore end which went down first. He (the speaker) concluded that the vessel went down at the fore end last for two very good and sufficient reasons, amongst many others. There was one man, and one man only, who was found to have been in a position to make a competent observation of what happened, and neither the one side nor the other could find a second to him. Under closest cross-examination he did not give way one least bit from the story he told at first, and that was that he saw—after his attention had been called to the subject by the cracking noise some 14 or 15 minutes before the accident happened—whilst watching very carefully, the blocks fly out at the after end of the ship and then the vessel come down forward. The ship was most severely damaged at the fore end. He thought that they might conclude that the ship must inevitably have come down with the fore end last. If the vessel was resting heavily on the blocks about number 24, and this gave way first, numbers 24, 25, and 26 would gradually yield, one after the other, and bring into play 23, 22, 21 and 20, gradually crushing as the vessel went down into the dock. He, coming from Liverpool, should be the last to cast any aspersion upon the blocks which were used. He had his own opinion, but he was convinced that the lesson that had been learned from the *Fulda* would make it practically impossible for any such casualty to occur again, either in Liverpool or in any other place.

Professor Hele-Shaw gave a lengthy demonstration, with the aid of the blackboard and mechanical contrivances, of the causes of strain on docked vessels.

Dr. Elgar replied, and said that with reference to the manner in which the *Fulda* went down, he did not wish to argue that there. He might, however, have revealed his opinion in the course of his paper. His opinion was based upon this, that, upon any reasonable method of calculation, the more one saw of these stresses upon the foremost blocks, the more one was convinced that there was not the slightest doubt that the region of greatest pressure was in the neighbourhood of the foremost blocks. These blocks, which had been in use for something like 40 years, had never yet been objected to by anyone. The Board was now surprised to learn that these blocks were defective, and, wishful of light, wanted the opinions of the institution on the matter. An objection to that kind of block, as compared with blocks made of wood, was that the power of the blocks to distribute strain was limited.

The institution accorded a vote of thanks to the author of the paper.

Mr. Nelson Foley's paper on "A New Method of Forced Draught," taken as read, is referred to in our Editorial Notes.

This terminated the morning meeting.

In the afternoon the members of the institution and their ladies were entertained to a garden party in Jesmond Dene, their hosts being the Mayor and Mayoress of the city.

In the evening the dinner of the institution, held in the large hall of the Assembly Rooms, was largely attended, and most enjoyable.

The members reassembled in the morning of Wednesday, July 19th, in the hall of the Literary and Philosophical Society, for the reading and discussion of papers. The President (the Earl of Hopetoun) occupied the chair, and there was a large attendance.

At the commencement of the proceedings the meeting approved the election of 107 gentlemen as members, associate members, and associates; and

The President informed the meeting that this was a record number to be elected, a fact of which, he thought, the institution might feel very proud. Mr. Watts had been an excellent recruiting sergeant, and had brought quality to the institution as well as quantity, for he had induced a number of distinguished gentlemen to join the society.

Elswick Cruisers

Mr. Philip Watts, the chief of the shipbuilding department at Elswick, read a paper on "Elswick Cruisers," which we propose publishing in full in our next issue.

Admiral Sir Edward Freemantle stated that, during the war between China and Japan, he was very much struck with the manner in which the Japanese cruisers—Elswick-built—were worked. During the attacks on Wei-hai-Wei and Port Arthur, if the cruisers remained in port a few hours it was as much as they did. When the Chinese torpedo-boats tried to make a dash for Wei-hai-Wei, the flying squadron came out, headed by the Elswick cruisers. These vessels did the most cruising, and the most successful cruising, during the war. He was glad that Sir William White was present, for that gentleman would be able to explain how it was that the vessels of the *Terrible* class, which were so much larger, were, to put it plainly, less powerful. With regard to coal and ammunition supplies, he believed that not only should there be colliers attached to every fleet, but there should also be ammunition ships and hospital ships. He believed that, nowadays, they should look round the ships and see what they could dispense with, such as above-water torpedo-tubes, &c. The same remark applied to the four anchors and cables. When one asked the Admiralty to take one anchor away, the Admiralty replied, "Oh, no, that ship always had four anchors." But the new ships had only three. He wished they had some of the Elswick cruisers in the Royal Navy.

Professor Biles said that when they had a large organisation everybody connected with that organisation found some fault in, and wanted to improve, a ship, and necessarily when a new ship came to be built all the faults that had been found must be avoided, and all the improvements that had been suggested must be put into the new ship. With a large number of people, each having things in view, a great many things would get into the vessel which, if they were left to the judgment of a single man, would probably not be added. If some of the Admiralty ships were heavier than some of Mr. Watts's, it might be that that was owing to the desire of everyone connected with the service to have something added to these ships.

Sir Edward Reed said that this paper seemed to him to take rank with the paper of Sir Andrew Noble, and in a large measure to complete the record of the Elswick Works. As the Elswick Works were by far the most important concern in that district, and occupied a high position in the world, he thought that those present might congratulate themselves on coming to Newcastle, and on having been met by that great establishment with the presentation of papers of such importance. As he had been connected with several of the vessels mentioned in the paper, it would not be inappropriate for him to say a few words upon the important and delicate points on which the debate had touched. Admiral Freemantle, in the spirit of gallantry and courage which had always animated him, had gone straight to the point, and wanted to know how it happened that there was such a remarkable contrast between the Elswick cruisers and the Admiralty vessels. In so far as the *Esmeralda* and the *O'Higgins* were concerned, they, such as they were, had come about as follows:—It had been his duty, on behalf of the Chilian Government, which ordered these ships, in association with the Chilian admiral, to define fully the requirements of the Chilian service and to invite tenders and designs for the vessels. When these came in they were very closely examined, and the success of the Elswick Works in obtaining orders for these ships was entirely due to the merits of the designs judged by these considerations, which the owner of a cruiser would naturally bring into account. Mr Watts had been asked by Professor Biles to give fuller details of the weights. He would like to see whether they could not, before a future meeting of the Institution, get someone to exert his persuasiveness with Sir William White on the one hand, and with Mr. Watts on the other hand, and get them to freely disclose all their statements of weights, and to make them the subject of a special paper to be read before that institution. He thought that the Elswick designs owed much of their excellence to the fact that Mr. Watts had succeeded in making every necessary element of protection available for strength as a special matter of study, It was possible to design a ship, and then to begin to think about its protections and the things it had to carry. He was sure that the most lynx-eyed architect could not discover in the Elswick ships any wasted weights. These ships owed much of their merit to very great mastery with respect to their form. This very great excellence of form was accounted for by the able knowledge of the designer. He was not aware of any undue economies of weight in the Elswick designs. Sir William White had not the same freedom that Mr. Watts had in connection with the designing of ships. The Admiralty and many others had a voice in the design, not to mention Sir William's subordinates. He appealed to Sir William White and to Mr. Watts to contribute, perhaps jointly, a paper on a future occasion setting forth the real secrets in that matter, and explaining why the Elswick ships differed from the Admiralty ships. The most recent Admiralty ships were much nearer to the pretensions of the Elswick ships than any had ever been before. That might have been because of the letters which he had been writing to the *Times*, saying that something ought to be done. He sympathised with Sir William White in the fettered position in which he was placed.

Sir WILLIAM WHITE, on rising to continue the discussion, was loudly applauded. He said he would like, at the outset, to say how much he was touched by the deep sympathy of Sir Edward Reed. It would be a great misfortune if the proceedings of that Institute degenerated into a criticism of the professional capabilities of any of its members, or that it became a medium for discussing, on very imperfect information, Admiralty policy. His friend and successor at Elswick, Mr. Watts, whose appointment he was glad to say he had the honour of arranging when he returned to the Admiralty, and whose subsequent career had more than justified all the high hopes that he (the speaker) then had of his (Mr. Watts's) future, had read a very capable paper. It seemed to be forgotten that, before the speaker returned to the Admiralty, he had the honour of working with and for the Elswick Co. for some years, and contributed, in some degree at all events, to the formation of that great establishment. He might be supposed, therefore, to have a fairly full knowledge of Elswick methods as well as of those of the Admiralty. He had a full knowledge of the principles upon which the Elswick ships were designed, and he had full and the latest knowledge of Admiralty policy and of Admiralty methods. He wanted to express his sincere admiration of the professional skill which was shown in Mr. Watts's designs. Admiral Freemantle rejoiced in a newly acquired freedom. If the Admiral and other naval officers of eminence would devote their energies to helping those who had to design ships to carry out this economy of weight and equipment, the naval architects would be much obliged. Working at Elswick, in close touch with the engineers, they were working also in the closest touch with colleagues who had everything to do with ordnance, gun mountings, and the armaments of ships in every detail. Those who had not had that advantage hardly knew how much they missed. It had been his lot to have held up for his admiration and imitation, in the Admiralty, ships for the design of which he was responsible before he went to the Admiralty. The gain which Mr. Watts must have had in his professional work from his early association with the late Mr. Froude no one could know better than he (the speaker) did. He would like to remind the meeting, however, that he had behind him at the Admiralty the most perfectly equipped experimental establishment in the world. He took exception altogether to the suggestion that in the Admiralty one was at a disadvantage in the selection of form. Quite the contrary. Was it to be suggested that the Admiralty officers were in any way behind the times with regard to structures and materials of warships? He claimed that they were prepared to face comparison with the world. Propulsion was largely a matter in which they were dependent upon the marine engineers for skill, enterprise, and constant progress. Was there any justification for the suggestion that in Admiralty practice as regards marine engineering they were failing to advance? The charge that was most frequently made at present was that they were advancing too fast. As to the disposition of the weights which came into armament, equipment, and protection, there might be infinite opinions as to the form of the best distribution. They had heard from Admiral Freemantle of what he considered to be the insufficient armament for some of their ships. They might have quadrupled the number of guns in the *Powerful*, but would they have increased the fighting efficiency? If history was to be trusted, all naval actions had been determined by the slaughter of men or by the loss of *morale* and fighting power of the men on board the beaten ships. Whilst active offence was a valuable quality it was important to consider the question of defence. They did not know how the disposable weights of the Elswick ships were disposed, and, if he were Mr. Watts, he would not tell them. As to speed, it was the commonest thing for him to see tabulated statements of speeds of ships which rested upon no common measure whatever, neither of the power developed, nor the condition of the ship at the time of trial, nor the duration of the trial, nor, in some cases, the means of testing the speeds. In steam trials of warships, "jockeying" was not yet extinct, but the Admiralty did not "jockey." He did not want them to think that he was applying these remarks to the Elswick steamers. If any one, accepting the conditions laid down for the design of any vessel belonging to the Royal Navy, for which design he, the speaker, was responsible, could show him how, taking the conditions at the time at which the ship was designed, he could produce a vessel superior to the design which was then accepted, he should be very glad indeed to see that demonstration. He was not infallible. He could only claim that he had not spared himself in the public service. If he had sought his comfort he should never have left the Elswick Works. Elswick was the place above all others where a man could work free from any limitations which must be enforced elsewhere. It had been his business to inform himself of the work of others, and he publicly acknowledged the enormous obligations under which he laboured to his professional brethren outside the Admiralty, and amongst these he included Mr. Watts.

Colonel WATTS replied. He mentioned that Professor Biles had referred to the question of strength and weights. He ventured to think that the weights had not been cut down beyond the proper limit. His firm did not propose to give their weights. Nor did they propose to give their specifications and drawings. They had given their results, which he was prepared to affirm were accurate. There was no "jockeying" about them.

BOILER ARRANGEMENTS IN CRUISERS.

Mr. F. T. MARSHALL read the next paper, "The Boiler Arrangements of Certain Recent Cruisers," which we publish in full in this issue.

Sir JOHN DURSTON congratulated the author—the son of an old friend of the members, Mr. Frank Marshall—on the very fair manner in which he had drawn up his paper.

Mr. YARROW thought that Mr. Marshall had dealt very fairly with the merits and objectionable features of the different types of boilers. The paper was particularly valuable at the present time, because everyone was interested in water-tube boilers and were all ready to grasp at any information that they could get upon the subject. His firm attached great importance to the bell-mouthing of the tubes. The bell-mouthing was the last opportunity that they had of testing the ductility of the tubes. At the last operation of bell-mouthing, some few of the tubes would be found to split, and it gave them the last opportunity of discarding the faulty ones. Mr. Marshall had said that any information which anyone could give which would tend to increase the durability of the tubes, on account of their comparative thinness, would be welcome. As that was the subject which he (the speaker) proposed to deal with at the present meeting, he would not touch upon it then. Mr. Marshall had said that it was the practice of the speaker's firm to galvanise the tubes internally and externally. All his firm now did, however, was to galvanise six or eight inches of the lower ends of the tubes. They did not attach so much importance to galvanising the tubes as they had done formerly. Although the boilers in the *Don Carlos* were the largest installation of that type that had been made—and, he thought, the only installation that Messrs. Armstrong had made in this country—still, those boilers had been used by foreign Governments to a large extent. In the Dutch Navy five years ago three cruisers were designed and these boilers were adopted. These vessels passed through their trials very well, and had been in commission for some time, with highly satisfactory results. The Austrian Government recently adopted these boilers in one of their cruisers, and were so highly pleased with them that they telegraphed to his firm congratulating them on the success of the boilers. The installation of the Portuguese cruiser must not be looked upon as standing alone, therefore.

Ice Breakers.

Mr. H. F. Swan read a paper on "Ice Breakers." He said: There can be no doubt that the employment of ice-breakers is destined to become a very important factor in connection with steam navigation generally, and that many ports which formerly were partially, and others entirely, closed during the whole of the winter, will become available for commerce all the year round. It would be impossible, in the limits of a paper of this description, to give many details as regards the construction of such vessels. It will, however, be interesting to the members if I give a few particulars of two vessels built last year, embodying all the latest practice, and which have been at work during the past winter with eminent success. These vessels were the *Sampo*, of 2,000 tons displacement and 3,000 I.H.P., built for the Finnish Government, and the *Ermack*, of 8,000 tons displacement and 10,000 I.H.P., built for the Imperial Russian Government. The *Sampo* has one single propeller aft and another one forward, and her chief dimensions are:—Length, 202 ft.; beam, 43 ft.; depth to upper deck, 29 ft. 5 in. Her bow and stern have considerable overhang, the contour being such as to strike the ice at a very acute angle, so that when the vessel is driven with considerable force, she has a tendency to rise on the ice in a slanting position, which, whilst it conduces to bringing her maximum weight to bear, does so in a manner which mitigates the blow to the vessel herself. The *Ermack* marks an immense stride in the construction of ice-breakers, being fully three times as powerful as any vessel previously constructed; moreover, she has four propellers, three placed aft and one forward. Her principal dimensions are:—Length over all, 305 ft.; beam, 71 ft.; depth to upper deck, 42 ft. 6 in.; the contour of her bow and stern also shows a quite exceptional amount of overhang, and both she and the *Sampo* had their sides inclined outwards at a considerable angle from the vertical, to lessen the strain when the vessels are being nipped in the ice floes. The whole construction of the vessel is exceedingly strong, and she is subdivided into 48 compartments, the water-tightness of which has been tested in the most efficient manner, and, as an example, it may be mentioned that after the vessel was launched, and her engines and boilers fitted on board and all complete, one of the boiler rooms was filled with water to the upper deck, the bulkheads practically showing no deflection. This is probably the most severe test to which the bulkheads of any ship have ever been previously subjected, and as the other parts of the hull are relatively as strong, this gives a good indication of the vessel's solidity. The frames are placed 12 in. apart, and the thickness of the ice belt varies from 1¼ in. at the ends, where most of the ice-breaking is to be done, and is slightly reduced in other parts less exposed to shocks when breaking ice. In ice-breakers generally, it is highly important to have the model of a rounded form, and to have the outside surfaces as smooth as possible, both seams and butts for this reason being flush-plated. It is desirable, also, that the vessels relatively should be short and broad, as this is found to greatly assist their manœuvring in ice, and prevents the broken pieces from clinging to the shell plating. It is also important to have the pumps of enormous power, connected with trimming tanks at the bow and stern, and also at the sides of the ship, so that if the vessel gets caught in the ice, her horizontal plane may be varied in any sense desired, whereby she can the more readily release herself. Experience with the *Sampo* and *Ermack* has shown that pack ice of practically any thickness can be negotiated; and in the case of the latter vessel, she on one occasion encountered a pack which was measured and found to be of a total thickness of 34 ft., 9 ft. being above the level of the field, and through which she successfully forced her way, a feat which would have been quite impossible but for the action of the forward propeller. As regards the propellers themselves, I may mention that we have made them both of bronze and of nickel steel, and have not so far had a broken blade, and this in spite of the fact that on many occasions the engines have brought up "all standing," which, I need hardly say, requires their being designed in all their working parts, both as regards scantlings and surfaces, on a basis greatly in excess of what is usual in machinery for ordinary purposes. Experience with the *Ermack* has shown that she has broken composed ice of 8 ft. 3 in. in thickness, and she has gone through field ice of about 40 in., with 6 in. of snow upon it, at a speed of 2½ to 3 knots; moreover, she has been driven at a speed of about 10 knots through clear ice of 24 in., whilst ice under 18 in. has little effect upon her. It is found that snow has a wonderfully great retarding influence upon an ice-breaker, much more so than a similar thickness of solid ice. Her manœuvring powers are remarkable, seeing that with her helm only, she can turn in a circle of only twice her own length, and her handiness was specially shown when she entered the frozen-up port of Cronstadt on March 16th last, proceeding without stopping through an entrance only 95 ft. wide, and berthing herself alongside the quay without assistance, whereas under ordinary circumstances of navigation in open water, steamers are in the habit of invariably being assisted by tug boats. Her practical utility was not long in being put to the test. Immediately on her arrival, urgent word was received from Revel that a number of steamers were in great jeopardy; she at once proceeded there, and was the means of liberating 33 steamers, of an aggregate value of a million and a-half sterling. She subsequently returned to Cronstadt and St. Petersburg, and was instrumental in relieving and facilitating the entry of some 40 more steamers, several weeks earlier than if they had waited the ordinary opening of the navigation. The above performance is a very conclusive proof of the commercial value of such a vessel. When a passage has once been broken, vessels of ordinary construction can usually follow in the channel thus made without suffering injury; where, however, vessels are intended to work regularly in this way, it would be advisable to give them a little additional strengthening, especially as regards the bow, and as regards the propeller, this had better be of steel somewhat stronger than ordinary practice. It is necessary here to point out that all the foregoing remarks apply to ice-breaking in the Baltic, or where the ice is formed gradually at moderate temperatures, and that the same result could not be looked for in the case of service in the Arctic regions, where the ice is of a much harder and more brittle description, and it probably would not be prudent to have the bow propeller shipped when a vessel is employed among the heavy ice of the Polar Seas. A very important application of ice-breaking steamers is shown in their ability to form connecting links in railway systems in crossing large stretches of water (which it would be either impossible, or too costly to bridge). In conclusion, I can only reiterate my belief that the employment of ice-breaking vessels has not yet reached anything like the importance that it will yet achieve, and that still more important developments in this class of vessel may be expected in the future.

Admiral Makaroff, who was invited by the President to speak on this paper, said the problem which was laid before the shipbuilders with regard to this ice-breaker was very difficult. A ship was wanted which would be able to go into the Neva River, drawing 18 ft. 6 in. That ship was to break the ice in the Baltic during the winter. It was to be used in the same kind of occupation in more northern regions in the summer. The difficulty, however, was not the thing before which the English engineers stopped. There was no ice to break the heart of the English engineer. They found out the way to surmount all these difficulties, and the ship was found to be a success. He was in charge of the trials. They never asked what sort of ice was before them. They asked where the ice was, and then they charged it. The ship had sometimes to go as fast as 15 knots and charge the ice. He wished to draw their attention to the vessel's bulkheads. Bulkheads ought to be really water-tight, and not *soi-disant* water-tight bulkheads. If it happened sometimes that they were not water-tight, he would be very glad to say that it was not the fault of the shipbuilders. They were never asked to build bulkheads which would stand such a pressure. They were asked to build a cheap ship, and the one whose tender was lowest usually got the contract. If, from time to time, ships went to the bottom owing to the bulkheads being imperfect, it was not the shipbuilder's fault exactly, but it was somebody's fault. The other feature in this vessel which he wished to draw attention to was the buffer, which was designed to minimise the force of collision between the *Ermack* and any other steamer. As to whether it was possible to break up the Polar ice, the Baltic ice was from 2 ft. 6 in. to 3 ft. thick. The first ice they encountered in their Polar trial was 7 ft. thick. In the very near future, they hoped to show to what extent it was possible to break through the ice on the way to the North Pole.

Visit to Elswick.

At two o'clock a large party were entertained at luncheon by the Chairman and Directors of Sir W. G. Armstrong, Whitworth & Co., Limited, in the mculd loft.

After lunch, visitors passed to the joiners' shop, where various wood-working machines were seen. A door and stairway on the right lead down across the railway lines to the jetty, off which lies the battleship *Hatsuse*, recently launched for the Japanese Government. Principal dimensions: — Length, 400 ft.; breadth, 76 ft. 6 in.; depth, 43 ft. 11 in.. draught, 27 ft.; displacement, 15,000 tons; I.H.P., 14,500 tons; speed, 18 knots; coal supply, full, 1,690 tons. Armament:—Four 12-in. breech-loading guns; 14 6-in. quick-firing guns; 20 12-pounder quick-firing guns; eight 3-pounder quick-firing guns; four 2½-pounder quick-firing guns; five torpedo-tubes. Armour:—Belt, full length, from 9 in. to 4 in. thick; citadel, 250 ft. in length; 6 in. thick; barbettes, 14 in.; casemates, fronts, 6 in.; casemates, backs, 2 in.; conning tower, 14 in. in thickness.

Visitors then passed under the 100-ton hydraulic sheer legs. On the landward side are the blacksmiths' shop and fitting shop, and alongside the jetty lie two destroyers. Principal dimensions:—Length, 220 ft.; breadth, 20 ft. 6 in.; depth, 13 ft. 6 in.; draught, 5 ft. 6 in.; coal, normal, 45 tons; coal, full, 90 tons. Armament:—Two 18 in. torpedoes; one 12-pounder quick-firing gun; five 6-pounder quick-firing guns; two Maxim quick-firing guns.

The near one—a 30-knot destroyer—is engined by the Wallsend Slipway Co. She was recently launched, and has already begun her trials. The further destroyer, engined by the Parson Marine Steam Turbine Co., with Mr. Parson's well-known turbine motors, is expected to reach a speed of 35 knots.

Moored in the river is the protected cruiser *Fourth of July*. Principal dimensions:—Length, 360 ft.; breadth, 46 ft. 6 in.; draught, mean, 17 ft.; displacement in tons, 4,160. Armament: — Two 8-in quick-firing guns; 10 4·7-in. quick-firing guns; 16 3-pounder quick-firing guns; six 1-pounder quick-firing guns; and five torpedo-tubes.

Visitors then passed along at the head of the building slips.

The first two berths are occupied by Norwegian battleships of great offensive and defensive power. Principal dimensions:—Length, 290 ft.; breadth, 50 ft. 6 in.; depth, 27 ft.; draught, 16 ft. 6 in.; displacement, 3,850 tons; speed, 16 knots; coal supply, normal, 250 tons. Armament:—Two 8·24-in. quick-firing guns, in gunhouses; four 6-in. quick-firing guns, in casemates; two 6-in. quick-firing behind shields; eight 12-pounder; six 3-pounder; two submerged torpedo-tubes; armour belt 6-in. Krupped steel.

Beyond these vessels, and lying off the jetty, is the United States cruiser, *Albany*. Principal dimensions: — Length, 330 ft.; breadth, 43 ft. 9 in.; draught, 16 ft. 10 in.; displacement in tons, about 3.450. Armament:—Six 6-in. quick-firing guns; four 4.7 in. quick-firing guns; 10 6-pounder quick-firing guns; four 1-pounder quick-firing guns; four Maxim guns; two 12-pounder field guns.

Passing round the furnaces, visitors reached the three armour-clad berths, from the first of which the *Hatsuse* had just been launched. On the two adjoining berths lie two Japanese armoured cruisers of the *Asama* type. Principal dimensions:—Length, 400 ft.; breadth, 68 ft. 6 in.; draught, 24 ft. 3 in.; displacement in tons, about 9,800. Armament:—Four 8-in. breech-loading guns, in two barbettes; 14 6-in. quick-firing guns (10 in casemates); 12 12-pounder quick-firing guns; seven 2½-pounder quick-firing guns; four torpedo-tubes, submerged. Armour:—Armour belt, 7 in. and 3½ in.; armour citadel, 5 in.

Steel Works.

Siemens melting furnaces, capable of casting 800 to 1,000 tons per week. Hydraulic forging presses shown at work, the process of casting steel ingots was shown.

Ordnance Department.

The shops in the Ordnance department were taken in the following order:—

No. 18 Shop: Finishing and finished guns, of 12-in., 6 in., and 4·7-in. calibre, and smaller sizes.

Two 6-in. quick-firing guns, mounted on an upper deck carriage and a between deck carriage were shown.

These guns show respectively the system of quick-firing inaugurated by Sir W. G. Armstrong, Whitworth & Co., Limited, in 1887, and one introduced by them in 1893. In the first system the charge is contained in a metal cartridge case fitted with a primer. After the projectile has been inserted into the chamber the cartridge is entered and pushes home the projectile, and thus allows the breech to be closed; the gun is then ready for firing. In the second system the gun is fitted with a modified de Bange obturator, the charge being contained in a silk cloth bag. The projectile is rammed home and the charge inserted. A primer having been inserted in the vent axial, the breech is closed.

In both systems a single movement of a hand lever opens or closes the gun, and in neither case can the gun be fired until the breech is actually closed and locked.

The mountings also show two types. One with a large shield is intended for guns placed in exposed positions on the upper deck of a ship, or for coast defence. The other has a small circular shield, and is intended for guns placed in casemates or between decks.

One man easily trains or elevates the gun and fires when his sights are properly aligned, and four men are sufficient to fight the guns. This is, of course, not counting magazine numbers.

The rapidity of fire with these guns is from eight to nine rounds per minute.

No. 29 Shop: General gun carriage work, electric work, search lights.

The visitors passed to the scene of the recent fire. This fire, one of the largest that has ever occurred in Newcastle. was discovered at 3.10 on the morning of Sunday, June 10th. It was first noticed in a gallery of No. 6 shop,and, spreading with great rapidity, in the course of three hours almost completely destroyed three shops, Nos. 6, 7, and 33. Much has been done since the fire in the way of clearing out the debris and making preparations to rebuild and refit the shops.

No. 17 Shop: Submerged and above-water torpedo-tubes.

No. 28 Shop: Small quick-firing guns.

Over bridge into

No. 12 Shop: General hydraulic fittings for heavy gun mountings.

No. 11 Shop: Machine shop for guns. Turning, boring, and rifling machines.

Engine Works.

Bridge yard, south erecting shop, brass foundry, north erecting shop, brass rolling mill. Steam pumping engines, swing bridges, dock gates, and hydraulic machinery generally.

The firm of Sir W. G. Armstrong, Whitworth & Co., Limited, in addition to the works at Elswick, has branch establishments at Manchester and in Italy, and a second shipyard on the Tyne at Walker. The firm employs more than 25,000 men.

In the evening Sir Andrew and Lady Noble were "At Home" to members of the institution and their ladies at Jesmond Dene House.

The members reassembled on Thursday, July 20th, in the hall of the Literary and Philosophical Society, for the reading and discussion of papers. In the temporary absence of the Earl of Hopetoun, the president of the institution, the chair was occupied by Sir Edward J. Reed.

Nickel v Mild Steel Tubes for Water-Tube Boilers.

Mr. A. F. Yarrow read a paper descriptive of "Some Experiments having reference to the Durability of Water-Tube Boilers," which we publish in full in our present issue.

Sir John Durston, who opened the discussion on the subject, said they must highly appreciate the liberality with which Mr. Yarrow had put the results of his costly experiments at their disposal. It occurred to him that they should have gained a very considerable step in the construction of boilers, water-tube boilers especially, if they could obtain the tubes of a material which, when subjected to such actions as Mr. Yarrow had described, would not commence to deteriorate or oxidise until it had reached a much higher temperature than that at which mild steel would commence to deteriorate. Apparently deterioration of the mild steel and of the nickel steel commenced at about the same temperature, but the experiments carried out by the Admiralty fully confirmed those of Mr. Yarrow, in showing that the deterioration of nickel steel was much slower than that of mild steel. The nickel steel was strongly electro-negative to the mild steel. That action could be reduced by the usual application of zinc plates, and, probably, with experience, obviated. With regard to the variation of expansion of nickel steel and mild steel, that point could be easily met when the two rows of tubes nearest the fire were, as Mr. Marshall suggested, bent tubes. If they put the nickel tubes nearest the fire, the effects of the expansion would not be so serious. The fact of the contraction of the mild steel tubes might explain, in some degree, the tubes coming out of the tube-plates. It was gratifying to know that English firms were taking up the manufacture of nickel steel tubes.

Mr. Riley stated that 10 years ago he endeavoured to attract attention to nickel steel as an alloy, and at that time drew attention to that particular alloy—25 per cent. nickel—on every occasion when that material was being discussed in that institution. He must confess that he was surprised at one of the remarks in the paper that morning, to the effect that the ductility of the alloy might be taken to be almost that of mild steel. That was not at all in accordance with the facts as he had found them. The mechanical tests which he was able to make showed the ductility, as measured by extension, to be at least 50 per cent. more than that of the ordinary mild steel, strength largely above that of mild steel—he meant ultimate breaking strength—and an elastic limit superior to that of mild steel. Nickel steel lent itself more to deformations, such as flanging, drawing, bending, &c. Some two or three years ago, at the spring meeting of that institution, this matter was discussed. At that time the question of tubes came up, and he strongly recommended that attention should be given to that metal for tubes, as likely to remove or overcome a good many difficulties to be met with in mild steel. He was glad that more influential persons had now taken the matter up, and that attention was now to be paid to it.

Mr. Thornycroft thought the institution was very much indebted to Mr. Yarrow for laying before it the results of some experiments which were, at the present time, of great interest. It was well known that the water-tube boiler, which had come into extensive use, was in trouble because of the want of durability of tubes. The first experiment treated gave them an idea of the relative advantage of that alloy, which Mr. Riley brought before them so frequently and persistently, and which now, he hoped, must get the attention which it should have. He thought that the temperatures to which Mr. Yarrow subjected his specimens went beyond what they ought to expect in any well constructed boiler.

Another speaker mentioned that, some years ago, Messrs. Thornycroft sent a torpedo boat across to Denmark. The fresh water was expended simply through the frequency with which it was necessary to blow the fog whistle. The boilers were filled with salt water, but nothing went wrong as a result. On another occasion they sent a boat to South America, and for a long time nothing but salt water was filled into the boilers. Yet in neither case was there any corrosion or salt deposit.

Mr. Sampson remarked that there had been a comparative falling off in the nickel steel tubes when they were submitted to the superheated steam test. Nevertheless, in considering the adoption of tubes of that description, they must look at the matter from a broad standpoint. The superheated steam test represented a state of things which was altogether abnormal. They should look at the mere fact that the nickel steel tube did three times as well as the mild steel. If they applied the nickel steel tube to boilers, the boiler would last as long as the ship. Sir John Durston had stated that the life of the mild steel tubes averaged three years. That would mean that about 25 per cent. of the vessels would always be getting new tubes in—a serious look-out, which was endangering the efficiency of the fleet.

Sir William White said this was peculiarly an engineer's question, but it was one in which all concerned in ship construction must be greatly interested. He had had considerable experience of the use of alloys of nickel and steel in various directions. It had always seemed to him that that application which Mr. Riley had so consistently advocated was one of great promise. He well remembered the attempt, many years ago, to use nickel steel tubes in water-tube boilers. The story had reached him that these nickel steel tubes were ordered with a view to prevent corrosion, that they were very long in being delivered, and that when they did arrive they were exceedingly rusty. Nickel steel was a term which included a good deal, and with nickel at 2s. 6d. per lb. he could quite understand that people did not rush at the idea of using 25 per cent. of nickel in their steel unless there was very good reason for that large expense. A few years ago they were told that there were patents covering everything in the shape of alloy, and that the world's supply of nickel was in the hands of a very few people. These things were not true. If Mr. Yarrow would tell them what was the approximate relative cost of nickel steel and mild steel, he thought it would be seen that they had reached a stage when the alloy was within the reach of practical application. He wished to pay a personal tribute to Mr. Riley in that matter. The first application of nickel steel for armour-plate purposes, on a moderate scale, was made by Mr. Riley. Mr. Hadfield (Sheffield) had written a masterly monograph on all that had been done in the way of the alloys of nickel. If the members read that, they would know almost as much as was to be known on the subject at present. It was impossible to over estimate what they owed to Mr. Yarrow, not only for the extent and elegance of the research which he had brought before them, but for the extreme generosity which had prompted him, at the earliest possible moment, to come forward and give to them, and, through them, to the world, the result of an investigation which he was conscious must have far-reaching effects.

The Chairman wished to modify a statement of Sir William White's, to the effect that abroad they had not made more progress than we had with regard to nickel. The French had made very great progress in the adaptation of that very alloy to a vast number of purposes of domestic utility. He thought that the alloy was superior to silver to look at, and it had the further advantage of enormous strength. Mr. Riley, although for long a voice crying in the wilderness, was the real pioneer in this matter.

Mr. Yarrow, replying, stated that he did not attach great importance to the strength of the nickel steel for water-tubes. The strength was a very small question compared with the durability. Assuming, for argument's sake, that water-tube boilers were worth 20s. per foot of heating surface—his firm did not get that amount—although he believed the Belleville boiler would come out about that—the nickel steel tubes would come out 6s. a foot more than the mild steel, so that they had got to add 30 per cent. to the price of a boiler using nickel steel tubes. As to whether it was worth the additional outlay, that was for the people who bought the boilers to decide. Sir Austin Roberts wrote to his firm that the nickel iron alloys were very peculiar as regarded expansion by heat. An alloy of 25 per cent. of nickel expanded more than ordinary steel, but an alloy of 37 per cent. did not expand at all, showing that the 12 per cent. addition of nickel was quite sufficient to entirely change the character of the alloy.

Large Atlantic Cargo Steamers.

Mr. G. B Hunter next read a paper on "Large Atlantic Cargo Steamers." This we refer to in our Editorial Notes.

Professor Biles stated that he had had some experience in the preparation of designs for large cargo steamers. The reason that cargo steamers had not been larger sooner than they had been was one which was altogether beyond the control of the shipbuilder and the naval architect, and that was the size of the docks in which the ships had to be berthed. He remembered discussing this matter nearly 20 years ago with Captain Watson, the superintendent of the Cunard Line. They went carefully into the subject—just as a matter of interest—and found that the reason was that the docks and the harbours at both ends prevented the larger steamers being built. It was quite a fact to say that as soon as the harbours and docks were ready the shipowners and shipbuilders were quite as ready to put these large ships in. It was not obvious to everyone, perhaps, that large steamers were not always more profitable than smaller ones. With an unlimited volume of trade, the large steamer was inevitably the more profitable. With a limited volume of trade that was not so. The reason why large steamers were more profitable when they could get the limitation of draught removed was that the resistance, or H.P., to a given speed varied as the square of the dimensions, whereas the weight-carrying capacity varied as the cube of the dimensions. He was not quite sure that Mr. Hunter had chosen quite the best depth in proportion to the breadth. One disadvantage was that they did not get as much capacity as they might; another, that they got too much stability when they were going to the westward in ballast; whilst a third was that their steamer was not quite so strong. If a space in a ship was to be for safety and not for cargo carrying, it seemed only fair that that space should not be charged for tonnage. The position of the deep water ballast tanks in Mr. Hunter's ship did not seem to him to be the best position in all respects. He was not sure that tanks immediately forward and aft of the machinery space were not in a better position for the strength of the ship. Great strains came upon a ship when she was on the crest of a wave, and if they they put the weights amidships they reduced the strains. Mr. Hunter had said that until 1895 there were no British cargo steamers of more than 6,500 tons gross register. In 1892 the speaker was connected with the placing of an order of two steamers, both British vessels, which, he thought, were over 9,000 tons. He believed, indeed, that they were nearer 10,000 tons, and they had a carrying capacity of 10,000 tons deadweight. They were ordered in 1892, and finished at about the end of 1893, or the beginning of 1894. He wished to ask Mr. Hunter as to the strength of these large ships forward going to the westward in ballast. With their large flat surfaces they seemed to have a facility for coming to loggerheads with the sea and getting their bottoms staved in through the frames. Had Mr. Hunter had any experience of that sort of thing, and, if so, what precautions did he think it was necessary to take to avoid such an unfortunate state of affairs.

Mr. West, speaking of the position of the deep-water ballast tanks in the typical ship dealt with by the author, said that if the vessel was one of those which Professor Biles had been so successful in designing, with fine lines for a high speed, he would say undoubtedly that the proper place for these tanks was immediately before and abaft the machinery spaces. This, however, was a vessel in which the form was so much swelled out towards the two ends that it was necessary to shift the position. He used the word "necessary" advisedly, because he had seen cases where mischief had undoubtedly arisen from the large weight and water-ballast in the middle of the ship. Whether he would go as far as Mr. Hunter suggested was another matter which would have to be considered on the peculiar merits of each case. Inasmuch as these tanks must have a fore-and-aft division in order to make them seaworthy, that interfered a good deal with the convenience of using them for the stowage of cargo. He assumed that Mr. Hunter would in all cases carry his decks through, so as to give lateral support to the bulkheads. Apart from the shelter deck, they should have sufficient deck to give them girder enough for the length of the ship. Mr. Hunter spoke of an increase of 100 per cent. in the strength of propeller shafts. The speaker would join with Mr. Hunter in every desire to make propeller shafts as strong as possible. Of course, 100 per cent. of strength was a vastly different thing to 100 per cent. of diameter, but still he thought that such an increase was very much larger than was necessary. Where he had had a free hand he took from 30 to 50 per cent. more than Lloyd's rule. There were conditions in nature itself which prevented them from getting the full advantages in dimensions which they would like to have. He was afraid that there were times when no ships at all would be built if the profit which Mr. Hunter had indicated had to be earned. As long as they could construct their engines to drive one propeller without inconveniently increasing the size of the various parts, he believed that for cargo-carrying purposes a single screw had the advantage, because the cost of maintenance was very much less.

Mr. Corry referred to the fact that Professor Biles had taken exception to the position of the deep tanks as proposed by the author, and said he agreed with Mr. West that the tanks thus placed were not so very much out of place in vessels of this class. They could not always put these tanks exactly where they would like. Mr. Hunter had spoken of the construction of these different vessels, and had mentioned some of the weak spots in Lloyd's rules. He (the speaker) could bear out the remark that, to some extent, the rules were not either mechanically or practically what they should be, but the Committee of Lloyd's Register had recently made some modifications. Mr. Hunter had very properly brought before the meeting the question of the breakdown of the tail shafting. That was, without exception, the most critical part of a ship, and the one which required the most careful thought and attention. The speaker did not quite follow Mr. Hunter in his method of curing that. He would rather go in the way of making the shaft of better material, also of increasing the size, but not to the extent of 100 per cent. He would rather improve the material of the shaft.

Colonel Swan said he was quite in accord with the general conclusions of Mr. Hunter, particularly so in reference to the ballasting of large ships. It had always been a surprise to him that shipowners and underwriters had been content for so long to allow vessels to be sent across the Atlantic so insufficiently ballasted. Going back 25 or 30 years, he remembered that they made an attempt to introduce deep ballast tanks. Unfortunately, at that time tanks were not constructed as they ought to have been. Spaces which were used for ballasting got to be called tanks, and were looked upon both by shipowners and people who were supplying cargo as enclosed spaces where the cargo would be subjected to great deterioration. When the tank steamers came to be introduced, and the construction of bulkheads was found to be absolutely tight, a great many of these objections disappeared, and he had no hesitation in saying that there was now no difficulty whatever in constructing bulkheads which were absolutely tight. Water ballast holds could be made as dry and satisfactory as any other holds in the ship.

Mr. T. V. S. Angier, who prefaced his remarks by stating that he was the manager of a fleet of steamers, said that Mr. Hunter had always been in the van among enlightened and progressive shipbuilders in this country, and they owed him a debt of gratitude for teaching them to build the best class of ship for a long lifetime. The points of weakness that were found in vessels after they left the hands of the builders were not always brought to the builders' knowledge, and those who lived by the vessels were the best judges of those weak points. He would mention one of the great points that he had always found a defect in, so far as cargo ships were concerned at any rate. They all knew the terrific rate of corrosion in modern steel ships, and he contended, from his own experience, that the whole life of a ship was a question practically of scraping and painting. There was hardly any ship that he had gone over, inspecting the tanks, bilges, &c., that he had been able to inspect without actual personal risk. Practically, one needed to be a very clever monkey to get all over any ship of the present day. One of the first things that should be looked after was that there should be an absolutely safe and easy access to all the hidden parts of the ship, in order that they might see that these hidden parts were taken care of and kept, as far as possible, free from corrosion, that otherwise must take place if they were neglected. The usual thing was that these parts were neglected. Sailors were not enthusiasts in their work, and did not do more than they could help. It was not at all a trivial question in the life of a ship, and it was one that he wanted to press forward very materially. Water ballast was another great question of the day. No one had mentioned the experiment which had been tried in practically building a second skin for the ship, and utilising the double skin for water ballast; that was too complicated a matter, because it multiplied the difficulty of hidden spaces.

Mr. Leslie Denny, referring to the question of shafting, said he would like to know how many of the 173 vessels disabled in 1898 were disabled due to running across the Atlantic in water ballast. He thought that if the vessels were properly loaded down with ballast the 100 per cent. increased strength would not be required. As to twin-screws, he thought that there was no question of their advantages. He questioned whether so many breakages had occurred with twin-screws as with single propellers.

Mr. J. T. Milton said that, of the 173 vessels reported disabled last year through the failure of their shafting, 89 were classed with Lloyd's register. He could not speak of the rest. When they remembered that a very large proportion of British steamships were classed with Lloyd's, they could not think that 89 out of 173 was an unduly large number to be classed in that society. Of the 89, 26 were in ballast at the time of the disaster, 30 were stated to have been loaded, and there was no record as to the condition of the remaining 33. Out of the 89, 45 were engaged at the time of the casualty, or on their previous voyages in the Atlantic trades. If these vessels were not in ballast at the time of the breakages, it was probable that they were in ballast a short time before, because it was not always easy for Atlantic steamers to get cargo on the outward voyage. Mr. Hunter had stated that it was the bending stress on the shafts that caused the accidents. If they knew what caused the strain they might then learn how best to prevent it. The effect of bending strains on shafts was very much intensified by their irregular sections, the sections necessarily having liners put upon them. Great good would result from having these liners made continuous, and he thought that now that the attention of engineers had been drawn to the subject there was a growing tendency to put continuous liners on the shafts of all new large steamers. When Mr. Hunter suggested that they should make their shafts 100 per cent. stronger, he ought not to have forgotten the fact that the greater proportion of shafts that were running now were running well and giving satisfaction even at the present sizes. There were vessels which, when put into a particular trade or treated in a particular way, gave perfect satisfaction with their shafting. Other vessels, with the same scantlings and the same sizes, gave trouble. It all depended on how they were looked after. It was exceedingly difficult, sometimes, to persuade owners of the importance of drawing their shafts in. He knew of many instances where the shaft had been drawn in and condemned as soon as it was seen. It was the screw shaft which generally failed. The screw shaft was always made a little larger than the other shaft, and it failed because the strain to which it was subjected was an impulsive strain. It was questionable whether it would be wise to largely increase the strength of screw shafting without increasing the strength of the other shafting, which did not give any trouble at present. For a time some friends of his were troubled with broken propeller blades. Each time they renewed the blades they made them stronger. The result was that they did not have any further trouble with the blades, for now all the breakages had been transferred to the screw shafting.

Sir William White remarked that all of them, whether they were interested in merchant ship construction or not, must be deeply interested in the structural arrangements of such ships as these, with their enormous variations in load and condition in different voyages. With reference to the twin-screws, he ventured to ask Mr. Hunter by what process of analysis which satisfied his scientific mind he got out the narrow limits of 5 per cent. between the twin screw and the single screw. Perhaps, if he had put another calculator on to the work he might have found that the 5 per cent. was the other way. As ships grew in size, so the necessity for duplicate propellers was being universally recognised. Mr. Hunter had shown wonderful enterprise when he had attacked, with great daring and originality, the problem of mechanical appliances in the shipyard. He had been under great obligations to Mr. Hunter for information of the most generous character. The speaker was confident that British shipbuilders, if they would hold their own, must be careful to follow on the lines, or on alternative lines, to those on which Mr. Hunter had shown them such a lead.

Mr. Hunter, replying, said he had ventured to calculate upon the shelter deck as giving him some of the longitudinal strength which he required. The reason that he had not put the deep water tanks in the middle of the ship was that he thought the weights would have been too great. He apologised to Professor Biles for having overlooked the two ships which the Professor mentioned, but said their existence had very little or no effect on what he had to say. He did not think that the suggested increase in the strength of shafting—100 per cent.—would be excessive. They were dealing with a great evil. The breakdowns caused a very great loss of property. He did not think that he should be at all exaggerating if he said that these 173 ships had cost something like a quarter of a million of money, consequent on the failure of their propeller shafting. As to the 20 per cent. he had referred to, that only included 5 per cent. profit. If there was not a reasonable prospect of making 5 per cent. out of a ship he would advise the intending purchaser not to have it built.

The last paper, "On Thrust-Block Friction," was not read, owing to want of time. We make some reference to the same in our Editorial Notes.

Thanks to the Reception Committee.

Sir Edward Reed, on rising to perform the concluding portion of the strictly business session, said that Lord Hopetoun had been under considerable pressure in London for some time past, but he had stood nobly by his work until that morning, when considerations of health compelled him to give himself a little rest. They would see him, however, later on. He now asked the members to express their thanks to those who had given them such a splendid reception. He should like to refer, in the first place, to Lord Ravensworth, to whom that Institution would ever be indebted. Earl Ravensworth, by his high position and public services, and his large influence upon naval architecture, both in Parliament and in that Institution, as well as in many other ways, had great claims upon their consideration. It was a satisfaction to the members of the Institution that Lord Ravensworth had been able to attend their meeting that morning, and he would receive their most cordial wishes for his future. The number of public bodies that had contributed to the success of their proceedings was very large, and he included in the vote of thanks the Mayor and Corporation of Newcastle, the Tyne Improvement Commissioners, the Council of the Literary and Philosophical Society, the Sunderland Members, Sir W. G. Armstrong, Whitworth & Co., and the other firms who had permitted the members to visit their establishments. He expressed his pleasure at the considerable attendance of ladies at their meetings, and at the interest they had taken in the papers and in the debates. He was quite satisfied that in future they would have ladies contributing papers at their meetings.

Sir W. H. White seconded the vote of thanks, and expressed the obligation of the Institution to the members of the reception committee and others who had made the arrangements for their enjoyment, and he hoped for their profit also.

The motion was carried with acclamation.

Sir B. C. Browne, President of the North East Coast Institution of Engineers and Shipbuilders, responded. He hoped that 12 years would not be allowed to elapse again before the Institution paid another visit to the district. The Tees and Hartlepool had been disappointed that there had not been time to pay them a visit, and he suggested that, when next the Institution came to this district, the Tees and Hartlepool should be put in the first place, and that the Tyne and Wear should be the second and third lines of hospitality to fall back upon.

Earl Ravensworth, who was invited by Sir Edward Reed to associate himself in the response to the toast, was cordially received. He said it had given him great satisfaction to have been able to attend some of their meetings.

The business proceedings of the meetings then ended.

After the conclusion of the meeting, the members and their friends proceeded to the Corn Exchange, where luncheon had been provided by the Reception Committee.

After partaking of luncheon at the Town Hall the members of the Institution proceeded to the Fish Quay, where steamers where in waiting to take them on an excursion down the river. Those anxious to visit the shipyards went on board the *J. C. Stevenson*, which steamboat, was provided by the Tyne Commissioners, while those who did not desire to go ashore during the journey barked on the *Siren*, provided by the local Reception Committee. The former party was in charge of Mr. G. B. Hunter, and Mr. James Walker, engineer to the Tyne Commissioners, acted as guide to the latter. Those aboard the *J. C. Stevenson* visited the shipyard of Messrs. Swan & Hunter, and on reaching Jarrow, were received by the Mayor (Mr. Archbold) and other members of the Corporation, after which they went ashore to inspect the works of the Palmer Company. Light refreshments were provided by the proprietors of the works visited. The excursionists reached Tynemouth about six, and returned to Newcastle by special train. Though rain began to fall about five o'clock, the outing proved most enjoyable.

Shipbuilding and Dock Building Yards of C. S. Swan & Hunter, Limited, Wallsend-on-Tyne.

The original shipyard was laid out in the year 1872, and is now what is known as the company's West Yard, the area of which is about seven acres. The ground was laid out with five or six slips for building vessels of a small tonnage. In 1874 the business was taken over by the late Mr. C. S. Swan, and it was carried on by him until his death in 1879. At the beginning of the next year, 1880, Mr. G. B. Hunter took over the control of the business, under the style of C. S. Swan & Hunter, since which time the amount of work turned out and the area of the yards have largely increased. At first the ships built were principally small cargo steamers; but gradually the sizes increased and passenger vessels were built and equipped, an interesting vessel of this class being the *Courier*, launched in the summer of 1887, she being a vessel 221 ft. in length between perpendiculars, 30 ft. by 13 ft. 3 in., with single screw, and having what was at that time the high speed of 17½ knots. This vessel is still doing excellent work in her original trade between Melbourne, Victoria, and Geelong.

In the year 1883 it was found necessary to extend the area of the yard, and the ground known as the East Yard was acquired and laid out with shipbuilding machinery of the best type, and it is in this yard that the principal extensions have been made, the workshops, sheds, and machinery having been gradually increased and kept up to date in order to cope with the building of the very largest class of merchant vessels, and it is to successfully undertake the building of this class of vessel that the large ship sheds seen in this yard have been erected. These sheds (designed by Mr. G. B. Hunter and Mr. F. Caws, architect, Sunderland) are each 500 ft. in length, the eastern one being 68 ft. wide in the clear, and the western 71 ft. 6 in. clear in width, the inside height being 83 ft. clear at the fore end, and 80 ft. at the after end. Each shed is provided with two electric travelling cranes with revolving jibs working below the cranes, capable of lifting a weight of three tons, and of travelling at a speed of 300 ft. a minute, and making a complete revolution in a little less than half a minute. On the outside of the east shed is a travelling cantilever crane, also electric, to span the third berth, this crane being designed to lift three tons at any distance up to 65 ft. outwards from the roof, and to travel 500 ft. On each side of each shed two shelves will be noticed, from which vessels are shored instead of carrying the shores to the ground, thus saving a considerable amount of timber and labour. The roof being covered with glass, work can proceed without interruption from bad weather; the advantage of which was during last winter amply demonstrated. The temperature under the sheds is found to be cooler in summer and warmer in winter than outside. The electric current for driving the various motors attached to the cranes and machines is generated in a power-house situated at the central part of the yards, which contains two compound engines, the larger capable of developing 200 H.P. and the smaller 160 H.P. There is also a small vertical compound engine. This engine is used when working overtime and on holidays. These engines drive five large dynamos and one small one, which latter is used for exciting the larger dynamos and also for charging the accumulators which supply the light for the offices. The steam necessary to drive these generating engines is supplied by two Babcock & Wilcox water-tube boilers, and in order to ensure a supply of pure water to these boilers and also to increase the economy of the plant, an atmospheric condenser is fitted on the roof over the boilers.

In 1895 the firm was transformed into a limited liability company, Messrs. G. B. Hunter, J. Price, T. H. Bainbridge, W. Denton, and C. S. Swan being the directors, and the shipyard lying to the west of the original yard, and which was the yard of Messrs. Schlesinger, Davis & Co., was added for the purpose of building the largest class of floating docks, dock gates, and work of that class. The most notable of such docks was the one that was built, launched, and fitted out complete from this yard for the Spanish Government, and towed from the Tyne to Havana in 1897. Other large floating docks have been built for Stettin, Shields, and Wallsend. The area of the various yards is now about 33 acres, with a river frontage of nearly one-third of a mile; and the output has increased, until last year the amount of tonnage launched was 68,696 tons gross register, being the second largest output of that year.

Among other vessels recently built in these yards are the mail steamers *Warrimoo* and *Miowera*, launched in 1892, and which are now running with passengers and mails between Sydney, N.S.W., and Vancouver, B.C., calling *en route* at Brisbane, Fiji, and Honolulu; the *Milwaukee*, *Monarch*, and *Mount Royal*, each of between 11,000 and 12,000 tons deadweight and 18,000 tons cubic capacity, for the Atlantic cargo and cattle service of Messrs. Elder, Dempster & Co., Liverpool; the *Maori*, *Aotea*, and *Tokomaru*, for the Shaw, Savill & Albion Co.'s New Zealand passenger and frozen meat service; and the *Ultonia*, a cargo and passenger steamer of 11,000 tons deadweight capacity, launched last year for the Cunard Company for their Boston service; the *America Maru*, 17½ knots, for the Toyo Kisen Kabushiki Kaisha, of Tokio, Japan, to initiate a new mail and passenger line between San Francisco, Japan, and China; *Saint Andrew*, a four-masted twin-screw steamer, for Messrs. Rankin, Gilmour & Co., Liverpool.

The following vessels are now in progress: The *Kumara*, a large single-screw vessel 440 ft. in length overall, 54 ft. beam, and 32 ft. 10 in. depth, moulded, and built for the Shaw, Savill & Albion Co. Limited, for their New Zealand frozen mutton trade, and which will be capable of carrying 80,000 to 100,000 frozen sheep on each trip. This vessel is at present in Hartlepool, having her machinery fitted on board. On the west berth of the west yard is a vessel for the Atlantic service of Messrs. Elder, Dempster & Co., Liverpool, 348 ft. by 48 ft. by 26 ft. 10 in.; carrying capacity, 5,850 tons deadweight. In the next berth is a steamer 392 ft. by 46 ft. 3 in. by 31 ft., for Messrs. Rankin, Gilmour & Co., of Liverpool, 6,800 tons deadweight, her intended trade being between Antwerp and Newport News. On the eastern berth in this yard is a 5,500 tons deadweight tank steamer for carrying petroleum in bulk, 355 ft. by 47 ft. by 29 ft., building for Messrs. C. T. Bowring & Co., of Liverpool.

In the east yard under the west shed a large twin vessel is being laid down, 483 ft. by 56 ft. by 34 ft. 10 in., to carry about 10,700 tons deadweight and 18,000 tons cubic capacity, to steam 12 knots average in the Atlantic Line of Messrs. Elder, Dempster & Co. Under the eastern shed is the largest vessel the company has yet built and also the largest ever built on this coast. This is a passenger and cargo liner for the Cunard Co., and is 600 ft. long over all, 64 ft. 6 in. beam and 49 ft. 6 in. deep to the shelter deck. She is intended for their New York and Liverpool service, and will carry 150 first-class passengers, 1,000 steerage passengers, half of which will be provided with two, four, and six-berthed state rooms. At the after ends, stalls will be provided for 800 head of cattle and 80 horses. The average speed at sea is intended to be 15 knots, the power being obtained from two sets of quadruple expansion balanced engines working twin-screws. On the easternmost berth is a vessel, 472 ft. by 52 ft. by 34 ft. 2 in., for Messrs. Thos. Wilson, Sons & Co., of Hull, which is also a twin-screw vessel and for the Atlantic cattle trade.

Palmers' Shipbuilding and Iron Company, Limited, Jarrow-on-Tyne.

Evidence that the district of the Tyne was from an early period a highly important shipbuilding centre, is afforded by the fact that, writing more than a century and a half ago, Defoe, in speaking of the Tyne, says: "They build ships here to perfection, I mean as to strength and firmness, and to bear the sea." Since this was written the world has moved at a marvellous pace, and in shipbuilding, more than in any other branch of national industry, progress has been made by leaps and bounds, and the vessels of to-day have no more resemblance to those of Defoe's days than has the "Flying Scotchman" express train in common with the cumbrous vehicles in use for travelling at the time when George II. ascended the throne—a date contemporary with that of the publication of Defoe's work from which the above sentence is quoted. In one respect, however, things remain now as they apparently were then. The river Tyne is still unequalled for its shipbuilding industry, and neither on the Thames nor the Clyde is to be found a private shipbuilding yard which at all approaches in extent or resources the establishment of Palmers' Shipbuilding and Iron Co., Limited. to which we are about to draw attention.

Sir Charles Mark Palmer, Bart, M.P., the founder of the company, and its chairman until 1893, when he retired, has played a leading part in the introduction of iron shipbuilding. About the year 1850 the carriage of coal by railway began seriously to affect the sale of North country coal in the London market, and it became, therefore, essential in the interest of coal owners to devise some means by which the staple produce of the district could be conveyed to London in an expeditious, regular, and economical manner. To accomplish this object was the problem which Sir (then Mr.) Charles Palmer set himself, and with that end in view he designed an iron screw steamer, the *John Bowes*, which had a carrying capacity of 650 tons, and was capable of an average speed of nine miles per hour. To the success of this experiment, more than to anything else, is due the truly marvellous development of the shipbuilding industry on the Tyne as well as elsewhere. The new departure met, originally, with much opposition; Mr. Palmer, however, felt confident of the result, and time has amply demonstrated the soundness of his theories and the wisdom of his plan. Nay, more, as illustrating the quality of the material and the excellence of the workmanship, embodied even in those early days in the vessels produced by the firm, let it be placed upon record that the *John Bowes* is still doing as good service as it did when first launched, and yet over forty-four years have elapsed! Many other instances of a like character might be adduced redounding equally to the credit of the company.

The shipbuilding yard was established in 1851, down to which time Jarrow was a mere pitmen's village, inhabited by the small number of persons who were employed at a colliery in the neighbourhood. This colliery has long since been exhausted and filled up; and had it not been for Messrs.

Palmers' wisely directed enterprise, Jarrow would probably to-day have no existence in the commercial annals of this country. As it is, the place has become a flourishing town, with a population of over 40,000, and no one can pass through its streets without being impressed with the signs of prosperity which are manifested on every hand, but without acknowledging that Messrs. Palmer, by establishing here their works of unequalled extent, have conferred lasting blessings—physical and social—upon the working population of the Tyne district. What—looking at it from a broader point of view—their unaided efforts have done for the nation in enabling us to maintain our prestige as the greatest and best shipbuilders in the world, and in increasing our means of defence by supplying to the Navy some of its finest and most powerful ironclads, it is the object of the following notes to bring into prominence.

The company's works cover an area of nearly 100 acres, and have a river frontage of 4,000 ft., while the number of building slips available is fifteen. Accommodation for repairing purposes is also provided on a large scale, including, as it does, a graving dock, 440 ft. long by 70 ft. wide, and a slipway, 600 ft. long, worked by hydraulic lifting gear. To enable the reader to form some faint notion of what is implied by Palmers' Shipbuilding and Iron Works, let us state that they include within themselves the entire range of operations, from the smelting of the ironstone to the complete equipment of iron or steel vessels of all sizes.

Each of the five blast furnaces in operation is about 85 ft. high, of 24 ft. diameter at the boshes, and from 8½ ft. to 10 ft. in the hearth. They are capable of producing together over 4,000 tons of pig-iron per week, more than one-half of which quantity is used in the company's works. Taking the average, the production of pig-iron amounts to nearly 250,000 tons per annum, and that of finished iron and steel to 100,000 tons. The blast is heated to about 1,500 degs. Fahr. in "Whitwell" hot-air firebrick stoves, and there are 18 kilns available for calcining the Cleveland ironstone.

In connection with the steel works and rolling mills, which are of the most modern character, there are two forge engines with 36-in. cylinders, one of 4 ft and the other of 5 ft. stroke, each driving a roll train and four pairs of 22 in. rolls. Besides these, there are two plate mills and 10 mill furnaces, with an output of about 1,200 tons of finished boiler and ship plates weekly. Each mill has two pairs of 24 in. rolls, reversed by clutch and crabs. They have further a bar mill, with two pairs of rolls, driven by a 24 in. cylinder, which produces weekly 120 tons. A fourth mill, with four pair of rolls, driven by two 30 in. cylinders, with 4 ft. stroke, produces about 300 tons of plates per week. In addition to the above, there is a large angle and bar mill, driven by a single engine having a 36 in. cylinder and a 4 ft. stroke, which is capable of rolling the very largest angles used in the trade; and there is also a sheet mill in the forge. Attached to the rolling mills are shears, circular saws, punching and straightening presses, and other appliances for the construction of iron and steel ships built on the river frontage of the Jarrow works.

Prodigious as are the foregoing figures, they only relate to one section of this immense shipbuilding yard. The adjoining department is devoted to the production of engines, and its manufacturing capacity may be judged from the fact that here can be finished from 30 to 40 pairs of marine engines, with their boilers, in one year. This department, too, we may add, produces its own iron and brass castings and forgings, and is thus altogether self-contained. In the boiler shops vertical rolls for rolling long boiler shell plates were first used, and the original rolls may be still seen in operation. Allusion has been made to the productive capacity of this portion of the establishment; and that what they have said on this head is not mere theoretical assumption may be inferred from the fact that as many as 36 pairs of engines of 7,300 nominal, and 39,240 I.H.P. have been turned out in one year.

Next in order for mention comes the shipbuilding department proper, which occupies the east end of the company's works. It contains a large graving-dock capable of accommodating vessels up to 440 ft. long, and also, amongst others, a very fine patent slip, lately fitted with hydraulic hauling gear. The building slips are suitable for every kind of vessel up to 500 ft. in length, and together with those in the Howden branch of the works, on the opposite side of the river, are capable of launching 70,000 tons of shipping annually.

Let us adduce a few more figures which will demonstrate the unequalled productive capacity of Messrs. Palmer as shipbuilders. In 1881 the output amounted to 48,000 tons of shipping. During the following year 29 vessels were built, of an aggregate tonnage of 61,489 tons, or an average of 1,183 tons per week. Even these very high figures have, however, since been exceeded, the total output in the year 1889 having been 28 vessels, representing a gross register tonnage of 64,669 tons, or the enormous average per week of about 1,347 tons. All these ships, be it remembered, have also been fitted with engines and boilers built at the works. The vessels at present in course of construction, or on order, consist of several very large passenger and cargo steamers of nearly 11,000 tons deadweight, a first-class battleship, and several torpedo boat destroyers for the British Government, which are to have a speed of 30 knots. They have quite recently delivered to our Admiralty nine vessels of this high-class, as well as two cruisers, all of which have given the greatest satisfaction in their official steam trials. The record of the Palmer Co. in naval work is noteworthy, inasmuch as they have built 50 war vessels for the English Navy, among which is to be found every type of fighting ship, including the two first-class battleships, *Resolution* and *Revenge*, built under the Naval Defence Act of 1889, and the last of which was launched in November, 1892,, and delivered complete in October, 1893, being, we believe, the shortest time in which a battleship of her size has been completed.

It may be well to mention, in conclusion, that the company under notice stands out pre-eminent from all its competitors. The Jarrow Works are the largest and busiest of any private shipbuilding yard in existence, and although some of our own Government dockyards are larger in area, they can none of them—neither Chatham, Devonport, nor even Portsmouth—compare with the works in question for the extent of the operations carried on.

In the evening, at the Hancock Museum, the members of the Institute of Naval Architects were entertained at a soirée by the local Reception Committee. There was a large and brilliant attendance, against which the unfavourable weather seemed hardly to have militated. The main reception room presented a most animated and picturesque appearance, the bright dresses worn by the ladies lighting up the sombre hall with a singularly pleasing effect. Nearly all the local members were present, with many of the visitors from a distance.

The members of the Institution devoted Friday, July 21st, to an excursion to Sunderland for the purpose of inspecting the pier works and various shipbuilding and engineering establishments on the Weir. A special train left Newcastle at 9.45 a.m. and arrived at Monkwearmouth Station, Sunderland, shortly after 10 o'clock. The Mayor of Sunderland (Alderman Bruce) and the Sunderland members of the reception committee had assembled at the station to receive the members of the Institution. The party, numbering 200, proceeded by tram-cars to the Roker Pier. The visitors were there received by Sir James Laing, chairman of the River Weir Commissioners, Sir Hedworth Williamson, Messrs. G. R. Booth, R. M. Hudson, R. H. Gayner, C. H. Dodds (traffic manager), H. H. Wake (engineer), and J. G Morris (clerk to the River Weir Commissioners).

At the entrance to the North Pier there was an interesting display of models. That which attracted most attention was a very perfect representation of the mammoth crane, showing the manner of the construction of the pier, which was also illustrated by a coloured diagram showing a section of the work. There was also a model of the lighthouse which will be erected on the roundhead of the Roker Pier on completion, and of the concrete barge. showing the disposition of the concrete bags—the long ones being alternated with short ones. The party then turned towards the pier, a large number being carried along on the car A large red granite faced block, weighing some 50 tons, had been taken to the end of the pier, it having been arranged that this huge block should be formally laid by Lord Hopetoun. In the centre was a grey granite block in which the words had been carved, "Hopetoun, 21·9·99."

Mr. Wake, the engineer to the Commissioners, gave a brief account of the new works, which, he said, consisted of two harbour piers. The Roker Pier foundation-stone was laid in 1885, on September 14th, by Sir James Laing. The South Pier foundation-blocks were laid in 1892 by Mr. R. M. Hudson and Mr. Robert Thompson, chairman of the Works Committee. Since then different blocks had been laid by various notable personages. Enclosed in the docks was a water area of 50½ acres, and between the piers there was an area of 153 acres. There were three miles of quayage round their works, and they had a lock 480 ft. long by 90 ft. wide, with 65 ft. gateways. The amount of coal shipped from the port last year was 4½ million tons. The Roker Pier was 2,790 ft. long, and they had only 38 ft. to finish until the roundhead was ready for completion. This would be completed by a steel or iron caisson loaded with concrete, and when placed in position would contain a mass of 13,000 tons to low-water mark; the roundhead and lighthouse when completed would weigh 28,800 tons. This work was expected to be completed next year. When the piers were finished they would have smooth water in all weathers inside. The foundation of the piers was composed of bags of concrete lowered into *situ*, the structure above being granite-faced blocks weighing from 43 to 51 tons. Before the piers were started they had only 3 ft. to 4 ft. of water on the bar, but they had gained some 12 ft. on this, which was maintained without dredging, and by the scour of the tide only. This showed that they were proceeding on right lines, or at least they believed so. The length of the South Pier was 2,884 ft., of which 1,763 were completed. He mentioned that the spray had been 107 ft. above high water, when heavy seas prevailed, yet it was satisfactory to note that they had not lost a life, had never killed a man, and had not lost a piece of their work.

The Earl of Hopetoun then laid the large block that had previously been brought from the shore end of the pier, and declared it well and truly laid. He said he was very proud that the name of the president of the Institution of Naval Architects should be handed down to posterity on such a fine work as that. He thought they would agree with him in taking that opportunity of thanking their hosts for their kindness in showing them so much to interest them. He wished good luck to the port of Sunderland, and hoped they would reap the reward of their pluck at having spent so much money.

The visitors then left the pier, and a number proceeded to Messrs. J. L. Thompson's shipyard, while others went to Messrs. Dickinson's engine works, By far the greater number, however, proceeded along the pier works to the dock basin, where the steamboat *Siren* awaited their pleasure. A short trip to sea ensued, and proved thoroughly enjoyable. Refreshments were served on board, and the proceedings were most pleasant. The vessel returned to the port by the south entrance, and at once proceeded to the Havelock warehouse, where luncheon was served, the visitors being the guests of the reception committee.

The party again boarded the *Siren*, and visited the North-Eastern Marine Engineering Works, Messrs. George Clark's, engineers, and the shipyards of Messrs. Bartram & Sons, the Sunderland Shipbuilding Co., Sir James Laing (Deptford), Messrs. Short Bros., and also Messrs. Doxford & Sons' shipbuilding and engineering establishment, where they went over a new "turret" steamer recently launched for the Clan Line, of Glasgow, in which great interest was evinced, many of the members not having previously seen a vessel of this construction. The process of "joggling" ships' plates was also watched, and then an adjournment was made to the offices, the model hall of which was greatly admired. After light refreshments had been partaken of here the visitors entrained for Newcastle, having spent an exceedingly pleasant day.

Visit to Cragside.

No more pleasing termination to the summer meetings of the Institution of Naval Architects could have been arranged than the excursion to Cragside, which took place on Saturday, July 22nd. Throughout the week there was a happy combination of pleasure with business, and the members made many interesting visits to places on Tyneside and Wearside; but it was the general feeling that the earlier expeditions did not, in any instance, prove so wholly enjoyable as that which, at the kind invitation of Lord Armstrong, was made to his beautiful home at Cragside. The party, which numbered over 400, a goodly proportion being ladies, travelled by saloon carriages to Rothbury, two special trains being required for the purpose. Newcastle was left shortly after 9 o'clock, the journey to Rothbury occupying about an hour and a-half. Mr. W. A. Watson-Armstrong kindly came to the railway station to welcome the visitors, and a large number of conveyances were in waiting to convey them to Cragside. Many people, however, preferred to cover the distance on foot, and as the weather was all that one could wish for, the walk proved most enjoyable.

Lord Armstrong's picturesque mansion, Cragside, was begun in 1863, designed by Norman Shaw, R.A., is built in a composite style of architecture, partly Gothic and partly Elizabethan. The house forms a strikingly effective picture when contrasted with the rugged scenery in the background. Lord Armstrong, unfortunately, was not in a state of health which would warrant him undergoing the excitement of meeting so large a number of visitors, although his lordship had looked forward to the event with interest, and would most gladly have discharged the duties of host had his health permitted him to do so.

The visitors were entertained to luncheon in a huge marquee erected on the grounds This terminated the proceedings, and the members and their friends left Rothbury shortly after 2 p.m., reaching Newcastle between four and five. The excursion was a most enjoyable termination to a very successful meeting. Thanks are due to the Reception Committee, President, and Secretary of the Institution, also A. J. Cochrane, Esq., and John Duckitt, Esq., joint Hon. Secretaries.

SOME EXPERIMENTS HAVING REFERENCE TO THE DURABILITY OF WATER-TUBE BOILERS.*

By A. F. Yarrow, Esq., Vice-President.

FEELING sure that anything which may tend to increase the durability of water-tube boilers will interest the members of our institution, I have much pleasure in laying before you the results of some experiments which we have recently carried out with a view to ascertain the comparative merits of nickel steel tubes and tubes of mild steel, such as have hitherto been used in water-tube boilers.

The nickel steel to which this paper refers is an alloy, having from 20 to 25 per cent. of nickel, and in these experiments we have tried to repeat as nearly as possible the worst conditions as regards wear and tear to which tubes in water-tube boilers are subjected.

The deterioration of the tubes is probably owing—

(1) To the action of acids in the water, due to grease, which, in spite of every precaution, finds its way into the boiler.

(2) To the tubes becoming overheated and oxidising on the outside, through contact with the hot gases when passing from the furnace to the uptake.

(3) To the action of the steam, which, if superheated, decomposes, causing deterioration on the inside of the tubes.

The last two conditions occur when the tubes, from defective circulation, shortness of water, or from the collection of scale, become overheated.

Table I. records what we have termed the "Corrosion Test" It will be seen that the piece of nickel steel tube A was compared with the piece of mild steel tube B, the original weights of which were 190 and 186 grammes respectively. Both the tubes were immersed in the same dilute solution of hydrochloric acid for various periods, as indicated. The duration of the tests varied, as shown, from 21 to 168 hours, making a total number of hours for all the trials of 533. The ultimate loss of weight in the nickel steel tube was 5 grammes, and in the mild steel tube 98 grammes. It will be seen that the original weights of the two specimens in this case did not accurately agree; but in the second trial, E and F, the tubes were of the same original weight, namely, 188 grammes each. The ultimate loss of weight was found to be 7 grammes with the nickel steel tube E, and 100 grammes with the mild steel tube F.

The upshot of the above tests, it will be seen, is that the loss of weight in the first series of tests of the nickel steel tube amounted to 5 grammes, being 2·63 per cent., and in the mild steel tube to 98 grammes, being 52·68 per cent. In the second series of experiments the loss of weight of the nickel steel tube was 7 grammes, being 3·72 per cent., and the mild steel tube 100 grammes, being 53·19 per cent. The average loss of weight in the mild steel tube was therefore 16½ times what it was in the nickel steel tube.

The tubes as they appeared on the termination of this experiment are shown on Plate I.

It may be contended that the relative corrosion of the two specimens when using dilute hydrochloric acid does not correspond with what it would be with such acids as are present in

---

*[Read at the Summer Meeting of the Fortieth Session of the Institution of Naval Architects, July 20th, 1899, Sir Edward Reed in the chair.]

TABLE I.—CORROSION TEST.

boilers under working conditions, but it is not unreasonable to suppose that it may serve as a guide.

We will now turn to Table II., which records what we have termed the "Fire Test." This was conducted in the following way:—Two tubes were placed side by side in a small brick furnace, where they were heated to the same extent, and in every way were practically under the same conditions. The loss of weight of each tube due to the oxidation after they had been in a very heated state is indicated by the weights given. It will be seen that the original weight of the nickel steel tube C was 192 grammes, and the mild steel tube D was 185 grammes. The total loss of weight in this series of tests was, in the case of the nickel steel tube, 47 grammes, or 24·47 per cent., and of the mild steel tube 145 grammes, or 78·37 per cent. In this case also the original weights of the two pieces of tube were not exactly the same, and we therefore repeated the experiments, as shown by G and H, in which the weights of the two tubes were identical, namely, 188 grammes, and the loss of weight was found in the nickel steel tube to be 52 grammes, or 27·66 per cent., and of the mild steel tube 143 grammes, or 76·06 per cent. The average loss in weight in the mild steel tube was, therefore, 2·9 times what it was in the nickel steel tube.

These tubes as they appeared on the termination of this experiment are shown on Plate I.

These results were submitted to Sir John Durston, and he pointed out that the experiments did not accurately conform to all the conditions under which boilers are worked, inasmuch as the tubes, in the case of a boiler when the heating surfaces are not in close contact with the water inside, are subject not only to the action of the gases on the outside, but to that of the superheated steam on the inside. The correctness of this view is unquestionable, and we consequently tested two tubes having a length of 1 ft. 8⅝ in. by a diameter of 1 in. outside by 14 L.S.G. This experiment we termed the "Superheated Steam Test," and I would now beg reference to Plate II., Fig. 1. The experiment was carried out in the following manner:—Two tubes, one of nickel steel N, and the other of mild steel O, were placed side by side in a small brick furnace; at one end of each tube steam was supplied at 60 lbs. pressure, it being allowed to issue slowly from the opposite end of each tube, thus ensuring the steam being highly superheated. The result of this experiment is shown on the diagram. The original weight of each tube was 612 grammes. After the experiment had proceeded ten hours, it was stopped, as the mild steel tube O gave out, steam issuing from the defective place. The loss of weight in the case of the nickel steel tube N was 12·7 grammes, and in that of the mild steel tube O, 85·2 grammes. Deterioration in this case is due partly to the action of the steam inside the tube, and partly to that of the gases outside.

The loss of weight of a boiler tube from deterioration at the commencement of its life being much less rapid than towards the end of its life, therefore the loss of weight cannot be considered as a quantitative guide for durability, and we continued the superheated steam test as follows:—After the mild steel tube O had burnt through and allowed the steam to escape, we replaced it by another similar mild steel tube P, corresponding to what would be done in retubing a boiler. The experiment was then continued, and it was found this second mild steel tube

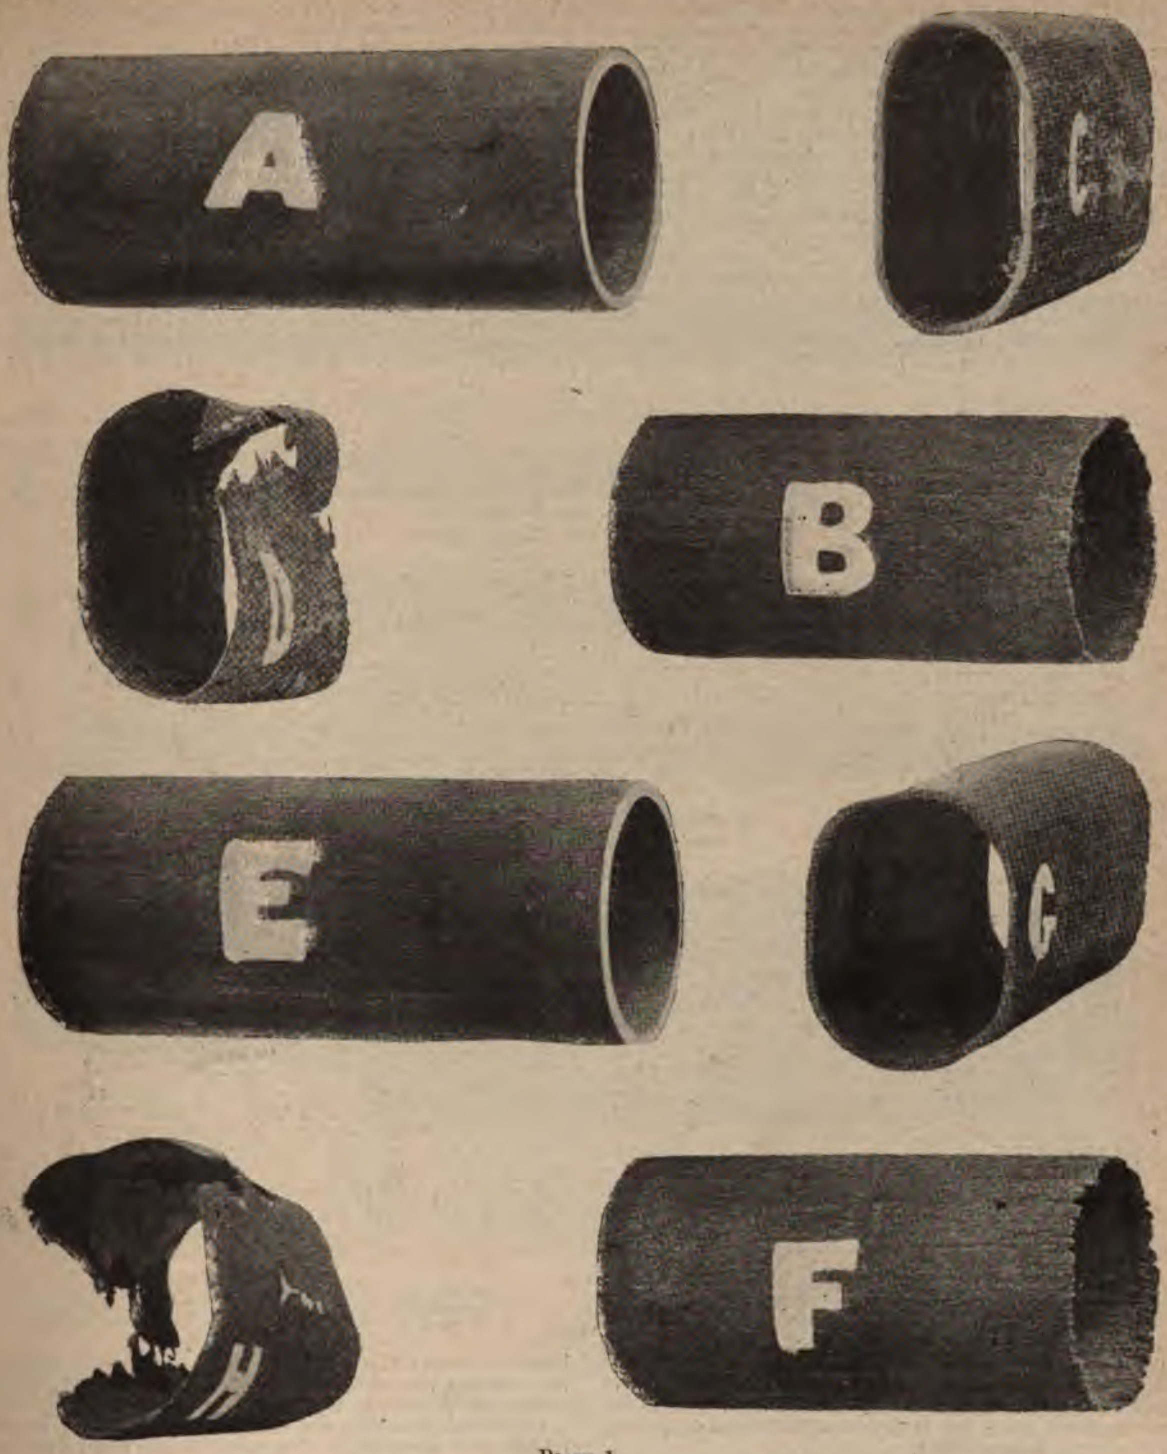

PLATE 1.

gave way and the steam burst through after eight hours, the nickel steel tube still remaining intact. We then substituted this burnt mild steel tube by another tube R, and we found that after three hours the nickel steel tube gave out.

Every two hours during these experiments the position of the tubes was changed about, not only end for end, but side for side, so as to ensure that both tubes were subjected to the same conditions.

The tubes as they appeared at the termination of this experiment are shown on Plate III.

It will be seen from this that the durability of the nickel steel tube corresponded to 21 hours, and the mean durability of the first two mild steel tubes to nine hours. I think, therefore, there is a reasonable probability that from this cause of deterioration a boiler would require to be retubed 2⅓ times as often with mild steel tubes as it would with nickel steel tubes.

In the foregoing experiments the tubes were ungalvanised. Had the mild steel tubes been galvanised there would have been a small addition to their durability, the extent of which is a matter of doubt.

We then made some trials with a view to ascertain the relative expansion by heat of the two materials. Two tubes were taken, 22 in. long, 1 in. in diameter, No. 16 L.S.G. They were inserted in a large tube and heated gradually up to a dull red for about three-fifths of their length. The tubes were fastened together at one end and projected freely and independently beyond the furnace at the other. A record of the expansion of each of the tubes was made by means of a trammel, and their expansion accurately determined. It was found that the expansion of the nickel steel tube was considerably greater than that of the mild steel tube. Plate II., Fig. 2, shows the gradual increase of length during the process of heating up, which occupied 330 seconds, and it was found that the relative expansion was approximately as 3 to 4, the nickel steel expanding the most. The object of this experiment was to ascertain whether there was sufficient difference in the expansion and contraction of the two materials to cause trouble when nickel steel tubes are placed within a group of tubes of mild steel. The result points to possible risk in this direction, and, should it be desired to place nickel steel tubes in those parts of the boiler where deterioration proceeds with the greatest rapidity, and mild steel tubes elsewhere, this variation of expansion should be borne in mind. I am not prepared to say it is a source of risk; but it is one of those practical points which must not be overlooked.

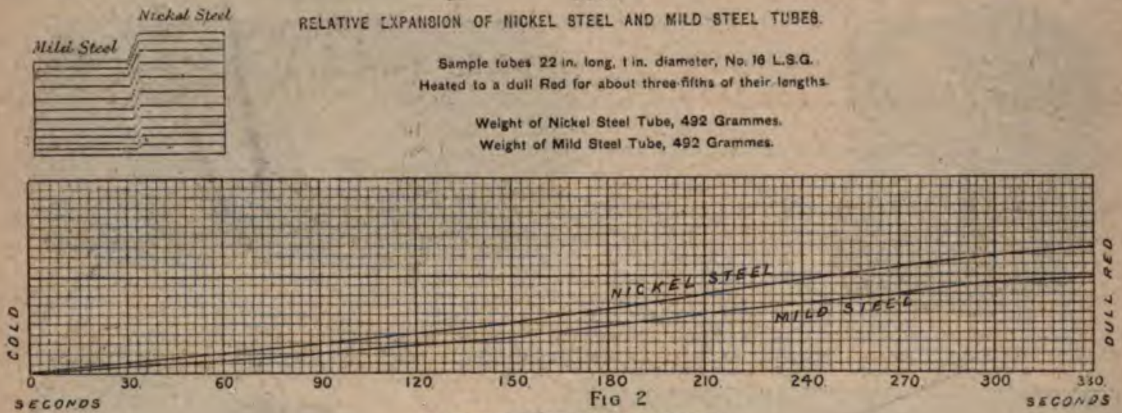

Fig 2

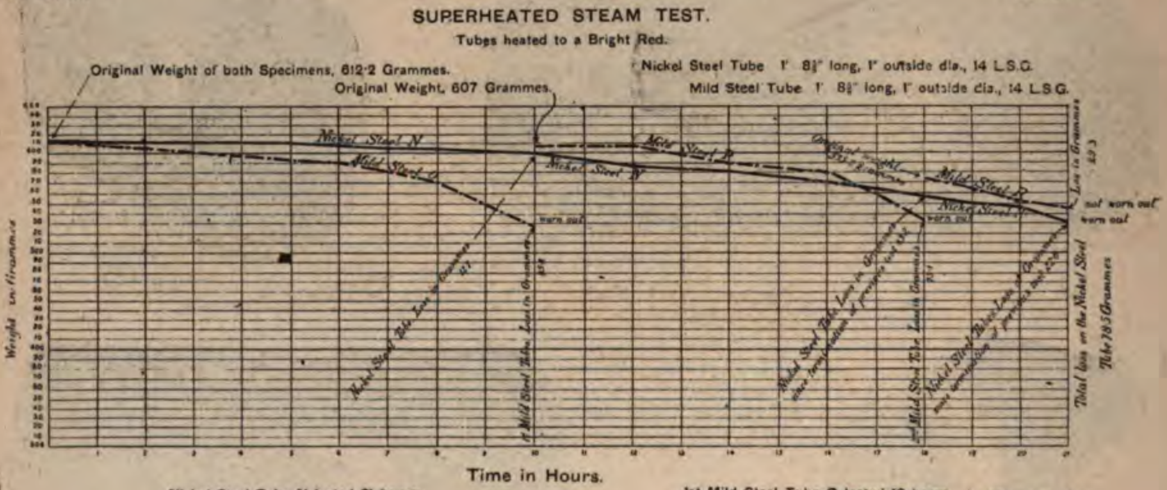

Nickel Steel Tube N lasted 21 hours.

1st Mild Steel Tube O lasted 10 hours
2nd Mild Steel Tube P lasted 8 hours } Mean 9 hours.

Fig 1

Plate 2.

All the specimens that I have referred to are here for your inspection, and I would remark that the tubes corresponding to Tables I. and II. were not of quite the same length, the nickel steel tubes being in all cases somewhat longer than the mild steel tubes, and therefore so far as this difference in size is concerned it was unfavourable to the nickel steel tubes, which exposed a larger surface to deterioration.

To illustrate the suitability of nickel steel from a mechanical point of view, I have brought a few specimens (see Plate IV., also No. 1, Plate III.). Nos. 1 to 6 illustrate its ductility, *which* is almost equal to that obtainable with mild steel. I would submit that the ductility of these samples is amply sufficient for all practical purposes. Nickel steel is considerably tougher in working than mild steel; it involves more labour, and causes greater wear and tear of the tools employed in expanding and bell-mouthing, to which latter operation we have always attached the highest importance. The ductility does not seem to be impaired by sudden changes of temperature, as shown by specimens Nos. 7 and 8, these specimens having been bent after being heated and chilled.

As regards cost, sufficient has not yet been done to know what the probable ultimate price may be; but, doubtless, it will be reduced from what it now is, if tubes of this alloy are introduced. Even at the present stage, judging from the experiments described, it is not unreasonable to expect that the longer life of the nickel steel will prove fully proportionate to its higher price, if the cost of the more frequent replacing of the mild steel tubes is taken into account; and if this surmise be correct, clearly a decided gain would be obtained by the greater trustworthiness of boilers with nickel steel tubes, and by avoiding the frequent loss of time involved in retubing operations, during which period the boiler is laid up.

I would observe that we have tried experiments as to the comparative durability of nickel steel having small percentages of nickel, say, up to 5 per cent., and have found that a very slight increase of durability is obtained by such alloys, but not sufficient to render them of any practical value for boiler tubes.

Summary.

From the foregoing experiments, I think it not unreasonable to assume that nickel steel (20 to 25 per cent. nickel) boiler tubes will have as regards acid corrosion, a vastly longer life than those of mild steel, and, as regards deterioration from the action of heated gases or steam, at least twice the durabilty of mild steel.

Before concluding, I should like to mention that these experiments have been carried out in consequence of our attention having been drawn to the probable advantage of nickel steel tubes by Mr. Andreæ, the engineer-in-chief of the Dutch Navy.

In these remarks only a few points have been touched upon in relation to nickel steel, but those members who may be desirous of looking further into the matter I would refer to the valuable paper recently read by Mr. Hadfield before the Institution of Civil Engineers.

I should also like to add that these experiments have been carried out under the direct supervision of my friend Mr. Crush, to whom I am much indebted for the care he has given to this investigation.

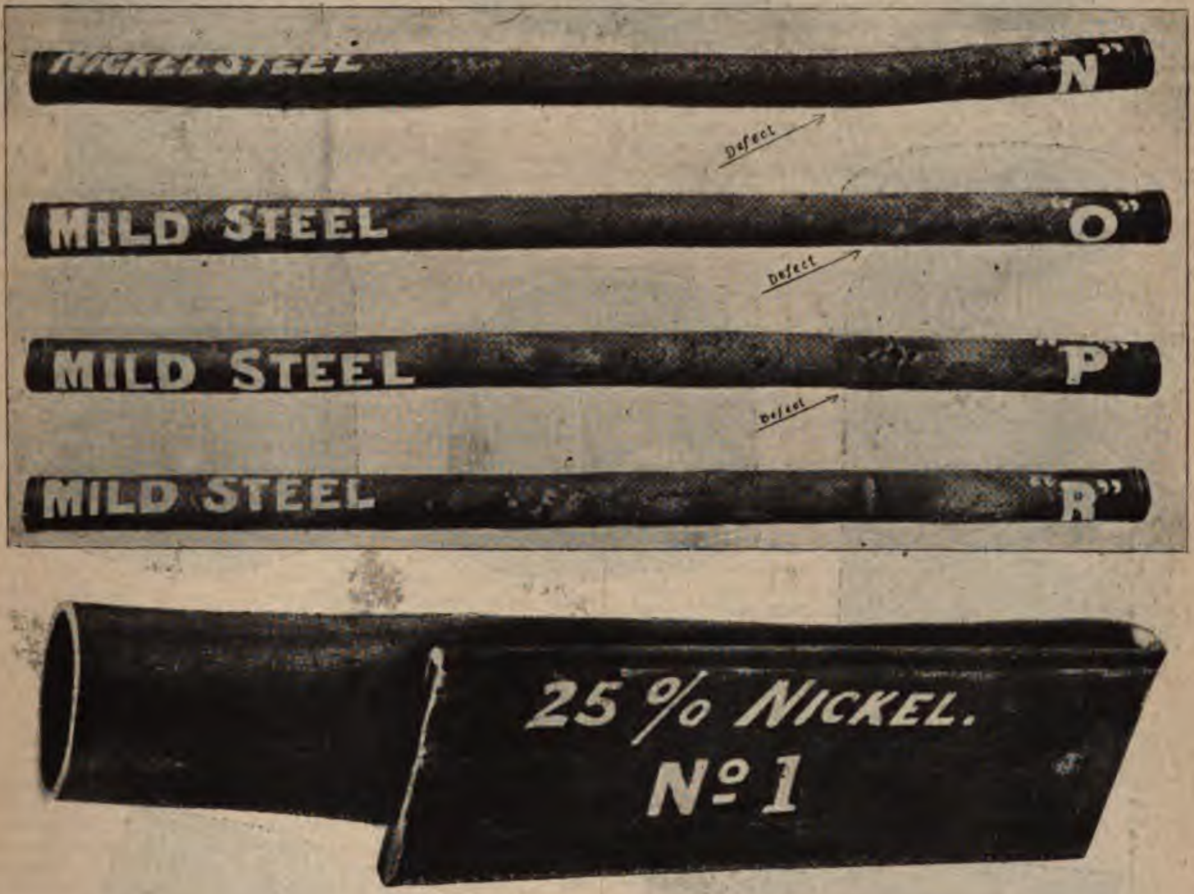

PLATE 3.

THE FLEETS OF THE MAIL LINES.

(From our own Correspondent.)

I MUST begin with answers to two kind correspondents. In the first place with regard to the gentleman from Cheshire who reminds me of the promise of a memoir of the

"Alaska,"

I would tell him that pressure on my space makes me hold it over for the present. And, indeed, the useful life of the good ship does not yet seem entirely closed. When I last spoke of her she had just been sold to a Sheffield shipbreaker for the sum of £17,500. This looked like the end, but it is not. Messrs. Vickers, Son & Maxim, who are largely extending their works at Barrow, find great difficulty in housing their augmented staff. They are building, it is said, no less than a thousand workmen's houses on Walney Island to meet the deficiency; but building takes time, and the need for accommodation was urgent. So they have given the Sheffield shipbreaker fifteen hundred pounds profit on his bargain, and have taken the *Alaska* for use as a temporary floating home for four hundred workmen. In July the old ship left the moorings in the Gareloch, at which she has so long lain, and under her own steam proceeded to Barrow, where she enters upon her new, if less pretentious, sphere of usefulness.

My other correspondent, who dates from county Dublin, calls attention to a slip in my remarks on the

City of Dublin Steam Packet Company

in the June issue of these notes. I was wrong, as he very properly points out, in saying that Messrs. Blackwood & Gordon have built six screw-steamers for the Liverpool and Dublin service. They have built six steamers, truly enough, but the first of these was a paddler; and I must further plead guilty to the charge of having omitted to regard the presence of two modern paddlers in their fleet. About the year 1880 they bought certain screw-steamers whose work probably—amongst other circumstances—contributed to show the manager that the day of the paddler was commercially closed. But they still built the *Meath* and the *Galway* on the old principle. These two vessels, as well as the *Mayo*, which I mentioned in the note criticised, are still in their active fleet.

The P. & O. Co.'s "China."

The work of preparing this vessel for rebuilding seems lengthy. There has been considerable difficulty experienced in getting away all the temporary work so well put into her at Perim. High explosives have had to be called into requisition, and at one blast a mass, estimated at 700 tons, of concrete and steel was dislodged. What the expense entailed may be, and

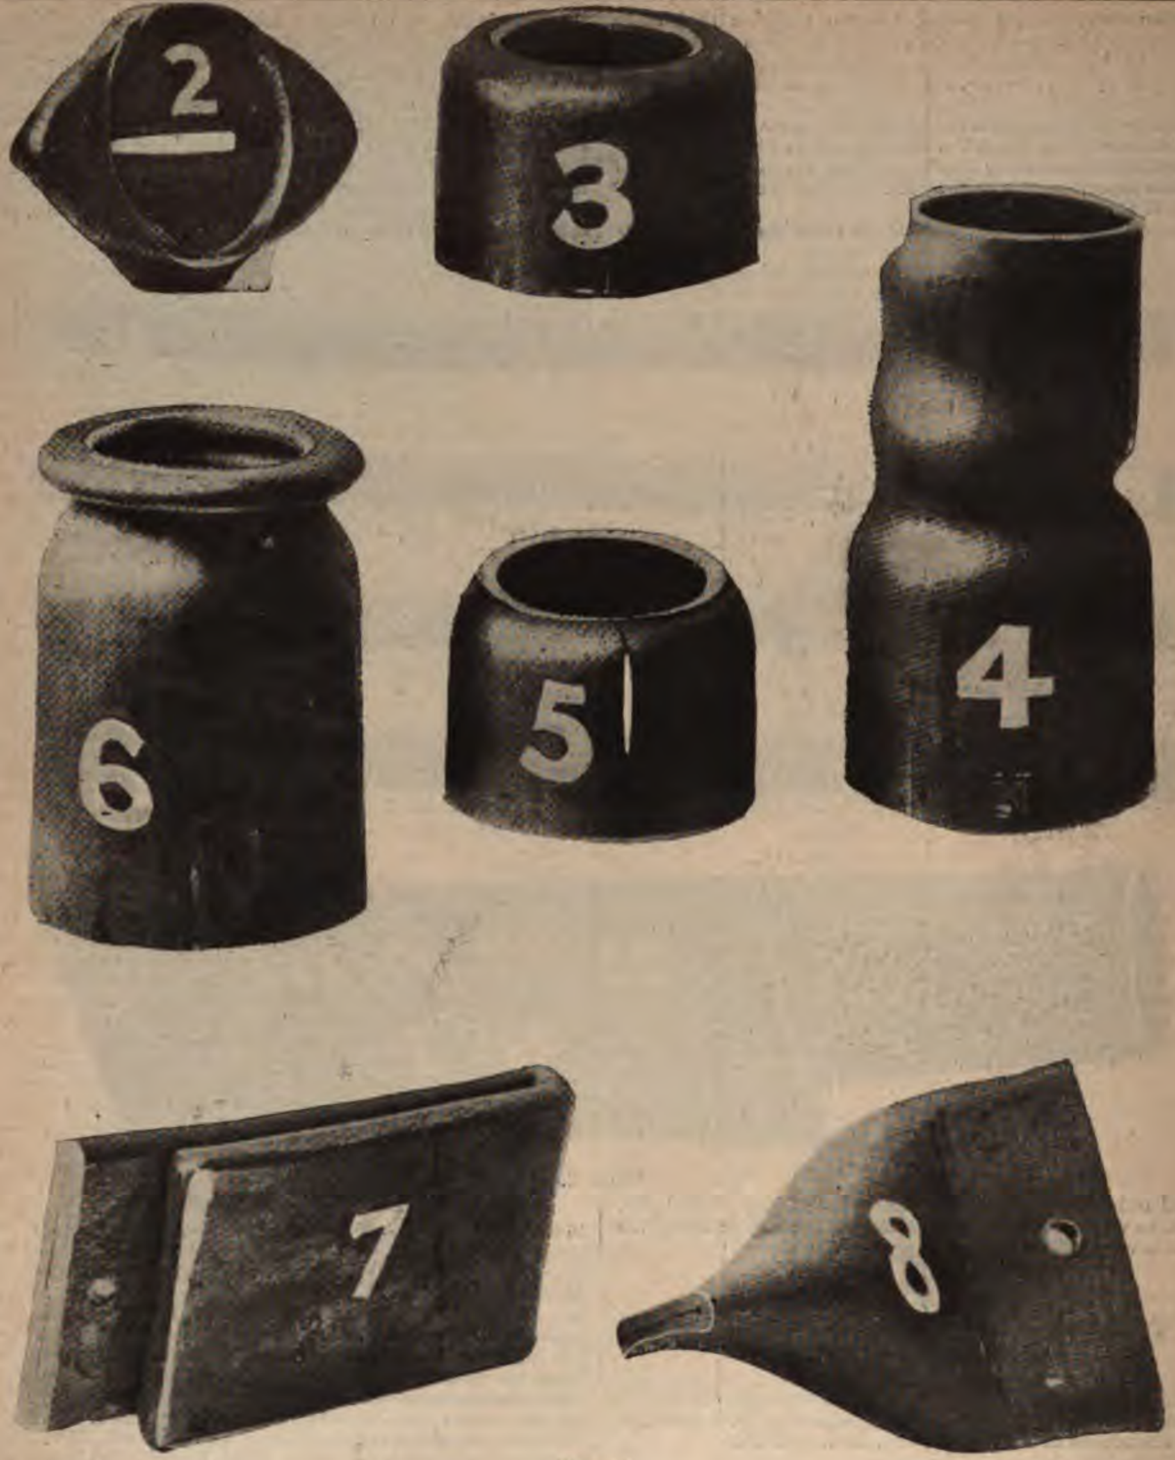

Plate 4.

Some Experiments having Reference to the Durability of Water-Tube Boilers.

how much of the original structure may remain to be worked into the new ship that is to take her name and place in the P. & O. fleet, my readers can imagine for themselves. They are never likely to know it officially, nor are they likely to know what Messrs. Harland & Wolff's bill for repairs will be; for, by a stroke of genius worthy of the mind which directs this fleet's concerns, it has been determined that whilst in Messrs. Harland & Wolff's hands the ship shall be lengthened by an additional 50 ft. Thus her carrying power will be largely increased, the shareholders will have a better earning machine than they had before, and at the same time it will be impossible in the big bill which will have to be liquidated to disentangle the charges due to repairs from those which should very properly be put down to new construction.

The "Stella" Disaster

The London and South Western Railway are about to replace the unfortunate *Stella* with a steamship of the type of their most recent acquisition, the *Vera*. This means that she will be of the twin-screw triple-expansion type, like the vessels in the Havre service and most of those plying to the Channel Islands. The difference in the vessels chiefly consists in the arrangement of their passenger accommodation. The more recent vessel is the spare boat for both services, and she is therefore now engaged in filling the *Stella's* place. She is characterised by the fact that her accommodation is arranged for running either on a day or a night service.

Southampton v. Liverpool.

In the last notes I referred to the first of Mr. Smalley's articles in the *Times* on Transatlantic liners. Since I wrote the second of these has appeared: in it he shows how the advantages which Southampton gains by her proximity to London are sacrificed by the utter want of management at Waterloo Station. Anyone who visits Waterloo Station will appreciate this comment.

The New "Oceanic."

Mr. Smalley, however, in the article in question, made one misstatement which served a useful purpose. For he said that Mr. Ismay had found out that the public craving for excessive speed in Atlantic mail steamers was greater than that experienced shipowner had imagined, that in consequence the *Oceanic* was having more boiler power placed in her. This would have been ill-bearing indeed, for it would have meant that the *Oceanic* was foredoomed to failure. Ships which are altered from their original design never succeed. Experience has shown us that. But our fears—if we ever believed what we read on this head—were speedily put to rest by a letter from Mr. Ismay himself in which he—and he ought to know as much about his own ship's internal economy even as the *Times* detailer of New York society functions—denied most emphatically that the first design had ever been in any way tampered with.

A Big Deal

has been effected in the sale by the New Zealand Shipping Company of its four more purely mail and passenger steamers. It may be remembered that when this company first went into steam it chartered a number of steamships belonging to other lines. These included certain White Star boats. Then it constructed five steamers of its own, and with them maintained for many years a regular four-weekly service between London and New Zealand ports. The five vessels in question were the *Aorangi*, *Tongariro*, *Ruapehu*, *Kaikoura*, and *Rimutaka*, which were built in the order named. All came from the famous yard of John Elder & Company, of Fairfield. These were all barque-rigged screws, well able to use their canvas in aid of their steaming powers. They came out in the years 1883 and 1884. The first three were 389 ft. long and just under 4,200 tons gross register. The latter pair were about 40 ft. longer, and of about 300 tons greater tonnage, than their earlier sisters. All had compound engines. Changes have come over the trade since those days, and vessels of a very different class have taken their place. The new comers are slower, larger, and cheaper to run, whilst they have much greater refrigerating installations. So the older boats have found their places filled. The *Aorangi* was parted with some time ago. Re-engined and boilered, she joined the Huddart Line between Sydney and Vancouver. This I incidentally referred to in last month's Notes. The *Tongariro* and the *Ruapehu* have been recently running in the Beaver Line (Associated Steamers) under the management of the Messrs. MacIver, of Liverpool. Before she entered on that service the last-named distinguished herself by the feat of towing out the huge floating dock—built for the Spanish Government by Messrs. C. S. Swan & Hunter—from the Tyne to Havannah. The whole are reported to have been bought by British buyers, who are stated to be the British India Steam Navigation Company, Limited, at a price of about £75,000. As the ships aggregate about 17,300 tons, the price is something over £4 a ton for 16-year old vessels.

The Hamburg-American Line

has made a new departure for foreign liners. They have announced that they have adopted the precautions of having a deep-load line. The German Emperor has signified his pleasure and satisfaction at the move. But personally, in the absence of further information, I fail to see exactly where the benefit comes in. We are not told on what principle the marking is to be ascertained. Until we have some explanation of the rules which shall guide those who are to fix it, it would appear to be a very unnecessary precaution. There is no magic in a load-line, nor in a disc by itself. The only value comes when it is affixed under rules which enforce that it shall be so placed as to give the ship ample reserve buoyancy, and when there is authority behind those who fix it to take care that under no circumstances shall the draught it allows be exceeded. A voluntary load line may be quite a negative blessing.

A far more promising innovation is that which has been announced by

The Atlantic Transport Company.

Profiting by the loss of the *Mohegan*, whose end is attributed to an error in judgment, such as those to which other captains and other human beings in general are liable, it has taken the best means in its power to avoid the possibility of the recurrence of such a failure. An order has been issued from the office to each master in its employment enjoining that in future the ship's course is to be set by the junior officer of the watch. All their ships carry two deck officers at all times, and so the work of the junior can hardly escape the criticism and, if need be, the revision of his superior. Above both comes in the master, who doubtless will be only too glad to show occasionally that his officers are not yet quite perfect in their navigation. So under the new system three people ought to be at fault before an error can have fatal results. Possibly it may be said that the same could have been urged of the old system. This may be true. But no one with any knowledge of methods at sea, and of the discipline there observed, can suppose that juniors could have been as quick to criticise the work of the commander himself as the latter must be to check the work of those under him.

La Bourgogne.

I had hoped, as I said last month, that we had done with this sad story. But it has cropped up again. This time it is before the French courts, where the widow of a passenger has been awarded £4,000 for the loss of her husband through the disaster, which, as the French courts now decide, was due to the fault—at least, in some measure—of the company's servants. This judgment looks at first sight to be a very severe blow to the company, especially as we hear from similar sources that a very large number of actions hang on that which we are discussing. But there is a reservation in the case which has not attracted much notice. It is, however, likely to prevent the widow from reaping any very tangible satisfaction from her legal victory. The award is "subject to the option of the company to renounce all rights over the vessel and her cargo." They are not likely to think twice about the matter. The vessel lies in the bed of the Atlantic. Her cargo is with her, and the chance of any salvage is remote and shadowy indeed. *Per contra* the claims in respect of her loss are very solid and immediate, and there can be little doubt of the course which the company will take. If this is French maritime law—and there is no doubt that it is—the conference which is now sitting with a view to induce this country to assimilate its jurisprudence in maritime affairs to that of the Continent is not likely to meet with much success. A worse illustration could hardly have been put forward.

The Norddeutscher Lloyd

is very unfortunate with its new fleet of express steamers for the New York service. The *Kaiser Wilhelm der Grosse* indeed has proved herself a magnificent success. She is deservedly popular with the travelling public, and has just broken her own record eastwards by running to Cherbourg at the fine speed of 22·61 knots. The *Kaiser Friedrich*, built to be her equal in speed with a 20 per cent. saving in displacement, has, however, not yet achieved contract speed, and accordingly has, after about a year's trial on the station, been withdrawn from the service and returned to her builders. Doubtless we shall yet see her doing what was promised of her. But it is hard on the company that they should have been deprived of her services during the present passenger season, when all the Americans who were kept at home last year by the war are coming across to make up for lost time.

The *Kaiserin Maria Theresa*, too, has had bad luck. She was completed in due course, and was advertised to take the outward sailing of the 14th June. But on her way round from Stettin she went ashore, and for a time resisted all the efforts that half-a-dozen powerful tugs could put forth. She came off at last, and on the 26th June reached Stettin for repairs.

The Isle of Man Competition.

On July 1st, according to promise, the new Isle of Man Company started its daily excursion service from Liverpool to Douglas with the ex-Royal Mail steamship *Ireland*. The old company detailed their *Queen Victoria* to run against her, and the return fares for the excursion were reduced to 4s. first and 2s. 6d. second class. The *Ireland* did not do well on this day. Her time for the round trip was as much as eleven hours, against just under six hours by her rival. The practice with the *Ireland* was a good deal better on the Monday and Tuesday of the following week. But on the Wednesday the new adventure made its last sailing for the time being—the management announcing that the withdrawal was only temporary, and that further sailings would be announced. It would appear that the failure of the *Ireland* to do anything approaching her normal speed was due to trouble with her feed pumps. It is promised that this shall be remedied. The old company's service should really satisfy the most exacting public, for though the 20-knot *Queen Victoria* was only offered to them at these excursion rates on account of the opposition, and was not continued to them after that opposition ceased, they still had the still faster *Empress Queen*, which on July 4th exceeded a speed of 22½ knots on the Liverpool-ward run, working every day in the regular services. A table of the performances of the three vessels named has been published, but I do not think it of sufficient public interest to warrant my reproducing it. It may, however, be worth remarking that the *Queen Victoria* herself, with her sister ship the *Prince of Wales*, came into the possession of her present owners through a similar competition to that now existing. The two steamers in question were built at Fairfield for an opposition line to the Isle of Man, and were bought out and taken over by the old-established line.

New Companies.

During the month of July the old-established shipbuilding and engineering firm of Wigham, Richardson & Co. has taken advantage of the limited liability Acts, comingout with an issue of £220,000 in ordinary and preference shares. The object of the change is stated as preliminary to an extension of the enterprise. It appears from the prospectus that the concern dates as a shipbuilding yard from 1860, the engine and boiler shops having been added twenty-one years later. At present the output is nearly thirty thousand tons of steel shipping per annum, whilst the engines turned out in the year indicate about 80,000 H.P. There are about two thousand hands employed.

The Anchor Line followed the same course a week later. Its capital amounts to £575,000, in preference and ordinary shares, with £325,000 debentures. Of the share capital only the preference, amounting to a quarter of a million sterling, were offered for subscription, the partners in the old firm of Henderson Brothers taking all the ordinary. The fleet is stated to comprise twenty-two vessels aggregating 79,742 tons, whose value is stated by the certificate of Messrs. Kellocks to be £535,000. But the company does not own quite the whole of the fleet, one-sixth per cent. interest in it is stated to be "held by large and influential supporters of the line." On the other hand, the fleet is by no means the only asset. There are interests in the shipbuilding and engineering business of Messrs. D. & W. Henderson, of Glasgow, in the Barrow Steamship Company, and in the Ship-Chandlery and Sailwork Company of Glasgow. Details of what is comprised herein are not afforded, but we are told that they are worth another £160,000.

Southampton

is said to be handicapped by the fact that it has no graving dock of what are now the ordinary dimensions for big steamships save its Prince of Wales's Dock. This, of course, will accommodate the biggest steamships afloat. But when this is occupied there is no power to deal with casualities to large vessels. A dock of some 700 ft. is now projected, and its addition to the facilities of the port will certainly make them capable of dealing with any calls likely to be made upon them in the direction of dry-docking, at least for some time to come.

The American Line

omitted its sailing from Southampton on Saturday, the 15th July. This was done to enable the *St. Louis* to take a three weeks' rest in dock, where the Clydebank workmen will fit her with the bilge keels which have proved themselves so effective in the case of the *St. Paul*. The line has of course been deprived of its reserve ship by the unfortunate catastrophe to the *Paris*. But, nevertheless, it hopes, with the three remaining ships, to fill all its mail dates till the close of the year.

The Paris,

to the surprise and delight of the salvors, who were, I think, beginning to despair, came off unexpectedly at 8.30 p.m. on the 11th July. She did so whilst the salvage boats, unaided by tugs, were attempting to slew her into a more convenient position. She was immediately made fast in the immediate neighbourhood of the place where she had been fixed for some seven weeks. There tightening and pumping were resorted to, till at length some of her own steam could be used in aid of her salvors. On the night of the 12th she was towed towards Falmouth, and by 7.30 a.m. on the morning of the 13th was safely brought into the inner harbour there and safely stowed, though with a heavy list to port.

Meanwhile her unfortunate commander, who took to himself the whole blame for the accident, has been suspended for two years by the American authorities who investigated the case. His explanation was that on the night when he left Cherbourg on the fatal trip, Cape La Hague was abeam at 6.38 p.m., and at 7.35 the Casquets were in the same relative position. The former point being 131 miles from the Lizard, he reckoned six hours and 54 minutes as the time for the run to that point, but unfortunately he took 7.35 instead of 6.28 as the time of his passing Cape La Hague. Thus he overran his distance by 18 miles. The detection of his mistake, was he says, prevented by the thick weather, which obscured the Lizard lights. The inspectors who reported on the case to the United States authorities, however, insist that the fact of the distance being overrun was not the only thing which contributed to the disaster. He was also seven miles to the northward of his course, and that, they say, must be due to a failure on his part to make any allowance for the flood tide which was running. For these failures and for non-use of the lead, this very heavy punishment is meted out to him. It is sad to think that this has befallen a man who did well indeed for the old Inman Company during a long series of years, and who earned national thanks and high naval rank for his conduct in the recent Hispano-American War. Especially unfortunate is it when it is noted that this was to be his last season's work before retirement. The case is one, however, of which the repetition seems to be provided against by the precautions which (as mentioned in an earlier note) are being insisted upon by the Atlantic Transport Company. It is simply a case of the failure of the human element—a thing that must always happen occasionally even with the most zealous and capable officers. The results of such failures are always disastrous in their magnitude in direct proportion to the power and weight of the man who makes the mistake. A duffer's mistake is not unexpected and may be provided for.

La Compagnie Generale Transatlantique

will now be able to make a sailing once a fortnight in its mail service with a fast twin screw-steamer, and that at once and without waiting for the completion of its new fleets. The French Government has given them permission—at least temporarily—to use the once-named *Normannia* in their mail service. She will be a worthy companion both in speed and in size to the French-built *La Touraine*. Whilst under the Spanish flag the *Normannia* was known as the *Patriota*. Now that she becomes French, she will be called *L'Acquitaine*, it being the custom of her new owners to call all their Atlantic mail steamers after provinces of France. It was a little unfortunate that, when leaving Ferrol at the beginning of July whilst still in charge of the Spanish pilot, the new acquisition of the French company should have gone ashore and sustained sufficient damage to render it advisable for her to put back to the Spanish port. This accident, though not a great matter in itself, will postpone the period when *L'Acquitaine* will be ready to enter on her new owners' service till too late for her to be of much use to them during the present passenger season.

Mr. Ismay

was, on the 20th July, presented with the freedom of the city of Belfast, he being but the second recipient of that distinction. That Belfast honoured herself by recognising the benefits which Mr. Ismay has conferred upon the city goes without saying. The interest of the White Star Line (which Mr. Ismay has created to an extent that no other line can be said to have been the produce of one master mind) is indissolubly connected with Messrs. Harland & Wolff's great shipyard and with the port and city of Belfast. Briefly put, Mr. Ismay's firm has spent

THE NEW YO
PUBLIC LIBR
OR, LENOX
N FOUNDA

seven millions on new construction in the yard, and has, with the product of Belfast industry, carried the knowledge of her skill in design and faithfulness in workmanship into every sea. The three hundred thousand tons of shipping which the White Star Line has itself taken from Belfast is by no means the measure of the advantage which the connection has done the city. When the long connection, now further cemented, began, Messrs. Harland's yard confined its attention to shipbuilding merely, and did not concern itself with passenger vessels. Now, and for many years past, the excellence of the work which it puts into hulls, machinery, and fittings has made its name a hall-mark in itself.

The details of the ceremony need not be here referred to. But there were one or two points about the matter which ought to be recorded. The casket in which the certificate of citizenship was presented to the new freeman was the gift of the working men, and it was remarked that they were so appreciative of Mr. Ismay's title to their affection that the subscription had to be kept down in order to enable all those who wished to do so to participate in the giving. In this regard—that of the relations of capital and labour—Mr. Ismay, alike for himelf and for the shipyard, had some claim to speak. Labour difficulties in his own business are unknown. Any delays that may take place in the delivery of White Star ships arise not from trouble at Queen's Island, but from the fact that difficulties elsewhere are cutting down the supplies of necessary material. The secret of Mr. Ismay's success has been that his motto has ever been, "Do as you would be done by." He has treated those who worked for him with generosity and they have responded in the same spirit. His gifts have ever been on a princely scale, and they have always been directed towards the most worthy objects, and such as were peculiarly within his own view and connected with his own work. As an employer of seamen he gave to the Aged Mariners' Fund at Liverpool. As one who had ships built at Queen's Island, where, in spite of all care, accidents must happen from time to time in the army of men employed, he lends splendid assistance to the Victoria Hospital of Belfast.

Recent Casualties.

The *Gallia* proves to have been uninjured by her sojourn on St. Lawrence mud, and the salvage claims against her have been settled for £4,000. But the Warren liner *Norseman*, which some time ago went ashore at Marblehead, and after prolonged operations was got off and taken to Boston, has been sold at the latter port to a Philadelphia shipbreaker for about 17,000 dollars. Since she changed hands there has been a fire aboard her as she lay at her anchors in Boston Harbour. The hull seems to have sustained but slight damage, though a number of staterooms were gutted.

The Gaspesia.

The fate of the crew of this vessel has been a very instructive —if very unfortunate—one. Engineers should read the letter which her late chief has sent to the Press, and pause before they ship with new companies owning old ships. I have from time to time recorded the adventures of this ancient P.S.N. boat, which the Canadian Steamship Company, Limited, had purchased for some £8,000 and renamed. How she was frozen into the ice off an "ice-free" port, and how after upwards of two month's imprisonment she was freed by the sealing steamer *Kate* and taken into St. John's, Newfoundland. There the salvors naturally claimed salvage, and were awarded a sum of £2,500 by the local Vice-Admiralty Court. The master communicated with his owners, and, it is said, no reply ever came to him. The salvors, getting no satisfaction for their claim, seized the ship, and the men, to whom no less than £2,000 in wages were then owing, were turned out into the streets of a Colonial town. This is very hard lines on them. But the law gives a priority to the claim of a salvor against the ship over that of the seamen; for it very fairly says, "if the salvor had failed to render his service there would be no ship for the seaman to claim against." The seaman has his rights against the owner as well as against the ship. Had the men who shipped aboard the *Gaspesia* made inquiries, they might have ascertained the financial position of the company which owned her, and they would not have shipped. They suffer from their want of caution. The sad experience will be of advantage to the general body of engineers and seamen if it teaches them to regard provable facts in connection with limited liability companies, and not the frothy and untrue statements concerning connections and prospects which the halfpenny London Press is only too glad to circulate, without discrimination, and let me hope, without inquiry.

Derelicts.

The neglect of the authorities to remove the numerous floating derelicts which render dangerous the passage of the Atlantic has long been a crying scandal. All kinds of absurd excuses have been advanced in palliation of the supineness of the authorities. But at last one case has been too glaring for silence to be maintained on the part of those who have the safety of the Atlantic at heart. So in the case of the waterlogged *Siddartha*, Lord Iverclyde, of Cunard's, and Mr. Ismay, of the White Star Line, at last addressed the authorities. When such men spoke the Admiralty had to act, and at once the obstruction was sought for, found, and recovered. The feasibility and the immediate pecuniary advantage of removing such dangers being proved, it may be hoped that a general clearance will be effected.

Cardiff

considers itself a progressive port. It is somewhat doubtful if outside its own borders the opinion will in future be entertained. Messrs. Ismay, Imrie & Company intended to give it direct communication with Australia by the new Australian line of whose inception I spoke in the last lot of notes. The *Medic* was to have coaled at Cardiff, and her sisters were to have followed her example. Four thousand tons of bunker coal would thus have been taken each month from the port by these vessels, and in addition there would have been the cargo facilities which the calling of such steamships at the port would have offered to shippers and consignees of meat. Cardiff did not see how it was to fulfil the very proper requirements of the line, and accordingly the whole suggestion has fallen through. This is not the action which might have been expected of an up-to-date harbour authority.

Canadian Mails.

The fast service to Canada comes not. But changes in the mail arrangements are always with us. The Allan Line, and with it the Dominion Company, are again deprived of their contract, and Messrs. Elder, Dempster & Company are now charged with the duty of carrying postal matter between England and her nearest colony. The newly engaged mail boats will leave Bristol each Monday, and call at Queenstown on the following day to embark the mails. The arrangement commenced with the sailing of the *Monterey* on July 24th. It is too soon as yet to do more than chronicle the fact of the contract. Its working must be regarded in future issues. But these constant changes, not only in contractors but in ports of departure, cannot fail to be highly prejudicial to that stability which is one of the essentials in mail service.

Cunard Engineers.

The Cunard Company has lost the services of Mr. Anderson, chief of the *Lucania*, and of Mr. Cuthbertson, chief of the *Umbria*, after 41 and 35 years' service respectively. On June 27th handsome presentations were made to each of these gentlemen, to show the appreciation in which they were held by their fellow-engineers in the Cunard fleet.

THE "SIRIUS" PULSATING PUMP.

IT is somewhat remarkable that the principle of the first steam-pumping engine evolved by Savary should still find a place in the commercial devices of the present day, more than 200 years after its inception. But such is a fact, as exemplified by the number of designs of this type of pump at present placed on the market by different manufacturers, many under fancy titles of ingenious construction. And, further, that as time goes on, improvements are made therein which have a very beneficial effect upon their efficiency.

The latest example in this direction is the Sirius pulsating pump, made by Messrs. Holden & Brooke, Limited, of the Sirius Works, West Gorton, Manchester. We illustrate this pump in the adjoining diagram, in which Fig. 1 is an external elevation of the pump, Fig. 2 a mid-vertical section of the same, Fig. 3 a transverse section on the line *a b* Fig. 2, and

Fig. 4 details views of the steam valve. In this class of pump a needless waste of steam is often caused by the hesitating and uncertain action of the steam valve and by its generally slower and less responsive movements. The steam not only passes at a time when it can do no work and is consequently wasted, but also when its presence actually retards the action of the pump. Further, in some forms of pulsating pump, either for cheapness or appearance, the pumping chambers are merged externally into one casting, separated internally by a diaphragm common to both; as now one of the chambers is alternately full of cold water while the other is full of steam, it follows there must be a very useless dissipation of heat through this diaphragm from the steam to the water.

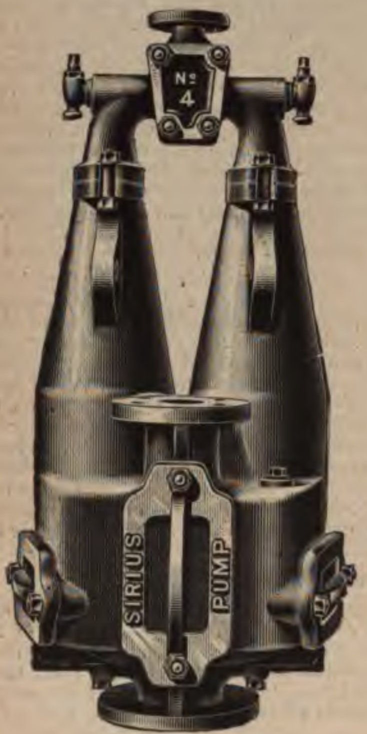

Fig. 1.

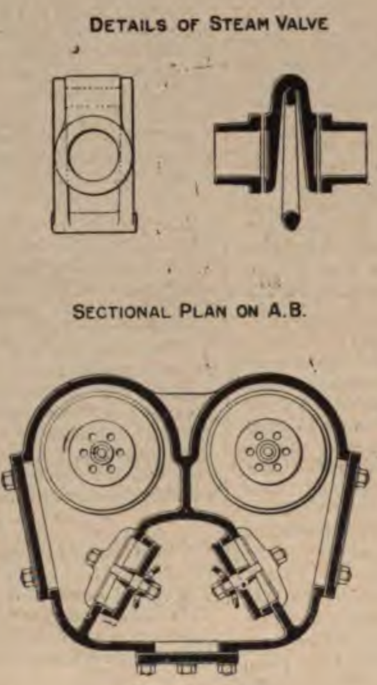

Figs 3 & 4.

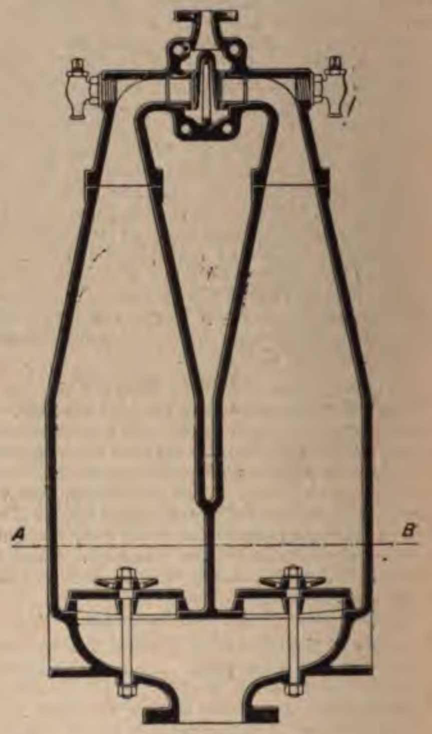

Fig. 2.

In the Sirius pump the chambers are separate and distinct, hence this useless expenditure of heat cannot take place. The chief feature, however, in the pump is the novel design of steam valve, made according to Brooke's patent, and which is clearly illustrated in Figs. 2 and 4. The manner in which this valve is hung renders it unusually sensitive and quick in its beats from side to side. On this account the heavy loss of steam at the commencement and end of each stroke before referred to is entirely avoided, and greater regularity of pulsation is secured.

Referring to Figs. 2 and 4, it will be seen that the valve is saddle-shaped, and swings freely on the top edge of a vertical plate, which, in its turn, is free also to rock on its bottom edge in a groove provided in the main casting for this purpose. The arrangement is such that it is very responsive, and swings between its two seatings with great certainty and rapidity. A further important feature of this form of valve is that its construction enables it to adapt itself to and bed dead upon its seating, owing to it being able to move freely in two directions; as in addition to swinging vertically on the plate, it can also, to a certain extent, twist sideways on it in a diagonal sense, thus enabling it to bed true on either of its seatings, even though the latter should not be parallel with each other.

The valve and vertical plate are so arranged that they cannot get out of place or touch the sides of the valve chamber, however the pump is placed. The valve is easily removed and refaced, if required, but freedom from rapid wear is provided against by the valve and seating being made of phosphor bronze and having faces of ample area. An improved form of air valve is provided, which aids to ensure greater reliability in the action of the pump, and it is claimed that in this respect the carefully designed details of the pump body generally materially assist.

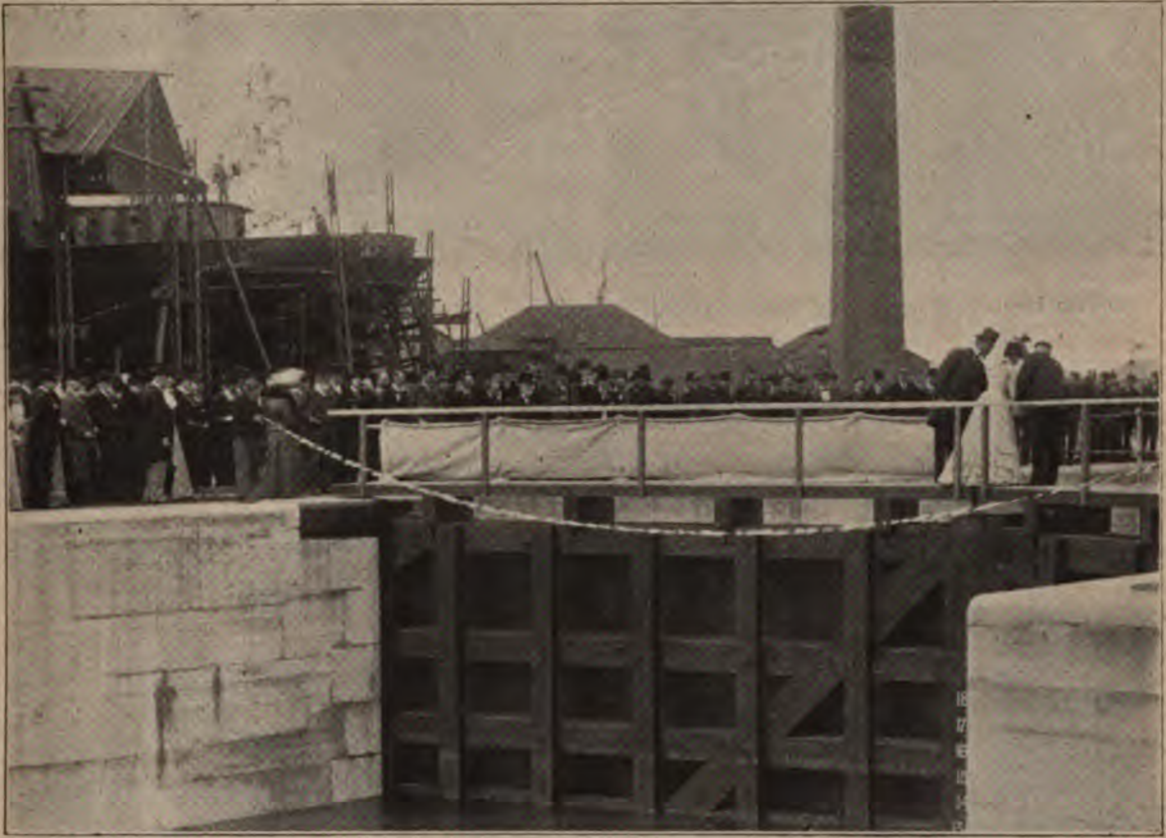
It is impossible to adequately state the many and varied purposes to which this class of pump is applicable; however, it may be stated generally that they can be employed with advantage in every industry and for every purpose in which liquids are required to be moved or raised readily, quickly, and cheaply, and where the nature of the work calls for an apparatus that demands no care or skilled attendance, but which can be relied upon to work continuously without any risk of failure or breakdown.

Inadsuma.—The Japanese torpedo-boat destroyer *Inadsuma* arrived at Yokohama on Tuesday morning, June 27th, having steamed all the way from London. This is the second boat to arrive in Japan out of the six being built by Yarrow & Co. for the Japanese Government, and is exactly similar to the *Akebono* lately tried on the Thames.

THE SHIPBUILDING AND DOCKING FACILITIES OF TROON.

TO the dry-docking facilities of the port of Troon on the Ayrshire coast—which are all practically in the hands of the Ailsa Shipbuilding Co.—a highly important accession has recently been made in the new graving dock which was ceremoniously opened by the Marchioness of Ailsa, on the 29th of June last, and is illustrated herewith. This dock, which has been under construction for about two years past, has been built at the expense of His Grace the Duke of Portland, the superior of Troon Harbour, but will, as above indicated, be leased from that nobleman by the Ailsa Shipbuilding Company—to whose yard and workshops it is immediately adjacent—and worked by them as ship-repairers in all branches.

It is interesting to recall the fact that, till about the year 1860, Troon possessed the largest dock on the Clyde, and that Glasgow, owing to shortcomings in this way, had to send her largest ships to the Ayrshire port for repairs. One of these was the steamship *Glasgow*, a crack Atlantic liner of her day. This dock was built by the fourth Duke of Portland in 1820, and, though small, as modern requirements go—being 275 ft. long, 37 ft. wide at entrance, and having a depth of water on sill at mean high tide of 10 ft.—is still in existence, in good working order, and in constant use by the Ailsa Co. Another and smaller graving dock existed for many years at Troon, but being contiguous to the site of the new dock just opened, it has been filled up, and the ground thus recovered has been added to the shipbuilding area of the yard, thus enabling the Ailsa Co., to increase their building berths to six, and otherwise improve their premises.



Opening Ceremony of the Ailsa Shipbuilding Co's New Graving Dock.

Before further referring to the vigorous and excellent work carried on by the company, and to the most recent accessions to their working facilities—thanks to the enterprise and public spirit of the noble superior, and of his able business agent, Mr. Adam Wood—a few notes reminiscent of what Troon has been as a shipbuilding and shipping locality will be interesting. The fourth Duke of Portland came into possession of the estates in 1808, and he immediately commenced the construction of the harbour. Almost concurrently a tramway was made from Kilmarnock to Troon Harbour, supposed to have been the first of its kind in Scotland. Having got the harbour made, and the tramway with wagons drawn by horses to convey coal from his own pits about Kilmarnock to Troon, he soon began to build ships in which to convey the coal to Ireland. His Grace started his shipyard at Troon, and employed as his designer and builder Mr. William Symonds—afterwards Sir Willliam Symonds—who became a man of note, and was employed in the service of the Admiralty, designing many celebrated men-of-war in his time. The coal-carrying ships were mostly of small dimensions and bore such local names as *Kilmarnock*, *Tarbolton*, *Galston*, *Dundonald*, &c., but as the "good old Duke," as he was spoken of, was also a keen yachtsman, he employed his designer's abilities in connection with yacht architecture as well. Notable amongst the productions of this class was the *Pantaloon* a 10-gun brig of 320 tons, built in 1831. This brig, in a series of trials, raced with and beat the frigates of Admiral Codrington, off the Dodman, in the same year, after which his Grace presented her to the Government, who, recognising her exceptional merits, employed her as a slave-catcher on the West Coast of Africa.

After the Duke's time the shipyard was let, and the building of vessels of wood was carried on by several firms in succession, until about 1850, when the Portland Shipbuilding Co. came into possession. Under the management of the late Mr. John Hay, this company built the *Earl of Eglington* in 1854, the largest wooden ship which up to that time had been constructed in Scotland. She was full-rigged, and was employed in the East India trade. Further on in the sixties there were built three celebrated China clippers, the *Silver Eagle*, *Fire Queen*, and *Salisbury*, for Messrs. Somer & Co., London. The *Silver Eagle* specially distinguished herself as the winner of the race from China to London, at the time when tea was all brought in sailing ships round by the Cape of Good Hope. In 1866, the shipyard went into the hands of the Troon Shipbuilding

The Full-rigged Ship "E. J. Spicer," of Nova Scotia, entering the Ailsa Shipbuilding Co.'s New Graving Dock.

Co., who continued building and repairing till 1886, after which the yard was taken over by the present company.

Concurrently with the taking over of the yard by the Ailsa Shipbuilding Co., Troon, entered on a new era in its history as a shipbuilding port, by the starting of iron shipbuilding, in which work the three active partners—besides the Marquis of Ailsa—had exceptional training and experience. These were Mr. Alexander McCreadie, Mr. Peter Wallace, and Mr. Robert Carswell, the two former having held responsible positions for a long period of years, the first as ironwork manager, and the second as chief draughtsman, in the yard of Messrs. A. & J. Ingles, of Pointhouse; and the latter, Mr. Carswell (who recently retired from the company), having held an equally important post in the commercial department in Messrs. J. & G. Thomson's, now the Clydebank Co. Under the new *regime* the construction of iron ships was soon being spiritedly carried on, the co-partnership apparently having the faculty of attracting customers, and, better still, of giving them great satisfaction in the quality and rapidity of the work produced. Extra ground was taken in, the launching berths were extended, and the necessary ironworking plant was installed, and fittingly housed. Some of the finest cargo boats, passenger steamers, and steam yachts afloat have been turned out by the company. In the two graving docks, the smallest of which has been replaced by the fine new dock which is the direct occasion of this article, a considerable amount of repairing work has been carried on, whilst from the berths the company have launched 80 vessels. They employ 600 workmen, and amongst the work presently on hand are three cargo steamers, a sailing ship, which is the largest yet undertaken at Troon, and two steam yachts.

The new graving-dock, which, taken in conjunction with the enlarged number of berths, should enable the Ailsa Co. to fully maintain their high reputation, is 360 ft. long on floor level, from heel posts of entrance gates to head of dock; 60 ft. broad at floor level; 48 ft. width of entrance, and has 16 ft. 6 in. depth of water over sill at mean high water; the floor level being 4 ft. below sill. A rudder-well 8 ft. deep is below floor level, near the dock gates. These are of timber, the principal parts being of greenheart. The dock has been cut out of the solid rock for the most part, but concrete facings have had to be put on altar courses and floor. There are eight altar courses a side, and access is chiefly provided to the floor of the dock by flights of steps on each side of the bow of dock.

The pumping machinery, which has all been supplied by Messrs. Drysdale & Co., Bon-Accord Works, Glasgow, consists of two centrifugal pumps, capable of pumping about 19,000 gallons per minute, and a leakage pump. These are driven by steam at 80 lbs. pressure, supplied from two Lancashire boilers 24 ft. long by 6 ft. 6 in. diameter. In the chamber which contains the pumps and engines are also valves which connect the new with the older graving-dock, which is situated at the other side of the range of building berths, and enable the necessary pumping operations to be conducted by the same new powerful engines, and under the control of one man. To make this possible the new was connected with the older dock by a tunnel running under the shipyard. The engines previously in use in connection with the older dock will now be utilised for driving the saw-mill plant of the Ailsa Co. On the occasion of the official opening of the dock, on the 29th June, the contents were pumped out in about two hours, the vessel first accommodated being the full-rigged ship *E. J. Spicer*, of Nova Scotia, as shown in one of our views. The contractor for the dock and gates was Mr. George Lawson, Rutherglen, and the whole of the works were carried out according to the plans, and under the superintendence of Messrs. M'Taggart, Cowan & Barker, civil engineers, Bath Street, Glasgow.

THE "STORZ" PATENT HOSE UNION.

THE characteristics of an ideal hose union are without doubt—firstly, that each half shall be exactly alike, so that it does not matter which end of the hose-pipe is coupled; secondly, that the coupling shall be, as far as possible, round, and have no projections, so that couplings cannot be held fast when the hose is pulled along uneven surfaces, and the hose be prevented from being worn more on one side than another; thirdly, that it shall be, as far as possible, instantaneous in its action, so as to save time and labour as far as possible.

In the adjoining illustration we show a very simple, efficient, and economical connection for hose-pipes of every description, which, we think, may fairly lay claim to a practical fulfilment of the conditions as set out above. Fig. 1 shows a perspective view of the two parts ready for engagement, and Fig. 2 is an external view of a hose-pipe and union connected together. Each portion of the union consists of a metal nipple on to which the hose-pipe is secured, and the end of which carries an elastic jointing-ring held in a suitable locking recess. This nipple has a shoulder, at the back of which a coupling-ring is engaged, so as to turn freely on the nipple, so that the hose can be twisted without interfering with the coupling; and, further, it avoids the necessity of twisting either end of the hose when coupling or uncoupling it. On the outer end surface of the coupling-ring two hooked projections are situated, and in the body of the ring between the hooked projections two circular recesses are provided, each having a ledge, or surface, which is obliquely situated to the plane of the ring, and adapted to engage with the two hooked projections of the corresponding part of the hose union when they are inserted therein. At the end of each circular recess an opening is made to allow of each hook entering the recess.

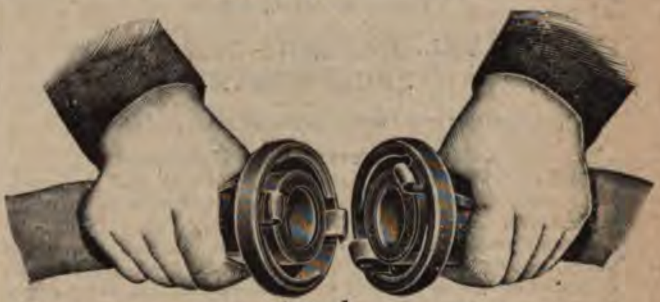

FIG. 1.

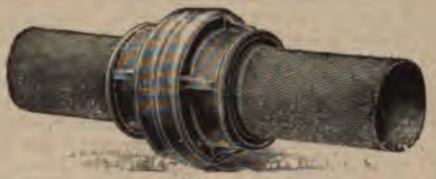

FIG. 2.

When the hooks have been entered into the respective recesses the two coupling-rings are rotated in opposite directions relative to one another, whereby the hooked ends ride up the oblique surfaces and draw the two parts of the coupling together, pressing the elastic jointing-rings into close proximity so as to make a watertight joint.

It will be generally conceded, we think, that this union is a very secure, light, and compact device, and is a most efficient substitute for the old-fashioned screw couplings. As evidence of appreciation of its merits, it may be mentioned that the unions are being used by the Imperial German Navy, the Imperial

Austrian Navy, the North German Lloyd Steamship Co., the Vulcan Co. (of Stettin), Schichau (of Danzig), Blohm & Voss (of Hamburg), Messrs. Wigham, Richardson & Co., and Messrs. Armstrong, Mitchell & Co. (of Newcastle), besides over 20 fire brigades of foreign countries.

The sole licensees of this invention for Great Britain and the Colonies are Messrs. Smith Bros. & Co., of Hyson Green Works, Nottingham.

NAVAL MATTERS—PAST AND PROSPECTIVE.

(From our own Correspondents at home and abroad.)

The Naval Manœuvres: The Mobilisation.

THE most important matter connected with the Navy this month is, of course, the partial mobilisation for the manœuvres. The mobilisation took place on the 11th of July last, the number of newly commissioned vessels hoisting the pennant being 30 cruisers, four torpedo-boat destroyers, and 24 torpedo-boats, a number of other vessels having their crews brought up to the full complement. From Portsmouth eight vessels were commissioned, their names being the *Europa*, *Andromeda*, *St. George*, *Gladiator*, *Sybille*, *Naiad*, *Latona*, and *Mercury*, and two destroyers and 10 torpedo-boats. The types represented by these ships are, as will be seen, many and varied. The *Europa* and *Andromeda* are sister ships, but the *St. George* is of another type of cruiser. The *Sybille*, *Naiad*, and *Latona* are sister vessels, and the *Mercury* is the oldest of the eight, although by no means to be despised now that she has received a fresh armament of modern guns. Eleven cruisers in all were sent out from Devonport, including the *Juno*, *Thames*, *Forth*, *Cambrian*, *Charybdis*, *Æolus*, *Retribution*, *Rainbow*, *Sirius*, and *Spartan*. Two destroyers and seven torpedo-boats also hoisted the pennant at this yard. From Chatham Dockyard 11 cruisers and seven torpedo-boats assembled to take part in the manœuvres. These included the *Argonaut*, *Vindictive*, *Minerva*, *Diana*, *Brilliant*, *Apollo*, *Andromache*, *Sappho*, *Terpsichore*, *Mersey*, and *Arethusa*. Of these ships the last-named is the slowest, as she is only able to steam at 16 knots speed, whilst the *Argonaut* is able to cut through the water at a speed of 20·5 knots. Although such a number of vessels have been commissioned, there are still a great many left at the dockyards, and the demand occasioned for men by these vessels hoisting the pennant did not, as was prophesied would be the case, leave the dockyards empty as regards seamen; as at Portsmouth for instance, after all the vessels commissioned there for the manœuvres had left, there were still some 4,000 men to spare. On the whole the machinery of the newly commissioned vessels acted very satisfactorily, although it is now two years since a partial mobilisation of the Reserve took place. Only one ship failed to be ready on the evening of the 11th of July, owing to the disablement of her steam capstan. Several of the torpedo-boats had to be put back for repairs owing to bad weather being encountered, and two of the destroyers exercising at Stokes Bay collided. But these mishaps are expected, and in fact anticipated, for spare boats and spare gear are always kept ready in case of such accidents happening.

The "General Idea."

War began the last week in July, and is to be kept up until the 5th of this month. Officially defined, the "general idea" is as follows:—"A British convey (C) of slow ships escorted by a fast cruiser, on passage from Halifax to Milford Haven, is ordered to await at a certain rendezvous the arrival of a protecting squadron. N.B.—The slow ships cannot be taken in tow, must remain in company, and have no fighting value. A hostile squadron (A) of fast ships, lying at Belfast, is sent to intercept and capture the convoy and bring it into Belfast. After an interval, a superior British squadron (B) of slower ships is sent to protect the convoy (C) which has been ordered to a prearranged rendezvous, cover it from the hostile squadron, and bring it into Milford. The whole of Ireland is hostile territory, and belongs to "A." The coast of England and Wales from the Island of Islay to the Lizard, including the Scillys and the Isle of Man, is British territory. The hostile fleet (A) has torpedo boats at Waterford, Kingstown, and Belfast. The British fleet (B) has destroyers at Milford Haven, Holyhead, and Lamlash. Generally the idea may be said to be a good one, and provided no "holes" have been left in the rules of the game which flag officers could take advantage of, and render the manœuvres fruitless, some first-class lessons in naval strategy should be gained. The advantage possessed by "B" fleet is that, although slower than "A" fleet, it is stronger, for, however fast a fleet may be by itself, it would have to accommodate itself to the speed of the slowest vessel with which it is keeping company, and therefore the capture of the convoy "C" by "A" fleet renders it slower than "B" fleet, which if it manages to come up with the enemy in charge of the captured convoy, should make good use of its superior strength.

The Objects of the Manœuvres.

The principal object, we are told, of the manœuvres this year is to obtain information as to the most advantageous method of employing a considerable body of cruisers in conjunction with a fleet. A subsidiary object is to throw some light on the relative advantages and disadvantages of speed and fighting strength. Another subsidiary object is to obtain information relative to the working of destroyers and torpedo-boats. The most important lessons learnt from the above will be in connection with systematic scouting, for which such a great number of cruisers have been commissioned. Attempts have been made in former years to throw some light upon this question, but that very little was learned will be seen when the failure of the American scouts, who were sent to look out for Cervera's squadron, is recalled to mind. A great deal of interest, too, centres in the operations of the torpedo craft. These vessels will, no doubt, have to perform a good deal of hard work before the war is finished, and the provision of so many spare boats ready for sea shows that doubts are felt as to how these delicate vessels will stand this hard work. The employment of destroyers as torpedo-boats in the manner indicated in the "general idea" should give us a practical demonstration of their value, and settle the discussion raised some time since as to the advent of the torpedo-boat destroyer sounding the death knell of the battleship. Up to now the machinery of the newly commissioned vessels has given little trouble, or at any rate, the engineer officers have managed to keep the vessels going. Fleet "A" is commanded by Vice-Admiral Sir Harry Rawson, and consists of eight battleships, three first-class, 14 second-class, and two third-class cruisers, with 28 torpedo-boat destroyers and three gunboats. Fleet "B" is commanded by Vice-Admiral Sir Compton Domvile, who has under his command 10 battleships, four first-class and 16 second-class cruisers, in addition to 24 torpedo-boats and three gun-boats. He has also, of course, the convoy of two slow vessels under his charge.

Portsmouth Dockyard.

The departure of the ships which were made ready at this yard to take part in the manœuvres did not make much difference in the amount of work usually carried on. The repairing basin was cleared out, with the exception of the gunboat *Excellent*, and at the depot and in the gunnery and torpedo schools there were, of course, fewer hands. But there are still 4,000 men at work or at drill in the depot and gunnery and torpedo schools. Further reports are to hand of the failure of the patent fuel experimented with in the *Surly*, and one result, which ought to be enquired into, is that some of the men who were assisting in the discharge of the last cargo of compressed coal-dust briquettes have had their eyes affected by the work. The trials of the battleship *Canopus* will probably take place early this month, but if they are postponed, as has been done several times previously, no surprise will be felt. The cause of the delay is that the engines of the *Canopus* are not yet ready. Very little progress is being made with the new Naval Barracks. At least, this is the impression conveyed to an outsider. Some 500 men have been at work pulling down the old buildings, and when the tons of brick and rubbish have been cleared away, the work of building the new barracks will be commenced. The *Narcissus* lies in the steam basin here ready for overhaul. Her refit, which is not to be taken in hand just yet, is estimated to cost about £20,000.

Two New Warships Launched.

On the 25th ult. the first-class battleship *Vengeance* took the water, her launch being carried out in the successful manner characteristic of the firm of Vickers, Son & Maxim, where she was built. The *Vengeance* is to have a displacement of 12,950 tons, and is built almost entirely of steel. Her length is 390 ft., beam 74 ft., with a draught of 26 ft. She is to cost £814,619. The armament of the new battleship is to be four 12-in., twelve 6-in. quick-firing, and twelve 12-pounders. She is to have a complement of 750 officers and men, and is to be able to steam at 18·25 knots under natural draught. The cruiser *Pioneer* was successfully floated out of dock at Chatham earlier in the month. The christening ceremony was performed by Miss Andoe, daughter of the admiral-superintendent of the yard. The *Pioneer* was begun on December 16th, 1897, and the weight of the vessel at the float-out was 1,500 tons. The *Pioneer* is a sister to the *Pelorus*, and has the following characteristics:—Length between perpendiculars, 305 ft.; breadth extreme, 37 ft.; draught of water, forward, 12 ft.; aft, 15 ft.; displacement, 2,215 tons. She is to be fitted with four-cylinder inverted, vertical triple-expansion engines and eight boilers of the Thornycroft water-tube type. The I.H.P. is to be 7,000, and the speed anticipated with this power is 20 knots. She will have a coal storage at normal draught of 540 tons, and carry 224 officers and men. Her armament is to consist of eight 4-in. quick-firing, with eight 3-pounder Hotchkisses and 3·45-in. Maxims.

Novel Methods of Ship Communication.

Public as well as professional interest has been roused by the statement that the *Juno*, one of the vessels taking part in the mimic fighting now in progress, is supplied with a special Marconi apparatus for the purpose of receiving and sending telegraph messages without the aid of wires. For several years past the torpedo officers of the Navy have been experimenting in wireless telegraphy, and Captain H. B. Jackson, of the torpedo school-ship *Defiance*, has invented a system which is at all events equal, and probably superior, to that of Signor Marconi. It was therefore amusing to be told by some of the daily papers that Commander Nicholson, of the same ship, had "mastered the principles" of wireless telegraphy, and had therefore been selected by the Admiralty to embark in the *Juno* for the purpose of watching the experiments with the Marconi system and reporting upon them. The reason that the Admiralty has not been as keen in taking up Marconi's invention as the French naval authorities is probably because it has some faith in the efficiency of Captain Jackson's idea. Another novel method of communication between ship and shore is the use that is to be made of carrier pigeons. The birds are to be used chiefly in connection with the torpedo flotilla exercises, as it is evident that they would not be of much use as a means of communication between the cruisers and the fleets for which they are scouting, for it is not likely that the birds would reach home if liberated more than a couple of hundred miles from shore.

Devonport Dockyard.

The fact that Plymouth has been made the headquarters of the torpedo-boat flotilla during the Naval Manœuvres has afforded visitors to this place an interesting sight and one not often witnessed. Captain Hamilton certainly deserves praise for the great amount of trouble he took to make his fleet efficient. Several of the boats developed slight machinery defects, but every case was attended to in less than 12 hours, and this, it must be admitted, reflects some credit on the engineering staff at this yard, and more especially, as with the exception of three, all the boats are about 15 years old. An order has been received at Keyham Factory for the manufacture of boiler tubes for the torpedo-boat destroyers *Fame* and *Whiting* on the China station, and the *Foam* on the Mediterranean station. The Admiralty in this manner show that they appreciate the work previously done at Keyham in this direction. It is worthy of mention here that probably at the end of this month the *Fervent* and *Zephyr*, a couple of torpedo-boat destroyers ordered from Messrs. Hanna, Donald, & Wilson, at Paisley five years ago, will be delivered at this yard. It will be remembered that they failed to obtain the guaranteed speed on trial, and have had to be reboilered. Their maximum speed is to be 27 knots. The preliminary trials with the boats have proved successful, and there is little doubt that the official trials on the Clyde will turn out equally so. The *Implacable* and *Bulwark*, now in course of construction here, are to be fitted with as much non-inflammable wood as possible. The cabin doors and bulkheads are to be made of the new wood, and now that the Admiralty have decided to use it in these vessels, it is probable that in future new ships will have a large number of their permanent fittings, which are now made of steel, constructed of non-inflammable wood. Considerable satisfaction has been expressed with the result of the trials of the *Highflyer*, and although the *Hermes* rendered such a good account of herself as regards her steaming powers, the *Highflyer* has beaten her.

The Royal Dockyards Reorganisation Scheme.

The advantages anticipated by the new scheme of organisation sanctioned by the Admiralty in reply to the dockyard subordinate officers' petitions simplifies matters all round, both as regards officers and men. The wages to be paid for definite work done at the yards is made clear, and it will now be practicable to modify the scheme rates from time to time as experience, improved methods, &c., may necessitate. According to the new reorganisation scheme, which is to take effect from the commencement of the present financial year, the principal changes brought about will be as follow:—The three existing grades of supervising officers, viz., in the case of shipwrights, inspectors on salary, and chargemen of day pay, and, in the case of other trades, leading men and chargemen, are to be ultimately replaced by two grades—inspectors of shipwrights and of other trades and chargemen. The ultimate staff of inspectors of the several trades and their salaries are to be:—Shipwrights, £130 to £170; hydraulic work, £130 to £170; joiners, £110 to £150; ship and electrical fitters, £130 to £170; plumbers, £105 to £115; painters, £100 to £130; caulkers (wood), £110 to £140; engine fitters, £130 to £170; boiler makers, £130 to £170; boiler makers (Sheerness, charge pay in addition), £30; coppersmiths, £130 to £170; founders and pattern makers, £130 to £170. The existing inspectors of shipwrights who have been three years at the maximum of the present scale, and who are appointed under the new scale, are to be granted an immediate increment on that scale, whilst the salaries of those who have been recommended for the new class, but are now drawing less than the new minimum, will be raised to that minimum. The men will now be able to see exactly how much they earn according to the work they do. Previously this was not the case, and there was consequent discontent on the part of those who could not follow the old schemes.

Smart Coaling Feats.

The evolution of coaling ships always calls forth a good deal of competition, and during the month some exceptionally smart performances have been made by some of the ships of the Channel Squadron. The most noteworthy is that of the *Diadem*, which a couple of weeks ago eclipsed all her own previous records, and almost beat the record made by the *Majestic* at the beginning of the month. The *Diadem* had 1,500 tons of coal to take on board, and managed to complete the task in five minutes less than 15 hours, making an average of something over 100 tons an hour. Coaling was commenced at five o'clock in the morning, and although some delay was experienced, owing to the continual breaking down of the steam winches of the collier alongside, the operation was finished by 9.15 p m. the same day. Out of this time one hour and twenty minutes was taken up for meals. The Admiral at the Nore complimented the *Diadem* on her smart feat. Earlier in the month the *Majestic* took in 1,300 tons of coal in ten minutes under fifteen hours. The same ship had previously coaled at the rate of 161 and 172 tons an hour, but for so large a quantity, and having regard to the fact that the coal was shipped on one side only, the performance surpassed any previous record, Apparently, the ships of the Mediterranean Squadron are not so smart at the work, for the result of a coaling operation at Marmarice, in which all the battleships took part, was that the average amount of coal taken on board per hour ranged from 110 to 27 tons. However, little comparison can be made in this case, as the ships took in coal from the colliers, and the first ships to coal had, of course, an advantage over those that cleared the colliers.

Chatham Dockyard.

The 18 vessels commissioned here for the manœuvres were made ready for sea without the least confusion, although the yard generally presented a busy scene. After the manœuvres are over it is expected that the *Argonaut* will be commissioned for service in the Channel Squadron, and the *Minerva* for service on the China station. The completion of the *Irresistible* is being pushed forward as rapidly as possible. She has received a great number of her armour plates, and if the contractors had been able to supply the armour plates at the proper time, every one would by this time have been in position. Messrs. Maudsley, Son and Field, the engine contractors, have now forwarded the remainder of the machinery required to complete the main engines. Special efforts are to be made to have the *Irresistible* ready for her steam trials early next month, and she will probably hoist the pennant in the commencement of the third month of next year. The steam trials of the *Coquette*, it may be mentioned here, did not prove as satisfactory as could be wished for, as she failed to realise the contract speed. She has undergone certain structural alterations in her boilers after having been returned to the contractors. The steam trials of the *Albatross*, *Mermaid*, and *Cheerful* are also to be carried out whilst the Reserve is away for the manœuvres. It is probable, too, that the steam trials of the *Goliath* will be carried out very early this month, if a crew can be got together for her. Her gun mountings are now almost completed, and she is only waiting for Messrs. Vickers, Sons and Maxim to deliver the gun shields. However, if these have not arrived at the time she is ready for sea, she will probably carry out the trials without them. Good progress is being made with the *Venerable*, which was laid down at the commencement of January last, and preparations are being made for the reception of the main-engine shafts. She will probably take the water in October.

The Failure of Oil Fuel.

It is to be hoped that the failure of the oil-fuel trials in the *Surly* will not cause the Admiralty to completely abandon the experiments, although it must be admitted that the task of bringing this fuel into practical use seems well-nigh hopeless, at any rate with the furnaces which are used on the *Surly*. The thick black smoke which pours out of the funnels of this vessel when the trials are in progress has not been noted in recent experimental trials abroad, and as a matter of fact, in Italy, France, Russia, and the United States, one of the chief advantages claimed for oil fuel is its smokelessness. The new ships of the Russian Black Sea fleet can burn either oil fuel or coal, and the same is the case with the *Sardegna*, *Sicilia*, and many other vessels of the Italian Navy. The Admiralty might do worse than take a hint from the Russians or Italians as to the proper way to burn oil fuel in warships.

The Trials of the "Prometheus."

The monotonous regularity with which cruisers built at the private yards successfully passed through their trials has not been broken in the case of the cruiser *Prometheus* recently delivered at Sheerness from the works of Earle's Shipbuilding & Engineering Co., Hull. The only hitch that occurred in the whole of the trials was during the gun-mounting tests. Orders were given for the anchors to be lowered; and, subsequently, when the capstan lifted the port anchor some links of the cable belonging to the starboard anchor were found to be coiled round it. The operation of clearing the cable occupied about nine hours. The 30 hours' coal consumption trial at half-power proved thoroughly satisfactory, the coal consumption being 2·01 lbs. per I.H.P. per hour, with a speed of 17·5 knots. The eight hours' natural-draught trial also turned out very successful, a speed of 19·8 knots being obtained, and the same may be said of the four hours' forced-draught trial, at which a speed of 20·8 knots was obtained. The cruiser *Highflier* also came out of a series of trials, to which she was subjected early last month, with flying colours.

Sheerness Dockyard.

The gunnery classes here have been stopped whilst the Naval Manœuvres are in progress, as it is not possible to carry them on, so many officers and men being away in the ships which have been commissioned to take part in the partial mobilisation. Vice-Admiral Sir Nathaniel Bowden Smith has now hoisted his flag as Port-Admiral at this yard, and as he has the reputation of being a "popular" man, it is, of course, probable that he will be well liked. The *Prometheus* and *Perseus* are now being prepared for the pennant, for which they will be ready some time next month. A fair amount of work is being put into the two new sloops building here, the *Vestal* and *Sheerwater*, laid down on the 1st of February last. These vessels are to be ready for launching at the end of the year, and orders were recently received directing overtime to be worked upon them. The shipwrights at work on the sister ships, *Condor* and *Rosario*, have also been put on overtime. When the *Vestal* and *Sheerwater* take the water two new ships, larger, but of a lighter draught, will be commenced. The dockyard reorganisation scheme put forward by the Admiralty has been received on the whole very favourably. In the opinion of some it is but a weak arrangement, but others consider that if overtime be not so plentiful in the future as it has been in the past, the subordinate dockyard officers will benefit very considerably by the arrangement.

Contractors' Penalties.

In the report just issued by the Public Accounts Committee, some strong remarks are made on the enforcement of penalties on contractors for serious delay in the delivery of work done for the Admiralty. A few months ago cases were pointed out where, if the penalties had been enforced, the Admiralty would have been richer by some thousands of pounds, but then it must be borne in mind that it is not always the fault of the shipbuilder that ships are delayed in delivery. Strikes and the impossibility of turning out a sufficient quantity of armour, made according to the Admiralty's liking, have much to do with it. The contractors are no doubt as anxious to fulfil their agreements as the members of the Public Accounts Committee are to keep them to those agreements. The report points out the cases of four torpedo-boat destroyers, in which the contracts provided for penalties for late delivery at the rate of £15 a day, and that up to March 31st, 1898, delays in delivery had occurred varrying from one year and three months to one year and ten months. These penalties, if enforced, would have easily wiped off the balance of purchase money which had not yet been paid, and which amounted to £33,000. The Admiralty waived the penalties, however, and the committee, although they do not at present express any definite opinion, consider that the Comptroller and Auditor-General should be in a position to report fully on all penalties incurred by, and the penalties waived in favour of, the several contractors.

The United States Navy.

So fast are ships being completed and commissioned for the United States Navy that a difficulty is now being experienced in obtaining a sufficient number of officers for them, and consequently several ships have had to be laid up which are really wanted for service. A number of vessels, including torpedo-boats and destroyers, are now approaching completion, and it is expected that in order to get officers for them the number serving afloat on each ship will have to be reduced. The new law regarding the pay of officers came into force on the 1st of last month, and up to the present no dissatisfaction has been expressed against it. The following table compares the pay received by line officers of the Navy prior to the passage of the Personnel Bill, and that which they will receive after July 1st of the present year, when the Army pay table takes effect. In all cases the retired pay is based on the highest sea pay of the grade:—

Grade.	Old Pay. Highest Sea Pay. dols.	Old Pay. Retired Pay. dols.	New Pay. Highest Sea Pay. dols.	New Pay. Retired Pay. dols.
Rear-Admiral	6,000	4,500	7,500	5,625
Commodore	5,000	3,750	5,500	4,125
Captain	4,500	3,375	4,500	3,375
Commander	3,500	2,625	4,000	3,000
Lieut-Commander	3,000	2,250	3,500	2,625
Lieutenant	2,600	1,950	2,520	1,890
Lieutenant (J.G.)	1,800	1,350	2,100	1,575
Ensign	1,400	1,050	1,960	1,470

A piece of news which will interest engineer officers on this side of the Atlantic is the fact that all vessels of the United States Navy hereafter shall be equipped with boilers of the tubular type. It has been recommended by Rear-Admiral Melville that the battlehips *Maine*, *Missouri*, and *Ohio* shall be constructed under plans that require these boilers, and the armoured cruisers and unprotected cruisers authorised last session shall also be similarly equipped. It is the opinion of Admiral Melville that experience justifies the Department in applying generally this type of boiler to the new vessels authorised.

Pembroke Dockyard.

The principal work at this yard is, of course, connected with the completion of the Royal Yacht *Victoria and Albert*, and the building of the armoured cruiser *Drake*, laid down four months since. As regards the former vessel, excellent progress is being made. A little difficulty has been experienced in getting the paint on the cabin bulk-heads, and other fittings to show as advantageously as was desired, and a number of coatings were found to be necessary before a good result could be obtained. This is supposed to be due to the action of the non-inflammable wood and to the chemical with which the wood is probably treated to render it impervious to the flames. As regards the *Drake*, which, it will be remembered, was commenced on the 24th of April last, it may be mentioned that the contract for the castings for this armoured cruiser has been given to the Steel Co. of Scotland, to which firm the wooden patterns for the cast-steel shaft brackets and stern-post have been sent off. The foundry at this yard does not boast of the plant necessary to permit the work to be carried out here.

The Perils of the Engine Room.

A little over a week ago a disastrous explosion occurred on board the torpedo-boat destroyer *Bullfinch*, resulting in the death of altogether 11 persons. It appears that the vessel had arrived at Spithead for the purpose of undergoing a series of tests prior to being taken over by the Admiralty. From the accounts published it appears that speed tests were being made over the measured mile in Stokes Bay. The engines were being run at their full capacity, when an explosion was heard, and a rush of steam came from the manholes leading to the boilers. The killed and injured were got out as soon as possible and transferred by means of a steamer launch to the cruiser *Australia*. One of the boat's crew said to a reporter that the shock of the explosion and of the escaping steam seemed as though it would rip the destroyer to pieces. Her engine-room hatches were all open, and through these the steam rose in hissing white columns high in the air. The efforts of the men on the deck at the time of the explosion to get into the engine-room were at first futile. Over and over again these brave fellows were driven back by the boiling steam, which also made its way into the open air by every crevice in the ship. It was like trying to enter a boiling cauldron, and yet the task was attempted repeatedly, with the result that several gallant fellows were badly burned. Ultimately the steam cleared away from the gangways sufficiently to enable the rescuers to make their way into the engine-room, although even then the work was difficult and dangerous in the extreme. The steam still half filled the engine-room proper, and through it could be dimly seen the bodies of the killed and wounded lying about the place. When the rescuers entered, the port engine was still working, and a large hole had been knocked in the vessel's bottom just by the starboard engine. Through this aperture the sea water was pouring in considerable volume, threatening to flood the compartment and endangering the safety of the ship. Meanwhile the port engine had been stopped and a collision mat was placed over the hole in the ship's bottom. Had this not been done very smartly, it is doubtful whether the vessel would have kept afloat long enough to get into harbour. All the men killed, with the exception of two named Ayres and Young, of Portsmouth Dockyard, were employed at Earle's Shipbuilding Co., the firm who built the *Bullfinch*. The connecting rod of the starboard engines broke and the piston knocked off the cylinder cover. The *Court Circular* of July 22nd contained the following message from the Queen:—"Her Majesty was much distressed to hear of the dreadful accident and loss of life on board the torpedo catcher *Bullfinch*." The adjourned inquest is to be held in about a week's time.

New Warships for Japan;

The Japanese Admiralty continues the policy commenced 10 or 12 years ago of building up a fleet of warships for Japan which shall be unequalled by any power in the Far East. There has just been launched at Elswick a new battleship, the heaviest ever built by Messrs. Armstrong, having a displacement of 1,500 tons. She is a little superior in H.P. to the *Majestic*, but has a slightly less coal capacity. Her length is 400 ft.; breadth, 76 ft. 6 in.; draught, 27 ft.; displacement, 15,000 tons; I.H.P., 14,500; and speed 18 knots. Her armament will consist of four 12-in. breech-loading guns, 14 6-in. quick-firing guns, and many smaller weapons. She will carry also four submerged torpedo tubes and one above-water torpedo tube, fixed in the stem. All the armament and the gun and torpedo machinery are of the Elswick design and manufacture. It has not yet been decided what type of 12-in. guns will be carried, as the Japanese authorities have determined to await the trials of a new Armstrong gun, 50 ft. in length, which is to be tested in the *Excellent* after the manœuvres. The *Hat Suse* was engined by Messrs. Humphreys, Tennant & Co., and is one of four sisters building in this country. The Japanese armoured cruiser *Yakumo* was launched the other day at the Vulcan Yard at Stettin. She has a displacement of 9,850 tons, and a mean draught of 23·9 ft. The engines are of 11,200 H.P. for a speed of 18 knots, but they can be worked up to 15,500 H.P., with a speed of 20 knots. One of the steam pinnaces to be carried by the cruiser will have two torpedo-tubes. Another interesting item of Japanese naval intelligence is the fact that the Japanese Government have placed orders with the Italian Terni Steelworks for a great number of armour plates to be made by this firm. The armour manufactured by the Terni Steelworks is said to be superior to that of both Krupp and Harvey. The arrival is reported at Yokohama of the torpedo-boat destroyer *Inadsuma*, which left Europe a month or so ago.

The French Navy.

The French Navy Department seems determined to go on with the building of submersible torpedo boats. Four of them, of the Narval type, are to be built at Rochefort, and at Cherbourg the other week the submarine boat *Morse* took the water. On the 24th of this month the battleship *Henri IV.* will be launched at Cherbourg, the *Suffren* having already taken the water at Brest a few days since. There are no indications that the French Navy puts faith in the Czar's disarmament scheme; for the estimates for next year are to be increased by about £370,000, and the French Navy League is doing all in its power to urge on the French people the necessity of a much stronger navy than France possesses at present. An outcry was raised in the French service papers recently about the defects in French warships, and apparently with good reason. The *Eclair* says that the engine frames of the ironclad *Bouvet* and of the cruisers *Lavoisier* and *Galilee* have been found to be seriously defective, owing to inferior metal having been used in their construction, that it is impossible to make repairs, and that the vessels will never attain their normal speed. The *D'Entrecasteaux*, cruiser, is said to be an out-and-out failure, and the authorities at Toulon are said to despair of her ever being rendered habitable or good for anything at all. She is as hot as a furnace, and it was found necessary before she left for Saigon to remove the powder from her magazines. There are to be no important manœuvres in the French Navy this year; and, with the exception of some steam tactics, long-distance signalling, and probably the working out of some simple tactical problems, very little will be undertaken.

Water-Tube v. Scotch Boilers.

The attack on the water-tube boiler in the House of Commons recently gave Mr. Goschen a chance to justify the action of the Admiralty in adopting this type of boiler for vessels of the British fleet. Mr. Allan initiated the discussion, but he could not produce any very new arguments against the water-tube, whilst Mr. Goschen was easily able to disprove his contention that this type of boiler is a failure. In a leader which appeared in the *Times* on the subject, the writer summarises the indictment of the water-tube type of boiler as follows:—Compared with the ordinary type of cylindrical boiler it is a large consumer of fuel, it needs the best kind of coal and distilled water for effective working, its tubes are liable to split if not kept scrupulously clean, it is short-lived, makes black smoke, and is a source of danger to those unaccustomed to its use. As the writer points out, however, good fuel and distilled water are merely questions of money, and "the fleet is not maintained for profit but for protection"; the answer to the next item of the indictment is, of course, that the tubes should be kept clean, and the other defects "can obviously be remedied by experience and training on the part of the firemen and stokers." The value of the boiler, it is claimed, is that steam can be raised more quickly with it than with any other type of boiler, a ship can be stopped more quickly, there is greater control over steam pressure, less danger to the stokers if a shell explodes in the boiler-room, and repairs are more easily effected. The truth appears to be that whilst we have yet much to learn about the type of water-tube boiler which best answers the purpose of the Navy, yet for strategical reasons, which must override all others in this connection, the water-tube type is far superior to the old cylindrical kind.

At the examination held on July 11th, 12th and 13th, the following candidate passed for extra first-class engineer, Mr. Robert Rioch, of South Shields. He was prepared by Mr. W. H. Thorn, 5, Waterville Terrace, North Shields. Sixty pupils have passed in the above grade from this establishment, being the highest record for any existing school in the kingdom.

MARINE ENGINEERS' NOTES.

(From our own Correspondent.)

THE Experimental Department of the Institute of Marine Engineers has had some additions to the experimental apparatus during the month. Mr. Sage has, with his own hands, constructed apparatus for demonstrating the laws of fluid friction. It will be used to prove that the intensity of pressure on the sides has no influence on the friction of fluids when flowing through a pipe. There are two tanks, cylindrical and vertical, and these are connected at the bottom by a long copper U tube. The water stands at a higher level in one of the tanks than in the other, and the friction is measured by the time taken for the water to flow from the one tank to the other. The fastenings of the seams of the tanks Mr. Sage has neatly made with rivets, and the construction of the copper tube leaves nothing to be desired. The apparatus is a valuable accession to the Experimental Department of the institution. Mr. Sage has also made a further contribution, which will provide all that is necessary for the new experiments to be made on forced draught.

Mr. Blelloch has presented a tank. Water in it can be supplied from it at a constant height for experimental purposes. It has been of the greatest service in almost all the experiments which have been made. The water can also be regulated so that it can flow through any tube at a given velocity. When under trial the water has been measured, and runs with wonderful regularity.

Mr. Blelloch has also constructed for the institute a pyrometer in shape like a calorimeter for measuring the temperature of a flame from any gas or fire. There is first an inside copper vessel covered on the outside with asbestos. Water is placed in this vessel. It is supported from the bottom on copper rods, and kept in the middle by copper rods projecting from the sides of an outer cylindrical copper vessel. The outer vessel has a copper cover, through which is inserted a thermometer. Suspended from the cover is also a platinum wire, carrying a small piece of copper. The inner vessel is thus insulated from cold by an asbestos cover, and next by air between the two vessels. The small piece of copper is placed in the flame, and then suspended in the water of the inner vessel. It raises the temperature of this by an amount shown by the thermometer. This rising of temperature of the water gives a measure of the temperature of the flame. Allowance is made for the rise in temperature of the vessel itself.

Mr. Brown has presented the institute with a small copper boiler for the purpose of supplying steam for experimental purposes. This will be permanently fixed in some place, and the apparatus requiring steam for any special experiment arranged round it. He has also given a copper spiral which can be heated, and when the steam is passed through, it is superheated. Mr. Brown has besides given a small copper tank with a regulating cock at the bottom.

There is also now in the institute a full set of apparatus for testing oil. The specific gravity can be obtained and the fractional distillation made, also the flash point and the calorific value of the liquid fuel. Determination of those values have been obtained for Borneo oil supplied to the institute.

The further experiments promised to investigate the influence of the velocity of water in tubes subjected to heat on the outside have been made and published in *The Engineer* of July 7th. The results of those in which the source of heat was Bunsen flames were even more remarkable than those in which the source of heat was steam. There is the same kind of rise of absorption measured in thermal units as with steam and there is a maximum point as before. But the fall after a critical velocity is more deliberate and pronounced. The shape of the curve is like a heat or expansion curve. One feature comes out very clearly, that is the dependence of the critical point on the quantity of the heat supplied. Sometimes the gas to the Bunsen burners was supplied in small quantities, in other cases it was supplied in great quantities. The effect of the change was to push further forward the maximum point. It came at a higher velocity the greater the quantity of heat supplied. To give an example. When the gas for the burner was supplied by one pipe and the supply limited at that, the maximum thermal units absorbed by the water were 9,075, and the speed of the water was measured by 110 cubic centimetres per minute; when more gas was supplied the maximum was 16,200 and the speed 200; and when as much gas as could be sent into the burner was used, the maximum was 21,360 thermal units, and the speed of the water when absorbing this quantity was measured by 480 cubic centimetres.

Mr. Fell has kindly given further apparatus to go a step farther in the investigation of this wonderful problem of circulation. The point to be determined is this. It will have been noticed that the temperature of the water taken into the tubes was the ordinary temperature of water in the mains. Now, this is not quite the condition of things in a boiler. We want the water boiling first before it is sent into the tube being heated, and then measure the evaporation which goes on. This evaporation may or may not be affected by the velocity of the water through the tubes; and there may or may not be a maximum point for some particular velocity of the water moving through the tube. Anyway, that is the problem to be settled by the apparatus kindly presented to the institute by Mr. Fell.

Meldrum, it is known, gets his forced draught by using steam from the boiler to induce a draught which is forced under the grate. A great quantity of steam is used and it appears to be wasteful, but very many of Meldrum's forced-draught apparatus have already been fitted on boilers throughout the country. It is possibly due to its simplicity, in spite of its wastefulness, that it is so popular. Another system, Gosling's, illustrated in our July issue, is getting widely taken up. Some recent trials with it in Scotland show its advantage when dealing with very bad coal. The evaporation was very excellent indeed with coal only costing 2s. 11d. per ton.

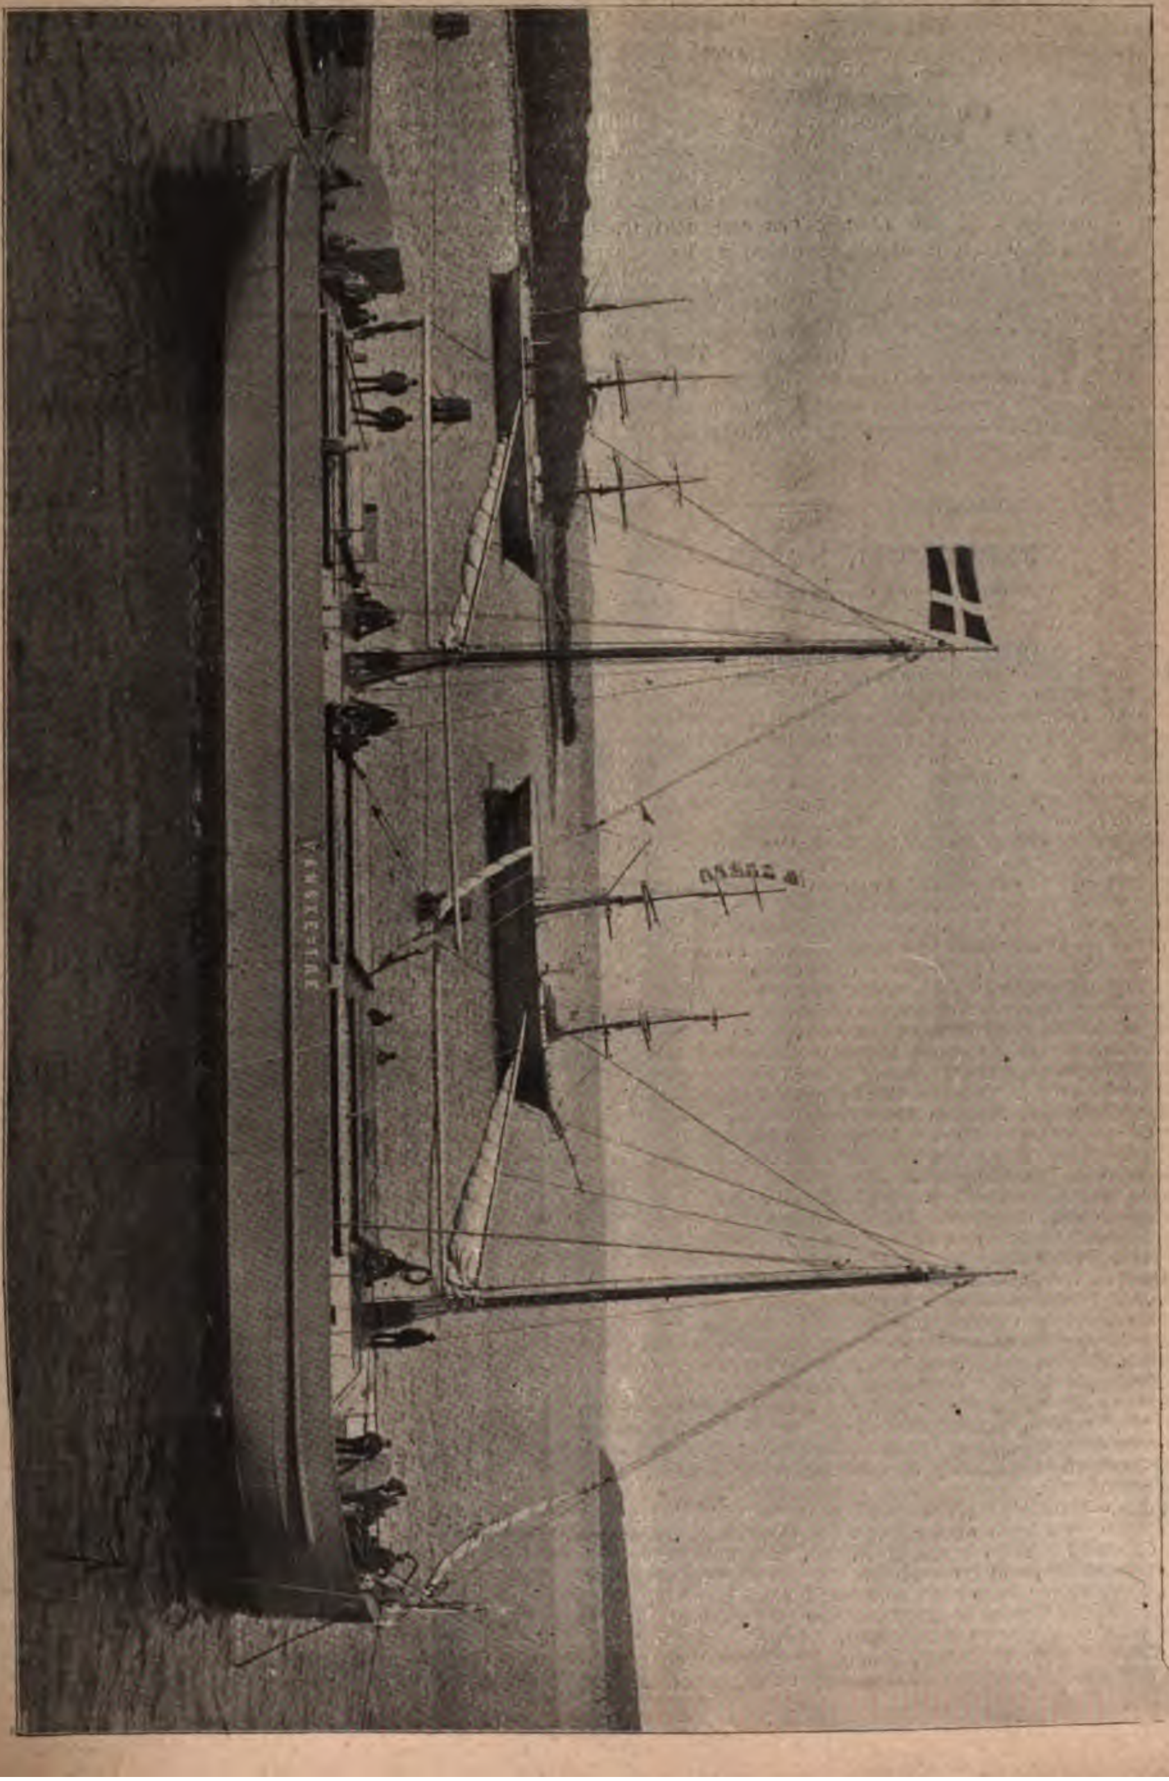
To marine engineers out on the India and China coast, it will be interesting for them to learn that two large steel river boats are to be built on the same system as the American Mississippi river boats, with large raised houses on deck from fore to aft, to ply twice weekly between Shanghai and Hankow, a distance of 690 miles. It will be a mixed goods and passenger traffic. The steamers will have twin-screws and triple-expansion engines, and they will make 12 knots an hour when fully laden. The steamers are to begin operation this month, and will sail under the German flag. The fuel is to be petroleum, and large storage tanks with a capacity for 90,000 tons are to erected on the Chinese and Indian coasts.

The institute apparatus for testing coal, presented by Mr. Macfarlane Gray, is contained in a nicely fitted box. Mr. Mather has been good enough to offer to make a similar box for holding and protecting the apparatus for testing liquid fuel.

The following is a list of the experimental apparatus in the Experimental Department of the institute:—

Description.	Presented by
1. Coal testing apparatus	J. Macfarlane Gray.
2. Radial valve gear model	R. Bruce.
3. Slide valve adjusting indicator ..	W. W. Wilson.
4. Sectional model of steam engine with Joy's gear	Jas. Stark.
5. Apparatus for circulation of water through annular tubes	Joseph Hallett.
6. Apparatus for testing the transmission of heat at different velocities of water	The Editor of the *Engineer*.
7. Water tank with fittings	J. Blelloch.
8. Tube for transmission of heat with hot gas as source	J. Blelloch.
9. Tools. Purchased	
10. Fluid friction apparatus	S. C. Sage.
11. Forced-draught apparatus	S. C. Sage.
12. Pyrometer	J. Blelloch.
13. Liquid fuel testing apparatus ..	
Box for holding liquid fuel apparatus	A. H. Mather.
14. Anemometer (on loan when wanted)	Jas. Adamson.
15. Apparatus for determining the influence of velocity of water at boiling point	W. Fell.

Marine Engineers' Examination.—At the quarterly examination of extra first-class engineers, held in July, Liverpool takes the lead this time again, and Messrs. Wm. A. Bryce, George H. Prockter, and Wm. T. Phillips were successful. The three candidates were prepared for the examination at Pritchard's Marine Engineering Academy, 8, Walton Road, Liverpool This makes 13 successful candidates at this academy for the last 18 months.



New Steel Lighter for Self-Trimming Purposes, built by the Flensburg Shipbuilding Co.

NEW STEEL LIGHTERS FOR SELF-TRIMMING.

(Patent, BREDSDORFF.)

WE show herewith a photograph of a steel lighter built for self-trimming purposes by the Flensburg Shipbuilding Co. It is a patent of Mr. Th. Bredsdorff, managing director of the said company. The dimensions of the *Danske-Tre* are 128 ft. by 30 ft. 1 in. by 9 ft. 3 in. depth, moulded, and the carrying capacity is 550 tons. The Flensburg Shipbuilding Co. has already delivered two lighters built on the same principle, but in a smaller size, and has three others of similar dimensions in stock. The owners of these lighters—the Danske Damper og Lægter Kompagnie, in Copenhagen—are full of praise of this system, and they are using them for the trade between all ports of the Baltic.

ELECTRICAL NOTES.

(From our own Correspondent.)

MR. H. HERBERT describes an invention in *l'Electricien* for prevention of collisions at sea. Two or more thermopiles are mounted on a vertical shaft, capable of rotation. These are shielded to exclude air currents and radiations from the ship, and from the sun, whether direct or by reflection from the surface of the water. The thermopiles are supposed to receive radiation from the approaching ship, and actuate relays of the d'Arsouval galvanometer type, ringing a bell when pointing in the direction of the approaching ship.

The Refrigerating plant of the Manhattan Refrigerating Co.'s New York Storage has many electrical fittings. The refrigerating medium is brine circulated by steam pumps. The brine and water pumps are worked in pairs by 20 H.P. belted motors at 250 volts, and these have to work in the wet. Switches and contacts are silver-plated to prevent chemical action with the salty atmosphere. Lampholders are of the porcelain waterproof type, hung by twisted cable from the outlet boxes. An enclosed switch, consisting of a glass tube stoppered at both ends, and containing a globule of mercury, when tilted in one direction, causes the mercury to join the iron terminals which pass through one of the stoppers. Motor fans to the number of 40 maintain the temperature throughout the storage room.

Westinghouse Electric Co.—The ramifications of this firm in America are so well known that we need only allude to it. But the company has decided and completed its arrangements for constructing works in England, and it is intended that within twelve months they shall be in full operation manufacturing electrical machines and steam and gas engines. The firm in England will bring over with it all the rights of the patents held by its sister in Pittsburg. The assistance of the staff of the firm in the New World will always be at the disposal of that in the Old. The old firm devotes at the present time one-fourth of the profits to research work. It is intended that the double firm will cater for the manufacture of steel and iron work for the British Empire, and it is said that similar works will be formed in France, Russia, and Germany. In all of them there will be the same governing power and the secret of the American success, complete standardisation, will be aimed at throughout the whole manufacturing system. British manufacturers will now have an opportunity of studying American methods at their own doors.

Volta.—Who has not heard in school (and everyone in England has been at school) of the frog's leg experiment discovered by Galvani? Volta heard of it, too, just about one hundred years ago, and he used the frog's muscle as an electroscope to discover the existence of small electric forces. With this crude instrument he discovered the properties of the pile and voltaic cell, and on March 20th, 1800, he wrote to Sir J. Banks, of the Royal Society, London, describing the pile. To commemorate this important discovery an exhibition is being held at Como, the birthplace of Volta. Volta was born on Feb. 18th, 1745. In 1774 he was appointed professor of physics in the Gymnasium of Como. In 1779 he was appointed professor of physics in Pavia. Napoleon, in 1801, called him to Paris to show his experiments on contact electricity. In 1819 he retired to his native town, and died on March 5th, 1827. The exhibition has been entirely destroyed by fire. Daring efforts were made to save the Volta memorials: the picture of Volta showing his battery to Napoleon and the sword of honour presented to him by the latter were rescued; but the only authentic portrait of Volta, his will, his valuable MS. and books, and his original battery were destroyed. The value of the exhibition was about £500,000.

The Maxim Incandescent Lamp.—Some time ago it was announced that Maxim had improved his lamp to such an extent that there was at least a saving of 25 per cent. in the number of watts required per candle. It is now announced that not only has this saving been made, but a manufactory is in course of construction in which 6,000 lamps will be made per day. The consumption of the lamps is from 2·8 to 3 watts per candle, as against 4 to 4·5 watts in the ordinary lamps.

The efficiency of Man as a Heat Engine.—Man eats and drinks and takes in energy by his food and gives it out again in the form of work by his hands or by walking. But there is much waste in the heat of the air of the breath, perspiration, &c. Dr. Marcet and Mr. Floris have been investigating the subject and have written a paper, read before the British Royal Society, where they show that the efficiency of man as a machine is a little less than 20 per cent. This is far above the efficiency of the ideal Carnot heat-engine with its boiler.

The Nernst Lamp.—The Nernst lamp is being made by the Allgemeine Elektricität-Gesellschaft in 25, 50, and 100 candle-power sizes, with a life of 300 hours and an efficiency of 1½ to 1¾ watt per candle power. The wholesale manufacture of 110 and 220 volt lamps will be commenced as soon as the new works are erected and completed.

The Bryan Marsh Co. have been experimenting with incandescent lamps. Incandescent lamps are greatly superior to arc lights in a fog, since the yellow rays of the incandescent light are not so easily damped out and absorbed as the rays of the arc light. The company have made a lamp of 5,000 candle power with two filaments, each taking 236 volts and about 3 watts per candle. The lamp thus took about 15 kilowatts. It burned out in three nights, due probably to the intense heat at the neck.

Electric Cranes.—Mr. Walter Pitt has read a paper at the conference at the Institution of Civil Engineers on "Cranes and the Power to be used with them." He compared steam, hydraulic, and electric power. The overhead traveller may be operated by a single motor or by three motors. The single motor runs continuously, and the different motions are obtained by means of belts or friction clutches. With three motors, each motor is geared to its own motion, and the type used on tramways may be introduced which have large starting torque. Liquid resistance has been used for controlling three motor cranes, but tramway controllers have also been introduced. In the three-motor crane with their series winding, the large current, says the *Electrical Review*, passes round the magnets at starting and so strengthens the gap field when the armature reaction is greatest, preventing sparking. There is no gearing, and the efficiency is necessarily greater than that of the single motor. Liquid resistances they regard as a makeshift.

India-rubber.—The manufacturers of india-rubber have good news from the Soudan. Sir William Garstin has sent in a report which has been received at the Foreign Office that on the White Nile the india-rubber creeper is found in great profusion. The plant has large laurel-shaped leaves and a white flower resembling a jasmine. He advises that the Assam india-rubber tree should be transplanted on the banks of the White Nile, and adds that, although the tree takes from twenty to thirty years to arrive at a girth sufficient to permit of regular tapping, its yield, which is about £3 per tree per annum, is so valuable that it is well worth attempting The ebony tree is also found on the Blue Nile and in the vicinity of the Sobat River. The trees from which white and red gum are taken are plentiful, iron ore is found in the Bahr-el-Ghazel, and gold mines are worked south of Fazogl.

Canal Boat Haulage.—A new system of haulage has been adopted in Belgium. It consists of a vehicle like a tricycle, to which is attached by an ordinary towing rope the canal boat. The vehicle runs along the bank, and takes the current from two overhead conductors strung by the side of the towing path. In Germany still another system is to be tried, which will consist of an electric locomotive running along a narrow-gauge railway, the necessary current being taken from an overhead trolley. Another system recommended by *Electricity* (New York) consists of electric motors running on cables carried on posts on the banks, and to which the boats are attached by two ropes. The motor may be controlled from the deck by means of two wires.

THE NOTTINGHAM UNIVERSAL AUTOMATIC FAIRY BOILER-FEEDER.

WE illustrate in the adjoining diagram a neat and compact design of an injector of the automatic type, which is manufactured by Messrs. Smith & Wilford, of the Great Central Injector Works, Queen's Road, Nottingham.

The main features of the design are:—Firstly, the suction, forcing, and delivery cones are formed in the same casting; secondly, the provision of a valve so arranged as to automatically close the vacuum chamber without interfering with the overflow passage; and, thirdly, the general arrangement of these parts and the steam cone with the outer casing whereby all the working parts can be removed and replaced in a simple and expeditious manner.

It will be seen from the illustration, of which Fig. 1 is an outside elevation, and Fig. 2 a sectional elevation, that the outer casing of the injector is divided into three chambers—viz., an inlet chamber, a vacuum chamber, and an overflow chamber, and that it is provided with four branches having connecting unions. The steam cone is fixed in the upper orifice and the combined cones are in the orifice opposite the steam cone. The right-hand orifice carries a guide for the vacuum chamber valve, which has a seat on the side of the vacuum chamber, the guide being, of course, formed to permit the passage of overflowing liquid. The left-hand orifice is connected to the liquid supply, and opens into the inlet chamber. The combined cone which passes through the vacuum chamber has openings into that chamber and into the overflow chamber.

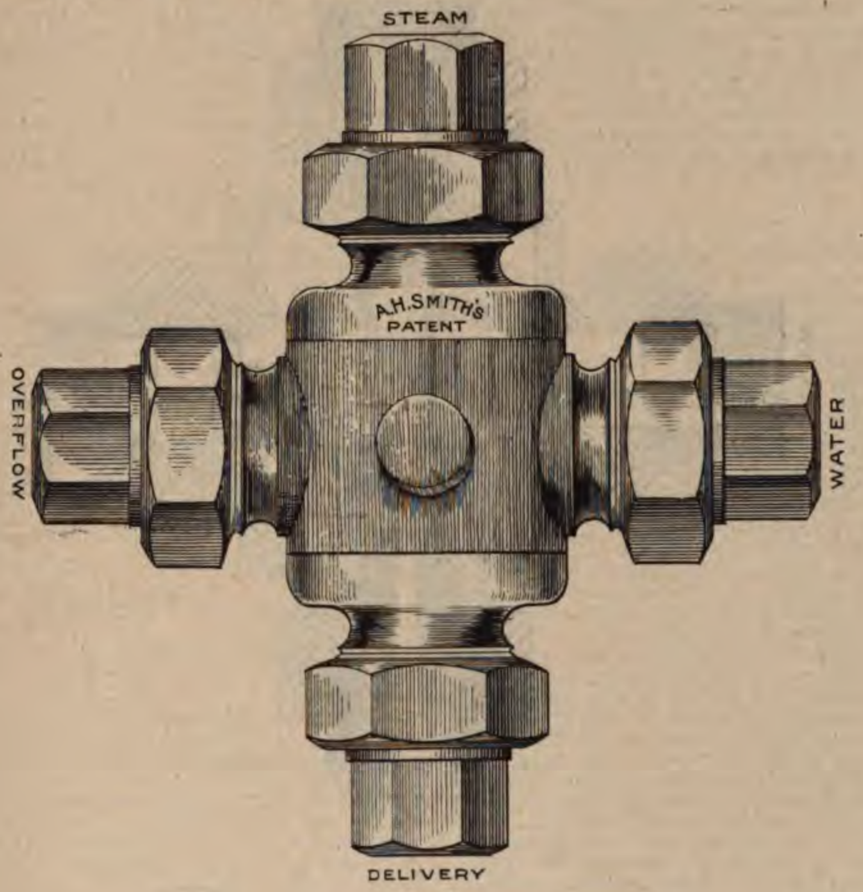


FIG. 1.

The steam and combined cones are mounted in the casing by means of screw threads, so that their relative position may be readily adjusted in accordance with the usual practice, and their final position is maintained by the pressure of the nipple of the union connection through the medium of the usual jointing washer.

It will readily be understood that the injector is automatic in its action; that the three cones, being formed in one piece, can be easily removed for cleaning and inspection; and that by the arrangement of the valve in the vacuum chamber the air and steam can escape in starting, and the chamber be closed automatically, when the injector starts to force the liquid, without interfering with the overflow passage.

The general simplicity and neatness of design should, we think, commend this injector to the notice of users of this type of water-raiser or forcer.

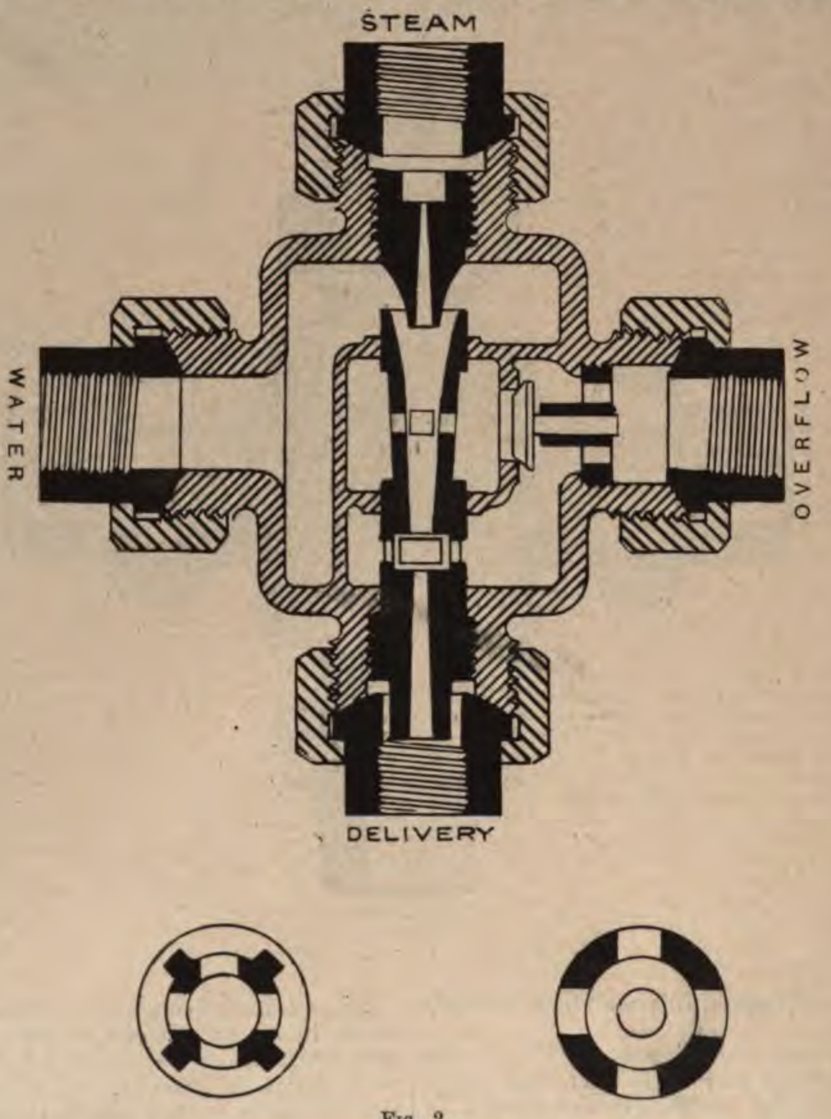

Fig. 2.

The Nottingham Universal Automatic Fairy Boiler-Feeder.

THE NEW UNION DRY DOCK AT LIMEHOUSE.

THE opinion has often been expressed for some years past that shipbuilding and ship-repairing is leaving the river Thames, and is going to the North and the East Coast, but the ceremony at which we had the pleasure of being present on July 22nd certainly afforded good evidence that the above statement is neither true in substance nor in fact. We refer to the opening of a new large dry dock in place of one previously on the same site by Messrs. Fletcher, Son & Fearnall, of Union Dry Docks, Limehouse.

The firm of Fletcher's is, of course, and has been for many years, a household word by the riverside, the original William Fletcher having established himself at Shadwell as a ship repairer in the 17th century. It is an interesting fact to note that in the 18th century the whole of the Isle of Dogs could hvae been bought for £10,000, and that a long lease could have been secured at a low rental of a very large portion of it. What a different aspect has been created in something a little more than a century, judging from the large number of extensive and successful commercial undertakings that are now crowded upon the island, and the thousands of residences which now exist for the working population employed in the industrial concerns now carried on.

The opening of the present dock illustrates very forcibly a forward step in engineering, inasmuch as it takes the place of a dry dock constructed in 1818, which can unhesitatingly be described as unique. It was at the time of the making of the Shadwell entrance to the London Docks that the proprietor, Henry Fletcher, found his then premises were compulsorily acquired, and he had to migrate elsewhere. He therefore secured the present premises at Union Docks, which he proceeded to extend. There had been for many years a breach in the river just below the two Union Docks and contiguous to them, and he endeavoured to construct a third graving dock.

The nature of the ground, however, making it an unexpectedly difficult undertaking, owing to a bed of quicksand, he purchased an old East Indiaman, called the *Canton*, sank her, fastened her down with through piles, erected gates at her stern, and formed a unique dry dock, which for 70 years, in fact until 1898, formed the third, or lower dry dock. When the extension was decided on in 1897, after consultation with the pilots, it was decided to excavate the dock at an angle of 45 deg. to the river, so that the most favourable position should be secured for dry docking on the flood tide. This meant the sacrificing of the old dock, and naturally the *Canton* had to be removed. This proved, as was to be expected, a formidable matter: the vessel, although over a century old, was built of English oak of heavy scantling, and was found to be in a perfect state of preservation, and so tough that each timber had to be split out.

The new dock was designed by the well-known engineers, Messrs. Kinniple & Jaffray, and the contract was secured by Messrs. Kirk & Randall, who started work on September 30th, 1897. It is 440 ft. long, 79 ft. broad at the coping, 60 ft. at the entrance, and is of concrete throughout, the bottom being pierced at every 10 ft. by 4 in. iron tubes to enable any possible future erosion in the ballast being made good by stock-ramming with clay or cement grouts. Danger of flotation, arising from an accumulation of water behind the walls, has been met by the insertion of a sufficient number of 4-in. pipes in them at the proper height to relieve the pressure. The pumping machinery is gas-driven, and in duplicate, developing some 340 H.P., capable of emptying the dock in from one to two hours. The engines were supplied by Messrs. Crossley Bros., Limited, and the pumps by Messrs. Gwynne & Co. The company have also provided, ready to leave at the shortest notice, a salvage plant consisting of two steam salvage pumps with interchangeable parts, and a craft provided with sleeping accommodation for the hands and their supervisors.

The ceremony of opening the dock was carried out by Mr. R. G. Fletcher and his party entering the dock at high water on board his steam yacht *Sweetheart*, gaily decked out with bunting, and breaking a floral garland which was stretched across the mouth of the dock. Immediately after the opening, the first ship to be docked, the s.s. *Hollinside*, was floated in, and docked for repairs, she having 25 plates out of her bottom from running ashore in the Baltic. During the luncheon which followed the docking of the ship, the water was pumped out of the dock, so that the guests had the opportunity of seeing the ship in dry dock.

The firm of Fletcher, Limited, are to be warmly congratulated on having made this extensive addition to their premises.

Amongst those who were present, both at the opening and the luncheon, were Sir W. Fortescue Flannary, M.P., Messrs. Sidney Young (Admiralty Registrar's Court), C. F. Torrey, W. Littlejohn Field, R. McAllum (Charlton, McAllum & Co., owners of the s.s. Hollinside), M Farqueland, of Clarkson & Co., and some 200 other visitors.

Reviews.

Ocean Rainfall by Rain-Gauge Observations at Sea. By W. G. Black, F.R.M.S. Edinburgh: E. & S. Livingstone. No date.

THE observations which are here recorded and tabulated were taken in the period between the years 1864 and 1881. They are, therefore, not very recent. But, considering the subject dealt with, the fact that the records have been taken accurately is of far more importance than that they should have been taken recently. We are told in the earlier pages how and by whom the phenomena noted were observed, and are thus furnished with good data to check the accuracy of the conclusions arrived at. Some of these are necessarily imperfect, as in many cases observations are altogether wanting for certain parts of the ocean. Monthly tables of the ocean rainfalls are, as far as possible, given for the various oceans, as well as for the northern and southern hemispheres. Another set of tables furnishes us with zonal summaries. In connection with these is given an interesting chart showing by its shading the incidence of the rainfall in the various zones of the oceans of the earth. In addition, a number of diagrams are afforded, whereby the relative rainfall in the various months is shown by dotted lines.

The work, which must have been excessively laborious, cannot fail to be of great value. For, though the crops of the world cannot be affected directly by the rainfall at sea, it is impossible to obtain any precise knowledge of the conditions which affect the small land surface of the globe on which we live without having regard to the very much larger surface where there are no trees and no mountains to attract the rain clouds. The theory of winds and air currents cannot be elaborated without the accumulations of records such as now lie before us, and we therefore welcome the volume as a valuable contribution to the sum of human knowledge.

The Slide Valve Simply Explained. By William J. Tennant, A.M.Inst.M.E. London: Dawbarn & Co. No date.

THIS booklet is the second of the Model Engineer series. It was, as its author tells us in his preface, originally written for the benefit of his railway students. It is now adapted for the use of all engineering beginners who wish to obtain a clear grasp of the working of the valve which plays so important a part in the economy of engines of every type. The true understanding of the characteristics and functions of this piece of mechanism is rightly held by the author to be of the greatest importance in the foundation of knowledge of mechanical engineering. "If," says Mr. Tennant, "the beginner can bring himself to believe that the slide valve is nothing more complex than a sliding shutter with a cavity in its face, travelling backwards and forwards over three ports, the outermost of which are alternately opened and shut to steam, and placed in communication with the central exhaust port, he will have made a satisfactory commencement." To help him to realise this initial fact, he would furnish the student with the means to make a cardboard model which shall be capable of graphically dealing with the principles and may enable him to wrestle in his leisure moments with the problems which arise in his studies. The idea which is here suggested is well and lucidly worked out in the pamphlet by the aid of many diagrams, and we feel sure that its study will be very valuable to all those who are commencing their engineering education.

Know your own Ship. By Thomas Walton, 1899. London: Charles Griffin & Co.

Mr. Thomas Walton may be heartily congratulated on having written the most successful book of the Nautical Series. It is but three years since it made its appearance, and already it is in its fourth edition. The bulk of the volume has in the meantime greatly increased as experience has made clear to the author how far the general readers of his work wish to go in their knowledge of the characteristics and behaviour of the wonderful machine in which they spend their working life. A new chapter on Trim has been added to the original book, this chapter embodying the points of a paper, which, under the same title, was read in March, 1898, before the Shipmasters' Society of London. The chapter on Stability occupies a great part of the book, and, indeed, it is one of the most important subjects to which the attention of the modern seaman can be turned. Section 3 of this chapter deals with that important phase of the question which comes under the head of ballasting. As Mr. Walton truly says, want of knowledge on this point has led to the loss of many a fine ship. As the size of steamers and their depth increases, the importance of this question seems to increase also. Some remarks are made as to the position of the registry offices in regard to this point. Referring to the common phrase, "cellular double bottom all fore and aft for water ballast to Lloyd's requirements," he points out that this does not in any way mean that the arrangements for ballasting the vessel are at all approved by Lloyd's, or any other similar body. No registry society touches on the important point as to whether or no the provision for ballasting the ship be proper. All they do is to certify to the strength of the receptacles, if any, provided for the water ballast, and say nothing as to whether or no they may be sufficient in capacity for their purpose. He is careful to explain that he says this not to find fault with the registry societies, who are clear enough to understanding people in their explanations as to what they consider their functions. But he dwells on the matter because he wishes to point out the error of those headlong people who will not, or cannot, understand what they read, and who rush to conclusions that because something is said about one aspect of a ballast tank, that must be taken to mean approval of it from quite another point of view. The chapter on Water Pressures has been very largely re-written, and the book is now one that can be most advantageously studied by every sea-going officer, whether his duties lie on the bridge or on the starting platform.

It is pleasant to learn that the author is now engaged upon another volume for the same series, to be entitled, "The Construction and Maintenance of Steel Ships." We feel sure that this volume will be a valuable addition to the library of which it is to form a part.

NAVAL ENGINEER APPOINTMENTS.

The following appointments have been made at the Admiralty from June 26th to July 25th, 1899:—

Austen, E. J., staff engineer to the *Duke of Wellington*, for the *Intrepid*, to date July 8th.

Blake, A. B., staff engineer to the *Duke of Wellington*, for the *Pallas*, to date June 29th.

Cole, W. G., assistant engineer (temporary) to the *Diadem*, to date July 3rd.

Emdin, A. R., engineer, has been promoted to the rank of chief engineer in her Majesty's fleet.

Emdin, A. R., chief engineer to the *Pelorus*, to date July 1st.

Hearn, J. H. C., probationary assistant engineer to the *Diadem*, to date July 19th.

Huddy, T. B., engineer to the *Duke of Wellington*, for the *Vulture*, to date June 27th.

Knapman, H. T., engineer to the *Pembroke*, for the *Avon*, to date July 7th.

Manning, H. L., chief engineer to the *Pembroke*, for the *Audacious*, undated.

Michell, W. H., fleet engineer to the *Vivid*, for the *Edgar*, undated.

Odam, E. K., staff engineer to the *Duke of Wellington* for the *Fox*, to date July 7th.

Rattenbury, E. J., retired staff engineer, has been advanced to the rank of fleet engineer in her Majesty's fleet.

Shirvell, J., fleet engineer to the *Vivid*, for the *Calypso*, to date June 26th.

Smith, W. A. P., engineer to the *Pembroke*, for the *Haughty*, to date July 7th.

Stevens, W. C., engineer to the *Pembroke*, for the *Bittern*, to date July 8th.

Tregenna, H. E., engineer, has been placed on the retired list of his rank.

Webb, A. T., acting chief engineer, has been confirmed as chief engineer in her Majesty's fleet.

Wright, J. R. B., fleet engineer to the *Vivid*, for the *Bellerophon*, to date June 26th.

Yeats, H. T., engineer to the *Pembroke*, for the *Cygnet*, to date July 8th.

INDUSTRIAL AND TRADE NOTES.

THE CLYDE AND SCOTLAND.

(*From our own Correspondent.*)

JULY being the great holiday month on the Clyde, the output of new shipping from the building yards is usually much below the average, and this year the July instalment will form no exception to the rule, although, at the date of writing these notes, there still remains a week to complete the period. The annual Glasgow Fair holidays began on the 14th of the month, and they were responsible for almost a clear fortnight's cessation of operations in most establishments in the upper reaches of the river. The works in the lower reaches—Port-Glasgow and Greenock—had their holiday period ten days earlier.

This year industrial Glasgow set out on its annual holiday under financial and economic conditions of the most favourable kind, and very fortunately to this was added highly favourable auspices as to weather. All classes of workmen have not only been well employed, but they have been receiving good wages. The iron, steel, coal, shipbuilding, and engineering industries of the Clyde and the whole West of Scotland were never more prosperous, nor have those directly associated with these industries received for a long time a better return for the capital invested and the labour expended. This highly gratifying situation is happily likely to exist for some time, as apart from the lull in the placing of new work on the Clyde, on which I have commented in previous issues, there is as yet no evidence of a turn in the tide of the commercial prosperity of the district. Happily, too, there is now a better understanding between capital and labour, thanks to the formation of boards of conciliation in the iron, steel, and coal trades, and the spirit of reasonableness and frank cordiality which is evidenced in the negotiations in matters of difference between employers and employed in the shipbuilding and engineering industries.

Although shipbuilding during June, and what has passed of July—as evidenced by the number and tonnage of the vessels launched—has been carried on with continued briskness, the tonnage output might well have been greater than it has, considering the number of contracts pressing for completion as well as the fact that prior to the annual holiday stoppage the workmen are steadier than at any other time. Altogether about 36,100 tons were turned out during June, as compared with 48,000 tons in June of last year, and 30,000 tons the year previous. That the present figure is only an average one may be accounted for by delays through sluggish or irregular supply of material from the steelworks which are still taxed to the uttermost and in operation night and day.

The June output was made up of 15 steamers for the merchant service, one screw gunboat for the British Government, four steam trawlers, one steam dredger, nine barges and lighters, and several small yachts. The largest steamer was the *Tagus*, of 5,500 tons, built by Messrs. Robert Napier & Sons, Govan, for the Royal Mail Steam Packet Co.; the next in point of tonnage was the *Rajah*, of 4,500 tons, built by Messrs. Charles Connell & Co., Scotstown, for the Asiatic Steam Navigation Co., Liverpool, and there were five other steamers of between 3,000 and 4,000 tons. The war vessel launched was the screw gunboat *Thistle*, from the yard of the London and Glasgow Shipbuilding Co., Govan. The June quota brings the total output for the six months of the year up to 233,000 tons, or about 25,500 tons in excess of the output for the same period last year, representing in fact an excess over any corresponding period in the history of the industry. During the first fortnight of July nine vessels were launched, aggregating 13,900 tons, the largest being a steamer of 6,700 tons from the stocks of Messrs. Scott & Co., Limited, Greenock, for the Ocean Steamship Co., Liverpool.

Whilst the tonnage output for the first half of the year reaches to an unprecedented figure, the tonnage still in hand is as yet plentiful, but the cessation in placing new work, which set in four or five months ago, is still very marked. Unless matters improve soon vacancies will begin to be evident in some of the yards. Although delivery is not now so uncertain, owners still apparently prefer to wait uncommitted till the prices of material are somewhat less than they are at present, and the chances of prompt delivery are still better. How matters stand in these connections may be judged of from the fact that more than one Clyde builder is in the position of not having bought material sufficient even for present requirements, and is holding back from doing so till the turn of the market. More than one boat in frame, it is believed, is stuck because the builder cannot afford to buy the material at present abnormal rates.

The contracts reported during June and July are:—A twin-screw hopper dredger for Japan, and a large and powerful hopper dredger for the Suez Canal Co., both to be constructed by Messrs. William Simons & Co., Renfrew; a hopper dredger for the Llanelly Harbour Board, by Messrs. Fleming & Ferguson, Paisley; two steam trawlers for the Ocean Steam Trawling Co., Aberdeen, by Messrs. Mackie & Thomson, Govan; a steam launch for an Irish owner, by the Clyde Patent Slipway Co., Greenock; a paddle-steamer for Chinese river service, by Messrs. Blackwood & Gordon, Port-Glasgow; a sailing barque of 3,000 tons for Messrs. Browne, Watson & Co., Glasgow, and two mail steamers of 18 knots speed for the Roumanian State Railways, by Messrs. Robert Napier & Sons, Govan.

The hopper dredger above noted as having been contracted for with Messrs. Simons & Co. by the Suez Canal Co. is intended for improving the entrance of the Canal at Port-Said, and she will be the largest and most powerful dredger ever constructed. She will be 270 ft. in length, 48 ft. in breadth, and 19 ft. deep amidships. She will have hopper capacity for 2,200 tons of dredging, and the bucket ladder will dredge to a depth of 40 ft. The lifting capacity of the vessel will be 1,500 tons per hour, each of the buckets lifting about two tons of material.

The order secured by Messrs. Blackwood & Gordon, Port-Glasgow, is for the hull of a light-draught steamer only, to be taken down after erection and shipped to its destination in pieces. The engines and other machinery will be provided by Messrs. Denny & Co., Dumbarton. In fact, the order has been placed with the Port-Glasgow firm by Messrs. Denny & Bros., who have for some little time had more work of this character than they could conveniently tackle. Besides having sub-contracted with Messrs. Blackwood & Gordon, and also with

Messrs. Alley & Maclellan, of Polmadie, for the completion of hulls, the firm have found it necessary to utilise surplus ground belonging to them lying outside their yard wall for work of this class, and they are now completing the erection and fitting out with machinery of new sheds alongside.

Whilst speaking of Messrs. Denny & Bros., it may be noted that Mr. Archibald Denny, one of the partners of this eminent firm, has recently been visiting the shipyards of the United States in the course of his tour round the world, which was begun in November last, when he left Scotland for Burmah. Since then he has observed shipping methods in the Irrawaddy and Bramaputra rivers, India, in which regions innumerable steamers and barges built by his firm are employed; also at Melbourne and Sydney and in New Zealand, about which regions the same remark might almost be made. Crossing the Pacific, he has visited San Francisco and Newport News, Philadelphia, Washington, &c. Mr. Denny's previous visit to Philadelphia was made in 1882, and he has remarked wonderful progress as regards shipbuilding in the States since that date. Mr. Denny was expected back in Dumbarton again about the last week in July.

The order for a sailing barque booked by the Ailsa Shipbuilding Co., Troon, is noteworthy in two ways. The vessel will be the largest—3,000 tons deadweight capacity—as yet undertaken by the builders, and the placing of the order now, when steamers cannot be had fast enough, indicates that everyone has not yet quite lost faith in the sailing ship. With the exception, however, of the four-masted schooner ordered about two-and-a-half months ago by Mr. John Ena, of Honolulu, from Messrs Robert Duncan & Co., Port-Glasgow, this is the first order for a sailing vessel that has been placed on the Clyde for a comparatively long period. The last sailing vessel, of any size, turned out by Clyde builders was the *Inverclyde*, launched by Messrs. Russell & Co., Port-Glasgow, early last year.

Messrs. Anderson, Rodger & Co., shipbuilders, Port-Glasgow, have been granted a renewal of their lease of the graving dock owned by the Port-Glasgow Harbour Trust. That body have also resolved to accept the offer of Tangye's, Limited, Birmingham and Glasgow, to provide new engines and pumps for the dock. The dimensions of this dock—which was constructed in 1873-74, and superseded an older one, dating from 1762, the first graving dock, in fact, formed in Scotland—are: length, 310 ft.; entrance width, 45 ft.; depth of water on sill at high water of spring tides, 16 ft.

The vacancy in Lloyd's Register Committee, caused by the death of the late Mr. T. C. Guthrie, Glasgow, has been filled up by the election of Mr. William Law, of Messrs. Thomas Law & Co., shipowners, who now joins the committee as the representative of the Clyde Sailing Ship Owners' Association.

With the formal opening of the new graving dock at Troon by the Marchioness of Ailsa, which event took place—as more fully detailed elsewhere in this issue—on the 29th June, the Ailsa Shipbuilding Co., who will work the dock under arrangement with the Duke of Portland, who owns it, have not only had their facilities for docking and repair work immensely enhanced, but have had an increase made to their yard area, and the addition of another building berth. Through the provision of pumping machinery capable of serving both the new dock and the one formerly existing, the engines up till now serving the latter are dispensed with, and they are being taken advantage of to drive the firm's saw-mill and wood-working machinery. For particulars as to the dimensions and capacity of the new dock, I refer readers to the illustrated account elsewhere given in this issue.

Mr. George Brown, who for the past eight or nine years has been yard manager with Messrs. William Denny & Brothers, Dumbarton, has resigned that position, and intends starting business as a shipbuilder, along with other partners, somewhere on the Clyde, probably in the vicinity of Clydebank or Yoker, in anticipation of the passing of the Clyde Trust Bill providing for large tidal docks there. Mr. Brown, who as a young man was a brilliant student under the auspices of the Science and Art Department, bringing the much-coveted gold medal north of the Tweed, gained his experience in the shipyard of Messrs. Alex. Stephen & Sons, of Linthouse. Going to Messrs. Denny & Brothers, about 18 years ago as a leading draughtsman, he in time rose to be chief, and about eight or nine years ago, as stated, he was promoted to the managership of the outside work of the shipyard, Mr. John Ward, partner in the firm, and formerly yard manager, however, retaining much of the responsibility.

The Campbeltown Shipbuilding Company, whose stocks are kept constantly occupied, have received during the month an order for another screw-steamer for the Bristol Steam Navigation Co. of Bristol, a sister vessel to the s.s. *Silvio*, which the company built for them some time ago, and intended to replace the s.s. *Cato*, also built by the Campbeltown Co., but which was lost off the coast of Cornwall during the heavy storm in March last. The new vessel, like her sister ship *Silvio*, is to be of the part awning-deck type, 230 ft. long between perpendiculars, 32 ft. 8 in. beam, 17 ft. 6 in. depth moulded, and to have a deadweight capability on Board of Trade freeboard of close on 2,000 tons. Engines capable of driving the vessel 10 knots when loaded will be supplied by a Glasgow firm, the Campbeltown Co. not being themselves engineers. They have also on the stocks at present a steamer 290 ft. long and 3,400 tons deadweight.

For the erection of a new general engineering works, Messrs. Speedie & Motion, Glasgow, have feued four acres of ground at North Motherwell, and operations will at once be begun. Negotiations are also in progress for the transference of a foundry from a neighbouring town to North Motherwell. A large and commodious new boiler shop has been added to the works of Messrs. J. Dalgleish & Son, engineers, of Pollokshaws.

Messrs. Stevens & Struthers, brass and bronze founders, well known for their specialities in the way of sirens for use on board ship and in lighthouses, as well as for their production of the heavy and intricate bronze castings—stems, stern posts, propeller brackets, &c.—for Government cruisers, gunboats, &c., have now removed from their old premises at Cranstonhill, and occupy splendid new works at the foot of Kelvinhaugh Street, Glasgow. The shops and yard area are much more extensive than in the old works, and they are lit throughout by electricity. Electricity is also used to drive most of the machinery, overhead cranes, &c.

The watertight windows and doors to which reference was made in these notes in the June issue, as being fitted to a steamer then on the stocks in a Clyde yard, are the invention of Mr. James Hamilton, one of the partners in Messrs. Robert Napier & Sons, Govan; and the vessel in which they are fitted is the Royal Mail Steam Packet Co.'s steamer *Tagus*, which, as already mentioned, was launched from the yard of the firm named in the last week of June. Apart from the material of which they are made—this being a special white metal, the invention of Mr. Lawson of the New Howe Machine Co., Bridgeton, Glasgow, having properties which insure for it extended adoption in shipbuilding—the windows and doors are distinguished from others in having applied to them the principle of air compression for watertightness. The application consists of a pneumatic tube of rubber, which is let into a recess running round the fixed frame of the window or door, and which when the opening frame is closed, presses against the tube in the fixed frame, the closing action inflating the tube thoroughly and thus rendering the contact of the two frames thoroughly watertight. The *Tagus* has as many as 240 of such windows fitted along her deck-houses, all of larger dimensions than usual, and the weight of these, in the aggregate, is less by about 14,160 lbs. than if they had been made of cast iron.

Riveting the shell plating of ships by mechanical, in place of manual power, has long been striven after by shipbuilders, and the inventors they have called to their aid. but up till the present no very satisfactory solution of the problem has been arrived at, although numerous appliances have been tried, and modifications have been made in structural methods in order if possible to meet the machine-tool maker half way. It has become pretty well known that developments in this special and highly important direction have been going on in America, especially in the Chicago Shipbuilding Co.'s. premises, as was gathered from the elaborate paper on pneumatic riveting, read at the recent Civil Engineering Congress by Mr. Babcock, the manager of the Chicago Company's yard. The tools there referred to are those made by the Chicago Tool-Making Company, but improved in many details by the Shipbuilding Company. An installation of similar tools, along with all needful plant in the way of air-compressing engine, piping, &c., has recently arrived in the Clyde, and is being applied to actual work in various yards by Messrs. John Macdonald & Son, of York Street, Glasgow, representing the Agents-in-general, Messrs. Taite, Howard & Co., London. Demonstrations have already been given in the shipyard of Messrs. Alexander Stephen & Sons, Linthouse, when the action of the tools—which are operated by American workmen specially sent over with them—was favourably commented upon by representatives from a large number of the most important yards on the Clyde, at Belfast, and from Sunderland.

Whilst the admiration for the drilling, chipping, and caulking tools and for the deck and tank top riveter was unstinted—these tools having already highly approved themselves in yards, boiler-shops and locomotive shops all over the kingdom—it was the shell-riveter that was the centre of greatest interest. The work done by it, however, on the shell of a large ship, it was felt left something to be desired. The effective closing of the heavy and curved plating seemed scarcely to be attained by the machine shown, and, whilst this can be remedied no doubt by increasing the pressure applied and the calibre of the machine to do the work, this means increase of weight, and it is largely due to the lightness and great adaptability of the pneumatic over the hydraulic system of tools that the former are being regarded with such favour by shipbuilders determined to have mechanical substituted for manual labour in shell-plating. As to the descriptive details, and views of the tools at work, I hope to communicate these in a separate article later. The tools are about to be taken to the yard of Messrs. Russell & Co., Port-Glasgow, and thence, after a week or two's thorough trial, to that of Messrs. Denny & Brothers, Dumbarton, when even a more important public demonstration of the capabilities of all the tools, and especially the shell riveter, will be given.

The question of Clyde New Docks, and rival promoters. with which the air around St. Stephen's has been thick for many weeks, and with which the columns of Clydeside journals have been full and overflowing for the same period, may be disposed of here very shortly, until at least what is actually to come out of it all is better known. So far as the fate of the Renfrew Dock Bill is concerned, history has repeated itself at Westminster. The measure has for a second time in succession found favour with a Select Committee of the House of Commons, and as it was passed over two months ago by the Upper House, its success may now be looked upon as assured. The Bill for docks promoted by the Clyde Trust has by no means been so fortunate. According to the proposals it contained, two new docks were to be constructed, one at Shieldhall, on the south side of the river, and the other at Clydebank, farther down on the north side. The House of Lords Committee allowed both to "go forward," but the Commons Committee have ruthlessly divided the scheme, and, whilst granting powers for the making of the Clydebank Dock, have refused those in connection with Shieldhall. On the merits of this decision conflicting views are certain to prevail on the Clyde; but, however high feeling may run, it will be generally allowed that the committee have discharged the duties entrusted to them in an able and impartial manner. The mere facts that the proceedings lasted over three weeks, and that 15 working days were occupied with the examining of evidence and the delivery of speeches, are enough to show that the inquiry has been of the most thorough and exhaustive kind. From all this it seems to follow that greater importance than usual ought to be attached to the decision of such a Committee. For the Renfrew Corporation and Mr. Spiers, of Elderslie, who has so stoutly and persistently backed it in the matter, it means that their hopes and expectations are about to be realised. Whilst it has been resolved that their scheme can be carried out in its entirety, the Clyde Trust have virtually been told that two docks embraced in their scheme was one too many, and so having given Renfrew sanction to build one on the south side of the river, the committee have struck out Shieldhall and restricted the trust to extra accommodation on the north side. It should not now be long before events declare which side has been most genuine and most justified in seeking powers for new dock accommodation on the river.

Although trade in the shipbuilding yards of Dundee has been fairly good for a considerable time past, there have been very few new orders booked; in fact since the beginning of the year only two orders of any consequence have been booked. The latest of these is a twin-screw passenger steamer which Messrs. Gourlay Brothers & Co. have contracted to build for a New Zealand firm. The vessel is to be specially designed and handsomely fitted for the passenger trade, and will be 190 ft. long, 30 ft. broad, and 13 ft. 6 in. deep, with a tonnage of between 700 and 800 tons gross measurement. On the 12th ult. the firm launched an ice-breaking and passenger steamer to the order of the Canadian Government, which was named *Minto*, in honour of the Earl of Minto, the Governor of Canada.

Mr. George C. Buchanan, engineer to the Dundee Harbour Trust, has had his salary increased from £450 to £600 per annum. There was some chance of Mr. Buchanan being placed on the short leet of candidates for the post of chief engineer to the Aire and Calder Navigation Trust, the salary attached to which is £1,000, but in view of the increase granted to him by the Dundee Harbour Board, Mr. Buchanan telegraphed withdrawing his letter of application.

THE TYNE.

(From our own Correspondent.)

Shipbuilding — The visit of the Naval Architects to the North this year has been in every way a success, and it would, we think, be somewhat difficult to say which will recall with most pleasurable feelings the proceedings of the week—the visitors or the visited. It is certain that the arrangements made for ensuring the comfort and convenience of the former, and giving them generally a pleasant time during their stay were very complete indeed; and the heartiness and goodwill displayed by the local gentlemen who had the advantage of being present at the various functions in the week's programme, were no less conspicuous. The visitors, wherever they went, proved themselves appreciative guests, and there cannot be the least doubt that this meeting of associates of an institution connected with the greatest industry of the age will have resulted in many new friendships being formed between leading men in shipbuilding and engineering, and many old ones being cemented This, of course, is only by the way. A result of much greater consequence, which may be looked for, is the stimulating effect of having productions, and the manner of production, brought directly under the observation of the most capable experts. Such contact as this is beneficial to all concerned, and acts as a spur to scientific progress; and it cannot be denied that the annual gatherings of the members of the Naval Institute are doing a great deal of valuable work in this special direction.

Simultaneously with the visit of the Naval Architects two important announcements have been made, which, when carried out in their entirety, will give to the district of the Tyne more prominence than ever amongst shipowners and commercial men generally. The first of these refers to Jarrow Slake, in which spacious water-covered area two pontoons are to be placed, either of which will be capable of taking on the largest vessel afloat. Workshops, shearlegs, cranes, and all the other necessary appliances for carrying on a large engine and ship repairing business will be provided, and the contract for making a new quay and other improvements of a kindred kind has, we understand, already been placed. This enterprise is being undertaken by the Smith's Dock Co., of North Shields, who some months ago acquired as much of the area as they deemed requisite for the purposes intended, as mentioned in the MARINE ENGINEER at the time. A new forge of considerable extent and up-to-date equipment is approaching completion in the vicinity, and it is probable that in a very few years from now this once comparatively dull and deserted locality will become the scene of as much activity as can be witnessed at any other centre on the Tyne.

The second announcement refers to the great developments that are about to take place in connection with the firm of Messrs. Robert Stephenson & Co., shipbuilders and engineers, of Newcastle and Hebburn. A new company is being formed, of which Sir Joseph Pease is to be chairman and Sir Christopher Furness one of the directors. The names of several other gentlemen of eminence in the industrial world have been mentioned in connection with the enterprise, which is sure to add largely to the commercial importance of the Tyne. Among other projects contemplated by the new directorate is the formation of a large graving dock in contiguity to the Hebburn yard, and this undertaking, it is expected, will be started at once. It will be capable of accommodating vessels of the very largest class, and will be provided with every modern accessory which is requisite to ensure effective and economical working. The existing works, including the shipyard and engine works, are, it is understood, to be extended and developed, and there is every reason to expect that the whole establishment will be placed upon a footing of equality with the leading industrial concerns in the kingdom. We understand that an order for a large passenger vessel of the twin-screw type, has been placed with Messrs. Hawthorn, Leslie & Co. by the syndicate who represent the Russian Volunteer

Fleet, and that she is to be fitted with water-tube boilers, which, as well as the engines, are to be constructed at the firm's St. Peter's Works. This eminent Tyneside firm have built many very superior vessels for the same owners, the last being, we believe, the s.s. *Kherson*, which, as she lay in the river during the fitting out period, was the object of universal and exceptional interest. It is no exaggeration to say that the *Kherson* was amongst the very finest vessels that ever left the Tyne, and it is satisfactory to find that the Russian gentlemen who cater for the requirements of the celebrated fleet referred to, are so well satisfied with what they got from the firm on former occasions that they come back to them when another vessel is needed. The firm have some meat ships still in hand, and have commenced the construction of the torpedo-boat destroyers ordered by the Admiralty. In the graving dock a vessel of large size is receiving an extensive overhaul.

At Messrs. Swan & Hunter's yards business continues exceedingly brisk, and it is thought probable that a further accession of work will shortly come to the firm in the shape of a contract for the two great pontoons about to be constructed for the Smith's Dock Co. Nothing is as yet definitely known as to the placing of this contract, but it is very generally admitted that Messrs. Swan & Hunter have unique facilities for dealing with this kind of work, having already beaten all records as far as regards rapidity of construction; and it is therefore considered probable that their selection for the execution of this important work, is assured.

Messrs. Armstrong, Whitworth & Co. are still engaged in extending the building capacity at their Low Walker Yard, and are also carrying out other improvements, which it is expected will prove very valuable when completed. The company have contracted for the building of two or three more ice-breaking vessels, one of which, it is said, will be of even greater size and power than the now celebrated *Ermack*. The latter vessel, in the short time it has been afloat, has achieved marvellous feats in releasing vessels from imprisonment in ice-bound seas, and in view of the wonderful capabilities exhibited by this remarkable vessel, it is certain that the frozen regions of the north will in future be more accessible to navigators than they have been.

Messrs. Wigham, Richardson & Co., Limited, are reported to have received from a well-known Hamburg firm of shipowners an order for a cargo boat of very large carrying capacity and generally superior equipment. The engines and boilers will also be supplied by the firm, who, it is expected, will be able to give delivery by the end of 1900.

The Northumberland Shipbuilding Co., who have a large amount of work in progress on the stocks, have, it is understood, arranged with a newly formed company for the building of a large cargo boat, the engines for which will also be constructed on the Tyne. The firm have recently launched a fine vessel, ordered by Newcastle owners, and they have another well advanced towards completion.

Notwithstanding the scarcity of new business in shipbuilding, which subject has been the almost universal theme of conversation in commercial circles for some weeks past, it is understood that the Palmer Co. have booked some orders lately, though particulars are not forthcoming. Many people believe that it is the high price of tonnage which is the principal hindrance just now to the placing of new orders; but we venture to think that, if the need for additional tonnage were very urgent, no considerations as to cost would prevent the giving out of orders. The truth is that at present the shipping trade is not in too flourishing a condition, and until an improvement takes place, it is useless to expect any special liveliness in the ordering of new tonnage.

The Tyne Shipbuilding Co. continue to have plenty of work in progress, and at Messrs. Readhead's yard the usual state of activity is noticeable. Messrs. Wood & Skinner's and Messrs. Dobson's yards are fairly busy, and at Eltringham's and other establishments, where only vessels of a small class are built, the building berths are fully occupied.

The graving docks at various centres on the Tyne are just now being fully utilised, the vessels in hand for repairs or painting being considerably in excess of the average at this time of year.

Engineering.—At the St. Peter's Engine Works business has been very brisk for a long time, and now a further accession of work has come, which will help to keep things briskly going over the winter months. We refer to the twin engines for the newly ordered Volunteer boat, which will, it is understood, be put in hand as soon as practicable. The Neptune Works at Walker are well supplied with orders, and at the Wallsend Slipway Works business continues exceedingly brisk.

The Palmer Co.'s engineering department is showing well sustained activity, and the same may be said respecting the engine and boiler shops at Messrs. Readhead's. Both the marine and locomotive departments of Messrs. Stephenson's South Street Works are kept actively going, and at Messrs. Hawthorn, Leslie & Co.'s Forth Banks Works a similar condition of briskness is to be witnessed.

Messrs. Dinning & Cook, of the Percy Ironworks, Newcastle, have acquired a site at Walker Gate, on which they contemplate erecting a large iron foundry and a pattern-making shop, both of which will be fitted with modern machinery and appliances of the most approved descriptions with a view to the production of high-class castings. There is just now a large demand for superior castings from electrical and general engineering firms and from shipbuilders, and to cater for this ever-widening market, with some degree of success, is the expectation of the well-known firm which now proposes to supplement its Newcastle works by additional works at Walker Gate. Since Messrs. H. Watson & Sons, the well-known manufacturers of ships' pumps, feed-water filters, &c., removed part of their business to this centre some years ago, the growth of the place has been very rapid, and in many well informed quarters, it is considered probable that it will eventually become one of the main business centres of the district.

The engineering firms engaged in the manufacture of steamship accessories, are in nearly all instances very busy, and forging establishments have still as much work as they can deal with. In the iron foundries orders are plentiful, and the same may be said in reference to brass foundries and copper smithing works.

The engineering departments at the Elswick Works (Messrs. Armstrong, Whitworth & Co.), are very actively employed, and the operatives who were recently laid idle through the occurrence of a fire in the ordnance shops, are now nearly all re-engaged in other departments of the works. The restoration of the burnt-down shops is being rapidly proceeded with, as also are the extensions in other parts of the works.

Blyth.—The Blyth Shipbuilding Co. are at present very busy, all the berths being occupied with vessels in various stages of progress, while alongside the yard the s.s. *Somerford*, ordered by Messrs. Speeding, Marshall & Co., Sunderland, is receiving her equipment. Both the company's graving docks are occupied with vessels undergoing extensive repairs, and the graving docks of the Blyth Dry Dock Company are similarly engaged. At the coal shipping staithes business has been fairly active for some time past, and is likely to show further improvement.

THE WEAR.

(From our own Correspondent.)

Shipbuilding.—Through the visit of the naval architects to Sunderland one fact of importance has been elicited, namely that the north pier will be completed next year. The construction of the south pier (half of which has already been put down) will, it is certain, be delayed as little as possible, and it is quite within the bounds of probability that this new harbour of refuge on the north-east coast will be ready for use in three years from now. The other works of extension and development which the Wear Commissioners have in hand will be progressing meanwhile, and it is not too much to say that by the time the piers are completed the importance of Sunderland as a port will have become greatly enhanced. The improvement of the port will strengthen the hands of local shipbuilders, who, even with the disadvantage of a comparatively small water area for launching and mooring purposes, have kept pretty well up in the race of competition, and who may be trusted not to lag behind under the better conditions promised.

Messrs. J. L. Thompson & Sons, are now adding another large shed to their frame adjusting, and building department, and have ordered suitable machinery to equip it. This addition to the premises will doubtless (as it is intended to do) greatly facilitate the carrying out of contracts, and will ensure to the firm an additional means of outdistancing their competitors the matter of output. The firm are reported to have received an order for three large steamers from Messrs. Hogan, of Bristol, a firm for whom they have built many vessels, and to whom they must have given thorough satisfaction, if the placing of repeat orders may be taken as an indication. They have a large amount of other work in hand, and will have full need for all the additional facilities they are bringing into existence. The firms' Manor Quay repairing works are exceedingly busy, there being three important contracts in hand, while others it is stated are being arranged for. The yards of Messrs Blumer, and the Strand Shipbuilding Company are fairly busy the first-named firm having four vessels on the stocks, while at the last named establishment there is a good deal of repair work in hand in addition to the new work.

Sir James Laing & Sons have the building berths at their yards pretty fully occupied, several of the vessels in hand being of large size and of superior class. It is reported that the firm are negotiating for some new orders, but no definite particulars have as yet become known. The firm have just completed very extensive repairs to the oil carrying steamer *Le Coq*, which has been taken to the South Dock for "bunkering" &c., preparatory to going to sea.

Messrs. Robert Thompson & Sons have four vessels on the stocks and one in the water fitting out; while at Messrs. Doxford's and Messrs. Pickersgill's yards, there are five and three vessels respectively in process of building. Messrs. Priestman & Co. have an exceptionally large vessel in the plating stage, and one or two others in earlier stages; but the yard does not, on the whole, appear to be particularly busy.

Messrs. Short, Brothers, launched, early in the month, a fine vessel, 375 ft. long, ordered by the Southern S.S. Co., and have just delivered an equally fine steamer, if a little less in size, built to the order of Mr. James Knott, of the Prince line, Newcastle. Both these vessels are splendid specimens of the modern high-class cargo boat, and are not only a credit to the firm who turned them out, but also to the port in which they were produced. The firm have several other vessels of a special and superior class in progress, most of which, it is expected, will be placed in the water by the end of the year. It may be stated that the officials of the Boilermakers' Society have, for reasons best known to themselves, continued to annoy the firm with their attentions up to the middle of the month (July), the most objectionable of their tactics being the placing of pickets near the yard, to persuade men from seeking work there, and to entice (if possible) the men out who were at work. The Boilermakers' officials have, of course, no kind of excuse for doing this, as they have nothing whatever to do with the yard, and never had; but the utter want of success on the part of their pickets, either to entice men out or persuade men to keep away, has apparently had its effect, and the picketing has, we understand, now been discontinued. Meanwhile, the firm have an abundance of labour at their disposal, and are likely to have an exceptionally large output this year.

There is a good deal of repair work in the port just now, and all the graving docks are occupied with vessels, undergoing more or less extensive overhauls.

Engineering.—At the Palmer's Hill Works, business is very active, there being several repair and re-boilering contracts in hand in addition to the new work. The department in which Dickinson's patent crank shaft is manufactured is particularly brisk, and the demand for this speciality is well sustained. The extensions, which have been long talked of, are, it is reported, shortly to be undertaken, and will, it is supposed, be very comprehensive in character. At the Scotia Engine Works (Messrs. William Allan & Co.) a large vessel, has just been fitted with her machinery, and there are other vessels being fitted with their engines and boilers at Messrs. Doxford's and Messrs. Clarks'. The Sunderland Forge and Engineering Works still continue very busy, and it would be difficult to say which has most work —the electrical or the forging department. The Monkwearmouth Iron Works are kept well employed, and both iron and brass foundries have still a sufficiency of orders to keep them fully going. Manufacturers of patent anchors are kept very busy, principally on local orders.

The Hartlepools.—Shipbuilding shows no signs of falling off, both new and old work being still abundant. Engine works are also kept fully employed, and local steel works continue working full time.

Stockton.—At this centre shipbuilding continues brisk, the work in hand being sufficient to keep all berths occupied. The extensions at Messrs. Craig, Taylor & Co.'s Yard, which are well advanced towards completion, are of a most important character and will add very materially to the productive capacity of the yard.

Middlesbro'.—It is understood that Sir Raylton Dixon & Co., have booked an important order from a Hamburg firm, and as the firm have already several large contracts on their books, it is apparent that the existing briskness of the yard is sure to continue for some time to come. Engineering and boilermaking works still keep busy, while at the steel works the pressure of business is undiminished.

THE MERSEY.

(*From our own Correspondent.*)

ALTHOUGH here and there some falling-off as regards new work coming forward is reported in the shipbuilding and marine and general engineering trades of this district, the position generally is one of sustained activity. Machine-tool makers especially are exceedingly well engaged, and a good deal of overtime is being worked, whilst boiler makers, locomotive builders, and structural engineers continue fully employed. Evidence of the present brisk condition of trade is afforded by the numerous works extensions that are being pushed forward in various directions. In the Manchester district, besides the large new shops that are being erected by Sir W. Armstrong, Whitworth & Co., Limited, Messrs. Crossley Bros. are extending their establishment, and Messrs. B. & S. Massey are doubling the capacity of one of their erecting shops, and tool makers, textile machinists, and boiler makers in other Lancashire centres are carrying out similar enlargements. With the exceptional activity in trade, wages questions necessarily crop up in various centres. In Mid-Lancashire the employers have refused to concede an advance of 2s. asked for by the men and the men have threatened to strike. At Liverpool an advance of 6d. per week in local rates has been conceded, which makes an advance of 2s. since the strike.

The monthly returns issued by the trade union societies are again of a very satisfactory character. The Amalgamated Society of Engineers reports a slight increase in the number on out-of-work donation, which is now 2½ per cent. of the total membership, but this is largely due to the unfortunate fire at Sir W. Armstrong, Whitworth & Co.'s works at Elswick, which has thrown a considerable number of men out of employment, and it does not, of course, represent any falling-off in trade. Locally the number on benefit shows a further decrease, the proportion being less than 2½ per cent., and the district officials report considerable difficulty in supplying the demand for smiths, pattern makers' and fitters. In the Steam Engine Makers' Society there is only one per cent. of the total membership on benefit, whilst in the Lancashire centres practically a clean book is reported. The United Machine Workers' Association has now less than two per cent. of the total roll on benefit, and only 1⅓ per cent. in this district. At Salford, Hartlepool, Barrow, Stockton, Keighley, Bradford, Doncaster, Huddersfield, Blackburn, Ashton-under-Lyne, Crewe, Preston, Gloucester, Wigan, Woolwich, Erith, Hammersmith, Westwood, Loughborough, Grimsby, Attercliffe, and Liverpool, this organisation has no members receiving out-of work donation. Returns as to state of trade continue very favourable.

The British Westinghouse Electric and Manufacturing Co., Limited, which has been formed for the purpose of establishing works for the production of all descriptions of electrical machinery and plant, not only on a larger scale than any now existing in this country, but probably more extensive even than those at Pittsburg, have entered into arrangements with the Trafford Park Estates Co. for the purchase of 40 acres of land on the banks of the Manchester Ship Canal, and here, it is stated, works are to be erected, which will give employment to some 5,000 hands. This important industrial development may mean that Manchester will in the future become the centre for the manufacture of electrical appliances, whilst it will necessarily give an important impetus to the progress of the Ship Canal. Numerous other works are either in progress or in contemplation on the Trafford Park Estate, and amongst other firms Messrs. Morell & Mills, shipwrights; Messrs. W. H. Bailey & Co., engineers; W. T. Glover & Co., electrical engineers; the Lancashire Dynamo and Motor Co., and the Trafford Power and

Light Supply Co. have secured sites for works, which in some cases are already in course of erection.

The Ardwick Engineering Co., of Manchester, have a new design in quadruple-expansion engines for marine and other requirements where space is limited. This engine, which is made in sizes of from three to 25 H.P., has balanced cranks, and the feed, circulating, and air pumps are worked direct from the crossheads. It is of very compact design, and is made as light as possible consistent with strength. The company also make a special form of oil engine, the novel feature of which is that it can be converted, if desired, into a gas engine. When it is required to effect this change, all that is necessary is to disconnect the oil tank and vaporiser. The crank, which runs in oil, the connecting-rod, &c., are boxed in the column, an arrangement possessing obvious advantages in the way of compactness and cleanliness. The engine is strongly proportioned throughout, and all the working parts are of steel, so that the risk of breakdown is reduced to a minimum.

A new patent flux for strengthening cast-iron, steel, &c., is being manufactured by Messrs. James Evans & Co., of Salford, Manchester. By means of this composition, all descriptions of castings, "from piano frames to projectiles," can be strengthened from 10 to 25 per cent., according to the mixture and nature of the iron used. The flux is placed in the ladles which take the iron as it comes from the cupola, and is then stirred with a dry loamed rod, or if required, special apparatus can be supplied for feeding the flux with the blast. The action of the flux is immediately noticeable in the clear and exceptionally fluid state of the treated iron, and it is claimed that blow holes and other points of weakness are prevented, whilst no obnoxious fumes are emitted during its action. For strengthening a ton of iron about 20 to 25 lbs. of the composition are used. We have ourselves seen iron castings which, after treatment by this process, showed an increased strength of over 20 per cent., as compared with castings prepared in the same way, but with no admixture of the flux.

The London Fire Appliance Co., of Manchester, are supplying a very handy double-lid bucket, specially suitable for fire extinguishing requirements where a good deal of dust is continually floating in the atmosphere. The lid opens automatically on either side when the user is throwing the water, but when not in use, and with the handle in an upright position, the lid remains tightly closed, so that no dust can get in to thicken or suck up the water, whilst natural evaporation is largely prevented.

A continued strong advance in prices, with an increasing scarcity of supplies, has been the general report throughout the iron trade during the past month. Makers and manufacturers, in fact, have little or nothing to offer for anything like prompt delivery, their difficulty being to keep up supplies on account of contracts already in hand. In pig-iron there has been a general rise of 6s. to 10s. per ton, and on business put through, chiefly for deferred delivery, full prices have been got. Local makers are practically out of the market, and refusing to quote at all. Lincolnshire makers have put up their prices about 10s. per ton, and even at these rates are unable to promise early delivery; delivered Manchester 75s. 6d. for foundry net, and delivered Warrington 73s. 2d. for forge, are their quotations. Derbyshire foundry has risen to about 76s. 6d. net delivered here, with scarcely anything offering Middlesbrough is about 10s. dearer, and exceedingly difficult to obtain; for good foundry brands, by rail Manchester, 84s. net is the minimum rates. Scotch iron has advanced about 6s., 78s. to 78s. 6d. net being quoted for delivery Manchester Docks. There is little or no American pig-iron offering for present delivery, but there are quotations for supplies to come over with the October cotton shipments at 74s. net Manchester Docks, which represents a substantial rise on recent rates.

Finished-iron makers are exceedingly busy. In bars the home trade is exceptionally brisk, with producers considerably behindhand with deliveries, whilst the shipping business is unprecedented for this time of the year. Both Lancashire and North Staffordshire bars have been officially advanced another 10s. per ton, local makes being now quoted £8 5s. to £8 10s., and North Staffordshire £8 10s. as the minimum, delivered here. Sheets have risen about 15s., the price being now £9 10s. Hoops are in steady home request, with a heavier shipping demand than has been experienced for many years past; list rates have been put up 10s. per ton, random being £8 12s. 6d. and special cut engths £8 17s. 6d. delivered Manchester district and 2s. 6d. less for shipment. In wire rods something like a "famine" of supplies exists. Foreign competitors have practically withdrawn from the market, and English makers are quite full of orders, with prices stiff at £8 15s. to £9.

Nut and bolt makers have put up list rates 10s. to 20s., and iron and steel boiler tube makers have reduced discounts 2½ per cent, representing an average advance in prices of about 5 per cent.

Prices in the steel trade have also shown a strong upward move. Hematites are about 7s. higher, 87s. 6d. less 2½ being now the minimum for No. 3 foundry, with billets 5s. up, £6 2s. 6d. net cash being quoted, delivered here. Bars range from £7 15s. to £8 and upwards, and boiler plates are now £9. Steel hoops have been advanced 10s., £9 being the new rate, with makers full up right through the autumn, whllst sheets have risen to £10, delivered in this district.

The metal market continues active with prices hardening, but no change in list rates. Delivered Manchester district solid-drawn brass boiler tubes remain at 9d.; condenser tubes, 10½d.; copper tubes, 11½d.; brazed copper gas and steam tubes, 11¼d.; brazed brass tubes, 10d.; common rolled brass, 8¾d.; common brass wire, 8½d.; copper wire, 10¼d. per lb.

Timber has been in fair demand; although imports have been large, deliveries have fairly kept pace, and stocks have not increased unduly, whilst prices are without much change. Teak squares have been imported moderately; the demand is fair, and prices show some improvement, with stocks not heavy. Planks are in good request at steady rates. There are no arrivals of greenheart to report, but consumption has been light and stocks are heavy.

The coal trade shows no material change, all descriptions, except the better qualities for house-fire purposes, being in brisk request, with prices firm. In house coals some stock is going down, notwithstanding shorter time—about four days—is being worked at many of the pits, but this will be fully required for winter needs, and local collieries are holding to their list rates, although cheaper lots are on sale from outside districts. Steam and forge coals move away freely, with prices strong on the recent basis. Engine fuel is in active demand, and supplies are becoming increasingly scarce, collieries having a difficulty in keeping up deliveries, with the result that prices are hardening, slight advances being quoted on forward contracts. At the pit's mouth best Wigan Arley averages 11s. 6d. to 12s. 6d.; Pemberton four ft. and seconds Arley 10s. to 11s.; and common house coal 9s. to 9s. 6d.; steam and forge coal 8s. 9d. to 9s.; with engine fuel 6s. 6d. to 6s. 9d. for best; 5s. 6d. to 5s. 9d. for medium, and 4s. 9d. to 5s. for common slack.

Shipping is brisk in some quarters, but prices are without quotable change, ordinary steam coals averaging 9s. 6d. to 9s. 9d.; Garston Docks, 10s. to 10s. 3d. High level, Liverpool; and 10s. 3d. delivered Partington tips, Manchester Ship Canal.

THAMES.

(From our own Correspondent.)

Babcock & Wilcox.—Some trouble came over one of the tubes of a Babcock & Wilcox boiler in one of the merchant steamers, and in making his report of the tube the Board of Trade Inspector showed how it had got hurt. We do not remember that it was explained that this same tube had been plugged up, and, in that condition, and with no water in it, had been left to the mercy of the fire. It naturally got red hot and naturally bent into rather a fantastic shape. But this was not as a circulating medium of the boiler. A very important contribution to the matter has been made by Mr. Charles Wilson in a letter. He there gives an account of the behaviour of the Scotch boilers in the *Hero*, and also the behaviour of the water-tube boilers in their place. During the first six voyages of the vessel the average mean speed was 11·45 knots on a consumption of 178 tons of coal; and the average mean speed of the last six voyages with the Scotch boilers was 11·3 knots on a consumption of 163 tons. After that water-tube boilers were fitted in, when the mean speed on the same voyage was 12·75 knots on a consumption of 165 tons. When the lower tubes were examined at the end of the voyage they were found to be quite straight. These tubes were 1⅝ in. diameter and 7 ft. 6 in. long. The last voyage of the s.s. *Hero*, of the Wilson Line, showed a consumption of 17 cwt. per hour with an I.H.P. of 1364 and speed

12·78 knots. This is 1·39 lbs. of coal per I H.P. per hour. The boilers in the *Hero* are four years old, and she has never once been detained during that time for boiler repairs. Several tubes in the lower row have been renewed, but none of the upper ones have been taken out. The business of the firm in marine boilers is fairly brisk. Already ten war ships of the United States have been fitted with these boilers. The latest of these being the monitor *Wyoming*, the dimensions of the engines of which are

$$\frac{17\text{ in.} \times 26\tfrac{1}{4}\text{ in.} \times 40\text{ in.}}{24\text{ in.}}$$

It is a twin-screw-ship and four boilers have been fitted into her. The cruiser *Cincinatti* is the other later ship. She is of 5,000 I H.P., and she has eight Babcock & Wilcox boilers fitted into her. In the merchant service the latest notable orders are from the Steel Wire Co., which is having five of its steamers fitted with them. Each steamer is of 2,000 I.H.P. In this country Cook has four of his excursion steamers fitted with water-tube boilers for the trips on the Nile. The latest of these pleasure Nile steamers is the *Serapis*, built by Messrs. Alley & MacLellan, Glasgow. There is one boiler and the engines are 125 I.H.P. The names of the other three steamers are *Oonas* (one boiler, engines 125 I.H.P.), *Rameses* (two boilers, engines 375 I.H.P.), and *Mahomet* (one boiler, engines 125 I.H.P.). There has also been fitted lately into a ship for the Volga named the *Bernsa*, one boiler, fitted with apparatus for burning liquid fuel. Her engines are of 650 I.H.P. H.M.S. *Sheldrake* has just come home from another 1,000 miles trial, and no hitch has yet been reported. The consumption of coal is said to have been 1·56 lbs. per I.H.P. per hour.

Sturtevant Fan Co.—Fans made on the centrifugal force principle, can send air along pipes at considerable pressure. The highest pressure that can comfortably be reached with the Blackman fan is ¾ in. of water. The Sturtevant can go up to 25 in. of water. Such a fan is best suitable for fire blasts and cupola furnaces. These fans are made of different sizes and are known by numbers. No. 0, at 1½ in. of water, delivers 200 cubic feet per minute, and uses ·125 I H.P. to drive it. No. 4, when giving air at 1½ in. of water, delivers 400 cubic feet, and uses ·2 H.P. They are simply driven by counter shafting from the main shafting or by a steam engine and belts to the pulleys of the fan, or by an electric motor and counter shafting.

Messrs. Caird & Rayner.—The exhaust steam of the auxiliary engines in steamships for feed pumps, circulating pumps, generating electricity, compressing air, or forcing water is to be utilised by an invention of this firm for producing fresh water. Usually the steam used for evaporation is taken direct from the boilers or from a donkey boiler. Usually also, the exhaust from the auxiliaries for the above purposes is allowed to escape at considerable pressure. This firm provides a receptacle into which the exhaust of all the auxiliary engines is led, and from which the steam then passes to the evaporator. The receptacle is provided with a safety valve, and steam escaping by it is led to the main condenser. "The fresh-water condensing apparatus may be used for several purposes. The water resulting from the condensation of the exhaust steam being used as feed-water for the boilers, whilst that resulting from the condensation of the vapour generated by condensation of the exhaust steam may be used for drinking and culinary purposes or for feed make-up.

Messrs. Yarrow & Co.—This firm had the trial of a Japanese torpedo-boat destroyer, *Akebona*, one of six similar vessels ordered by the Japanese Government, and we are now in a position to give particulars. The type of engine is the four-cylinder triple expansion. The high-pressure cylinder is 20½ in.; intermediate pressure, 31½ in.; and the two low-pressure, 34 in. in diameter; the stroke being 18 in. They are twin-screw, and the engine balanced on the Yarrow, Schlick and Tweedy principle. There are four boilers. The engine can indicate 6,000 I.H.P., and the boilers can supply steam for 1,600 I.H.P. each. On April 24th she made a mean speed on trial of 31·159 knots. The boats are each 220 ft. long and 20 ft. 6 in. beam. They have four funnels and a conning tower, and the armament consists of one 12-pounder and five 6-pounder quick-firing guns, and two swivel tubes for 18 in. torpedoes. The expansion joint for steam pipes consists of dividing the pipe for a short length into two branches, arranged in the form of a square. The pipe by that is allowed to expand and contract, and it is taken up by a partial rotation in the pipe; the junctions are similar to those of a trunnion joint. There are two movements which these joints have to provide for, the expansion or contraction due to change of temperature, and the constant movement of the vessel, in rough water, the latter often being the more important of the two.

An important discussion took place in the House of Commons, on the motion of Mr. William Allan, on the Belleville boiler. A correspondent of the *Daily Chronicle* says that as the B Fleet at the naval manœuvres sailed past they could tell which were fitted with Bellville boilers by the quantity of smoke issuing from the funnels. Almost the first signal was, "Too much smoke." Mr. Goschen said the extra consumption was due to auxiliary machinery, electric lighting, &c. One point against the water-tube boiler is that they cannot use salt water, and within the first two days two cruisers were put out of action. It is said the Niclausse boiler will be introduced as a rival to the Belleville.

BELFAST.

(From our own Correspondent.)

VERY little falls to be reported this month in connection with the shipbuilding and engineering trades in Belfast, owing to the summer holidays occurring during the month, which cause a general slackening-down previous to the holidays themselves, and naturally the resumption of work is anything but prompt, so that the best part of the month is lost. Then, again, owing to the dearth of riveters, &c., the shipyard work has been seriously delayed.

Up to date we have had no launches. Messrs. Workman, Clark & Co , Limited, despatched the well-known Allan liner *Parisian* on July 13th. It will be remembered that early in the year this vessel was taken off her station in order to be thoroughly overhauled and to have new boilers fitted, whilst her engines have been converted into triple-expansion. The original engines in the vessel were, we understand, three crank compound, working at a pressure of 80 lbs. per square inch. Two of the cylinders, we believe, were removed, and suitable new ones fitted at a working pressure of 180 lbs., the steam being supplied from four large steel boilers. After adjustment of compasses and a successful trial in Belfast Lough, during which a speed of 15 knots was obtained, the steamer left direct for Liverpool, in order to load up and resume her former sailings.

On July 7th the s s. *Medic*, built by Messrs. Harland & Wolff, Limited, for the White Star Line, left her moorings in Abercorn Basin, and proceeded down the lough for adjustment of compasses and trial trip. The dimensions of the *Medic* are:—Length, 550 ft.; breadth of beam, 63 ft.; depth, 44 ft. She is of about 12,000 tons gross register, is propelled by twin screws, and her machinery has also been constructed in the builders' own works. The *Medic* is one of the fine new steamers intended for Messrs. Ismay, Imrie & Co.'s new service *via* the Cape from Liverpool to Australia, and her departure on August 3rd will be an important event in shipping circles. Practically in the past the port of communication from the United Kingdom for Australia has been London, so that in inaugurating this new steamship service from Liverpool, Messrs. Ismay, Imrie & Co. will be entering on an entirely fresh field of enterprise. The *Medic* and the other steamers for this service will be provided with accommodation for third-class passengers only, and as there will be no other class on board, the whole of the upper and best parts of the ship will be at their disposal; so that, except for the fact of the fare being simpler and the surroundings plainer, the passengers might be deemed to be travelling first-class. With electric light fitted throughout, immense cargo capacity, facilities for cooling and refrigeration, and all provisions necessary for the comfort of passengers on a long voyage—such as dining-room with separate revolving seats, reading-room, smoking-room, cabins for two or three as well as larger ones—the advent of the *Medic* and her sister ships on this trade promises to add to the popularity and fame of the White Star Line, and will bring our most distant colonies within the reach of those who are obliged to be mindful of economy in travelling. After a very satisfactory trip on the lough, the *Medic* left for Liverpool, with Captain Thornton in command.

Messrs. Harland & Wolff, Limited, have also just built and engined for Messrs. Frederick Leyland & Co., of Liverpool, the new twin-screw-steamer *Winifredian*, which ran a most successful trial trip on July 8th, and immediately after left for Liverpool. The *Winifredian* is intended for Messrs. Leyland's Atlantic service, and is of about 10,500 tons gross register, her length being 552 ft. by 59 ft. beam by 41 ft. deep. Excellent accommodation has been provided for a large number of passengers, whilst the deadweight capacity of the ship is very great. The arrangements for carrying cattle and horses, for the conveyance of which this line is now so well known in the Atlantic, are the very latest, and provision has been made for a large number. Refrigerating plant has also been fitted, as well as electric light throughout, and all appliances for loading and discharging cargo expeditiously and with economy.

Another notable event of the month has been the presentation of the freedom of the City of Belfast to Mr. Ismay, of the White Star Line. The idea originated with the Corporation some months ago, and on becoming known was received with great favour by all classes of the citizens, so much so that the individual subscription towards a casket for enclosing the certificate had to be limited, so as to allow a thoroughly representative list of citizens and artisans being made up. The presentation took place on July 20th in the council chamber, and was followed by a luncheon given by the Lord Mayor (Mr. Otto Jaffe), which was heartily enjoyed by all present. In this connection we may mention that it is officially announced that the s.s. *Oceanic* will be thrown open for public inspection on the 19th of August, and it is expected she will take her departure from this port about the 24th of this month.

NORTH-WEST OF ENGLAND.

(*From our own Correspondent.*)

Barrow.—There is still a very brisk trade in shipbuilding in this district, but builders have not lately increased their order sheets, because their hands are so full of contracts which there is pressing need to push along with. Apart from the *Vengeance*, first-class battleship, launched on the 25th of June, Messrs. Vickers, Sons & Maxim have on hand three first-class armoured cruisers and a torpedo-boat destroyer for the Admiralty, and a Japanese battleship of 15,000 tons. This is not as big a programme of work as Messrs. Vickers will ultimately be able to undertake, but at present their hands are full, for considerable attention was necessary to be devoted to the extensions which are going on in the yard every day, to the new machinery which is being put down in every department, and to the development of electricity and its substitution as motive power for steam. Considerable progress has been made during the month with the work in hand. Two launches have taken place —the *Vengeance* and the Pacific Steam Navigation Co.'s twin-screw-steamer *Ortona*, of 7,600 tons, the second largest merchant ship built at Barrow, the largest one being, of course, the *City of Rome*. The cruisers *Hogue* and *Euryalus* are gradually getting into frame, the *Hogue* being the farthest advanced, whilst the keel of the *King Alfred* has already been built up on the ways just vacated by the *Ortona*. At the present rate of progress it is expected that in under 12 months from now the *Hogue* and the *Euryalus* will be launched, whilst the Japanese battleship will doubtless soon follow them. The *King Alfred* is, of course, a very important cruiser, both as regards her size, her armour, and the speed she has to acquire. Naturally the Barrow company will aim to make her as big a success as the *Powerful*, and the latter has been a great success despite the rumours about her being as bad a job as the *Terrible*. It is said the latter is to go out to China to relieve the *Powerful*, and that the *Powerful* will, on coming home, have economisers added to her boilers. If this is done very great economy in coal consumption will be ensured.

Considerable interest has naturally been taken at Barrow in the operations of locally built cruisers in the Naval Manœuvres. The high terms in which the first-class cruiser *Niobe* has been extolled are only equalled by the encomiums passed on the second-class cruiser *Juno*, both built at Barrow, and both spoken of by experts as really good jobs.

Some interesting observations were made on the occasion of the launch of the Pacific Steam Navigation Co.'s steamer *Ortona*, launched at Barrow on July 10th. Mr. Shirley, in the course of his remarks, said he believed the Pacific Co. went as far back as 1841, and it had gone on improving ever since. They had at present 37 ships, and of these four were in the Australian trade, 20 were in the West Coast trade, and 13 were in the trade between Liverpool and West American ports. When first the company commenced its trade with South America they employed paddle-steamers. Little by little the trade grew, but it was felt to be impossible to employ steamers between Liverpool and Valparaiso until the late Mr. John Elder made a practical success of his arrangement for the compound engine. Then, and not till then, were they able to run steamers direct from Liverpool to the West Coast of South America. They had gone on improving since then, and when he looked back, he was perfectly surprised at the progress they had made during the last 40 years. He thought he might safely say that 40 years ago they were quite happy in steaming a ship of 1,000 tons deadweight at 10-knot speed at the consumption of one ton of coal per hour, or 24 tons per day. Now they could propel a ship of 5,000 or 6,000 tons on the same consumption of fuel. That meant a very great advance. The *Ortona* was not by any means the first vessel built for the company in Barrow. The Barrow Shipbuilding Co., in 1886, built for the company two steamships, the *Orizaba* and *Oroya*. These steamers were built for the Australian trade, and proved very successful, indeed extremely successful. That induced the company to give out orders to Barrow in 1899 for two other steamers, the *Oruba* and *Orotava*. The first two of these four vessels were still running, and he thought with the exception of the ordinary expenses in connection with machinery, there was nothing the matter with the ships or engines. He hoped the Pacific Co. would continue to prosper long after he and the present directors had gone, and that there would be no realisation of Macaulay's New Zealander sketching on the ruins of London Bridge the ruins of St. Paul's, but that on the contrary he would come to this country with a return ticket by the Pacific Line. Mr. Adamson, the director of Vickers, Sons and Maxim, who has the management of the Naval Construction Works, told the guests at the launch that as far as he was personally concerned, his first connection with the Pacific Co. did not carry him back to 1841, but he could go back a very long way. The first job he got when he went to Messrs. John Elder's works was to trace a drawing of the *Talca* in 1862, a paddle ship built for the Pacific Co., and he designed the first ship for the company to cross from Liverpool to Valparaiso, the *Magellan*. Since that time he had to do with 20 or 30 vessels built for that company. When he left the Clyde he lost connection with the company, but picked them up again when he came to Barrow. He hoped now they had got in touch again they would keep building for the company when they wanted ships. With the exception of the *City of Rome*, the *Ortona* was the largest merchant vessel ever launched from the Barrow yard. Lloyd's Committee visited Barrow on the occasion of the launch of the *Ortona* and were entertained by Messrs. Vickers, Sons & Maxim. Mr. James Dunn, a director of Vickers, Sons & Maxim, and late of the Admiralty, said he felt that he could speak for a very long time on the merits of this committee, but as he happened to be a member of the technical branch of that committee, he was precluded from uttering eulogiums, to which they were so fully entitled, but he ventured to say on behalf of the firm of Vicker's, that at no place would they receive a more cordial welcome than at Barrow. They were especially pleased to see them, and he had especial pleasure in seeing amongst them several who worked with him on the load-line enquiry including the chairman, vice chairman, and Mr. Martell, the chief surveyor of Lloyd's. Mr. Glover, the chairman of Lloyd's Committee, remarked that the committee invented a sort of ideal, and they did their best to enforce it. They had on this outing travelled to Cardiff, Newport, Swansea, Liverpool, Belfast, and Barrow, and from the commencement of their journey to its close they had seen nothing but enterprise, energy, progress, intelligence, and determination to excel in every direction, and what more could they expect from a community engaged in that particular branch of industry than those qualities. They were the qualities of manhood, and of enterprise, of which they had so good an example in their chairman that day. The ship *Ortona* would give example of the industry, energy, and enterprise of the 19th century, and would help to show such progress as would form a magnificent foundation for the further progress expected from England in the century that was to come.

We have frequently written about the great scarcity of house accommodation at Barrow, and a month or two ago reported the fact that Messrs. Vickers, Sons & Maxim had decided to build a thousand workmen's houses on Walney Island within a mile of their works. They have actually commenced with the work, which will be pushed on with all speed, but there is an immediate pressing demand for houses, and with a view to bridging over the temporary difficulty, Messrs. Vickers have purchased the old Guion Line steamer *Alaska*, the famous "greyhound of the Atlantic," which will be moored in the Devonshire Dock at Barrow, and utilised as a home for 400 to 500 workmen employed at the shipyard. A gangway will be thrown from the ship to the shore, and the men will live aboard as in a club, being provided for by stewards who will cook their food and otherwise attend to their comfort. The idea, novel most certainly, has caught on with the men and is likely to be popular. The cost of living on board will be small, because no profits will be charged, and as long as the necessary expenses are found the firm will not trouble. The management of the ship will be be placed in the hands of a committee elected by and of the men. This is perhaps the first instance on record in which a large shipbuilding company has found it necessary to house a large number of its workmen in a temporary floating house until permanent accommodation is provided. It is understood the ship will have fulfilled her purpose as a home for workmen in 12 months from now, when the new houses on Walney Island are expected to be ready for occupancy; but when these thousand houses are ready, another difficulty will arise as to the means of crossing Walney Channel. A bridge is absolutely necessary, for a thousand workmen rushing off to their dinner at one time cannot possibly be dealt with in the ordinary ferry boats. That question is now being considered, but from a present view of the question, a bridge is the only means of dealing with the difficulty.

Another large slice of land, several acres in extent, has been acquired by Messrs. Vickers, Sons & Maxim for the extension of the engineering and boilermaking department of their yard. New iron and steel casting shops are needed, together with other departments calculated to make the works a complete whole, and self-resourceful.

The installation of electric motors for the purpose of driving all sorts of machinery is going on apace at the Barrow Yard. The change is found to be most economical, very convenient, and capable of dealing with a fuller programme of work. Not only is electricity being utilised in the engineering department, but in the ship department as well. The way in which electrically driven punching machines are worked even when dealing with the heaviest of plates is marvellous. Further extensions in the use of electric motors may be looked for.

Arrangements are in progress for commencing work at the docks in the deepening of the sill of the Ramsden Dock by six feet. The work has been entrusted to Messrs. John Aird & Co., the well-known contractors, and they are at present engaged in getting their plant and tools ready so that the work can be started when the *Vengeance* is docked and the s.s. *Ortona* is finished and ready for sea. When these ships are placed, one into the docks and the other cleared of the docks, the entrance to Ramsden Dock will be closed for about ten months for the necessary alterations. Accommodation is being provided specially for the 400 men who will be employed on this job on Barrow Ramsay Island. The entrance basin of Ramsden Dock will be used as usual for heavy tonnage shipping and the entrance to the Devonshire Dock will be used for lighter craft.

The torpedo-boat destroyer *Otter*, one of the four 30-knotters built at Barrow, has successfully passed her official trials, and will be forthwith delivered to the Admiralty. The torpedo-boat destroyer now building at Barrow for the Admiralty will also be a 30-knotter. She will be named the *Vixen*.

West Cumberland.—There is a very brisk and steady business in the West Cumberland district, and shipbuilders are likely to be well off for orders for some time to come. The yards at Workington and Maryport are now engaged on a number of light craft ships, which will be followed by others as soon as the slipways are clear.

Shipbuilding Material.—There is a very brisk demand for shipbuilding material, and the steel mills in the district are fully employed, and likely to be so for a considerable time to come, on the contracts already in hand. Prices have advanced on the month, and are now quoted at £7 10s. for ship plates, and £8 12s. 6d. for boiler plates. All other classes of steel are in considerable request, and the outlook is a decidedly good one.

Hematites.—The Hematite pig-iron trade is very busy, and the fact that the demand is so much greater than the supply has run up prices considerably. Mixed Bessemer numbers are quoted at 80s. per ton net f.o.b. and warrant iron is at about the same value. Stocks have been further increased and now stand at more than 240,000 tons in warrant stores. Makers hold practically no stocks at all.

Shipping.—The shipping trade is busy, but the exports compare unfavourably with the returns for last year up to the same period. There are expectations, however, of big shipments during the remainder of the season.

OBITUARY.

Edwin Blackburn.

It is with regret that we have to announce the death of Mr. Edwin Blackburn, of Carlton Mount, Higher Tranmere, Liverpool, who was for about thirty years past the head engine draughtsman to Messrs. Laird Brothers, he was taken ill about three months ago, with bronchitis and throat trouble, but recently he seemed to rally somewhat. On Sunday afternoon, July 16th, he suffered a relapse, and passed peacefully away shortly before five o'clock. He leaves a widow, five daughters, and four sons, three of the latter being abroad. Mr. Blackburn, whose name and work were known throughout the engineering world, served his apprenticeship at Messrs. Fawcett. Preston & Co.'s, Liverpool, and in 1860 came from that firm to the drawing office at Messrs. Laird's, of which he was appointed chief over thirty years ago, serving in that responsible position until the time of his last illness. He was largely instrumental under Mr. R. R. Bevis, engineering manager, in securing for the Birkenhead Ironworks their great reputation as designers of effective engines. In the engineering world Mr. Blackburn's work was widely known, and it was thoroughly respected by all firms entering into competition with Messrs. Laird Brothers. He was thoroughly wrapped up in his profession; and his mind was a perfect storehouse of engineering statistics, and, indeed, he could enumerate practically every "job" he had turned out for the last forty years, with the areas, pressures, piston strokes, and an infinity of detail relating to each of them. On July 18th at Bebington Cemetery, Liverpool, the body was laid to rest, in the presence of a large company of mourners. He was well-known in Tranmere, where he had resided for so long, and out of respect to his memory, blinds were drawn and shutters closed along the route taken by the cortège.

Miscellaneous.

Three in One Oil.—Under the above comprehensive title the South British Trading Co., Limited, of 6, Victoria Avenue, Bishopsgate Street Without, London, E.C., are placing upon the English market an oil, which has been used in America with marked success for many years past. As its title implies, it has three useful functions, viz., it will clean, prevent rust, and lubricate. It appears to be capable of removing sticky and gritty substances from surfaces to be cleaned. It will prevent rust forming on iron and steel work from exposure to sea air, rain, dampness, or mud, therefore it is viscous enough not to run off and will not evaporate, but thoroughly cover and enter the pores of the material. In acting as a lubricant it has sufficient body to prevent its being forced out from between the surfaces to be lubricated. It is particularly applicable for firearms and other iron and steel instruments. As evidence of its utility we have seen copies of testimonials from Colonel Cody (the renowned Buffalo Bill) and Colonel Roosevelt, the governor of New York State, both of whom speak very highly as to its qualities as the result of practical experience.

Nunn, Ridsdale & Co.—The nautical and general lamp, and ship fitters' business of Ridsdale & Co., lately carried on at 54, Minories, has been purchased by the well-known firm of Messrs. W. & A. Nunn, of Shadwell. They have taken into partnership Mr. G. H. Gibson, who was for many years with the late firm, and will in future be known as Nunn, Ridsdale & Co., of 54, Minories, with works at Shadwell—manufacturers of every description of ship's lamps, lanterns, fog horns, ship fittings, Holmes rescue and distress signals, Colomb's flashing signals, and Robertson's patent boat rowlocks, &c.

LAUNCHES AND TRIAL TRIPS.

LAUNCHES—English.

Mavisbrook.—On June 6th Messrs. William Gray & Co., Limited, launched the handsome steel screw-steamer, *Mavisbrook*, built to the order of Messrs. Miller & Richards, of Glasgow. The vessel will take Lloyd's highest class, and her dimensions are:—Length, overall, 300 ft.; breadth, 42 ft.; and depth 21 ft. 9 in. The deck erections consist of a poop, bridge, and forecastle, with tasteful saloon and cabins for officers, &c., in the poop. The engineer's rooms are in the bridge, and the crew's accommodation forward. The hull is built with deep bulk angle frames, and a cellular double bottom and aft peak tank; five steam winches, steam-steering gear amidships, hand screw-gear aft, horizontal donkey boiler, steam windlass, boats on beams overhead, grain divisions, stockless anchors, two telescoping masts, and a complete outfit provided for a first-class cargo vessel. The Central Marine Engine Works of Messrs. W. Gray & Co., Limited, supply their triple-expansion engines, having cylinders 21½ in., 35 in., and 58 in. diameter, with a 39 in. piston stroke, and two large steel boilers to work at 160 lbs. pressure per square inch. The ceremony of naming the steamer *Mavisbrook* was gracefully performed by Mrs. Miller, wife of the managing owner.

Verulam.—On June 24th there was launched by Messrs. S. P. Austin & Son, Limited, at Sunderland, the steel screw-steamer *Verulam*, constructed under special survey at Lloyd's for 100 A1 class, and of the following dimensions:—Length, 268 ft.; breadth, 37 ft. 9 in.; depth, moulded, 19 ft. 9 in. Messrs. John Dickinson & Sons, Limited, are supplying the machinery.

Algores.—On June 24th there was launched at Maryport, for Messrs. R. Penny & Sons, of Shoreham, a steel schooner-rigged steamer of about 375 tons gross, named the *Algores*.

Clan Farquhar.—On June 24th there was successfully launched from the shipbuilding yard of Messrs. Doxford & Sons, Limited, the turret-ship *Clan Farquhar*, the ninth vessel of this type built by the firm for the Clan Line Steamers, Limited, Glasgow (Messrs. Cayzer, Irvine & Co.), and the 51st turret steamer now afloat. Her dimensions are: 440 ft. long by 51 ft. 6 in., and 32 ft. moulded, and she has a deadweight capacity of 8,400 tons. Her engines are: 27½ in., 45½ in., 75 in., and 60 ft. stroke, and have also been built by Messrs. Doxford & Sons. The *Clan Farquhar* was constructed under the British Corporation Survey, highest class.

Grosmont.—On June 26th Messrs. Ropner & Son, Stockton-on-Tees, launched a steel screw-steamer of the following dimensions, viz.:—Length, between perpendiculars, 325 ft.; breadth extreme, 46 ft.; depth, moulded, 24 ft. 9 in. This steamer, which has very fine lines, and is a very handsome vessel of her type, has been built to the order of Messrs. Gladstone & Co., West Hartlepool, off the three-decked rule, having full poop, long bridge, and top-gallant forecastle. The saloon and cabins for the captain and officers will be fitted up in the poop, and the accommodation for engineers will be provided in iron houses on the bridge deck, the crew being berthed in the forecastle as usual. She has double bottom on the cellular principle for water ballast, and has been designed to carry a deadweight cargo of about 4,850 tons on Lloyd's summer freeboard on a light draught of water. She will have all the most recent appliances for the expeditious loading and unloading of cargoes, has direct steam capstan windlass, steam-steering gear amidships, with powerful screw-gear aft, four large steam winches, multitubular donkey boiler, stockless anchors, &c. This is the fourth steamer built by Messrs. Ropner & Son for the same owners. She will be fitted with a set of triple expansion engines by Messrs. Blair & Co., Limited, working at a pressure of 210 lbs. The christening ceremony was gracefully performed by Miss Isabel Rudd, of Ivy Croft, Stockton-on-Tees, who gave her the name of *Grosmont*.

Vinolia.—On June 27th Messrs. Cochrane & Cooper, Limited, launched from their Grovehill Shipyard, Beverley, a new steam trawler—of the following dimensions: 112 ft. by 21 ft. by 11 ft. 6 in., depth of hold—built to the order of the Arctic Steam Fishing Co., Limited, Grimsby. Messrs. C. D. Holmes & Co., of Hull, are supplying triple-expansion engines, and the vessel will be complete with all modern appliances for trawling. Miss Bates, of Grimsby, named the vessel the *Vinolia*, and after the ceremony the company adjourned to the offices of the builders for luncheon.

Atlantian.—On June 27th Sir W. G. Armstrong, Whitworth & Co. launched from their Walker Shipyard a large steamer of the following dimensions, viz.:—Length, 500 ft.; breadth, 57 ft.; depth, moulded, 43 ft. 9 in., with a deadweight carrying capacity of about 11,500 tons. She has been constructed of steel, in accordance with Lloyd's rules for their 100 A1 class, the Board of Trade passenger regulations, and the American law. The vessel is of the twin-screw type, and has been built to the order of the West India and Pacific Steamship Co., Limited, of Liverpool. The vessel will be fitted with twin-screw triple-expansion machinery by the Wallsend Slipway and Engineering Co., Limited. The vessel was named *Atlantian* by Mrs. Stitt, wife of Mr. J. Carlton Stitt, one of the managing directors of the company.

Somerford.—On June 28th there was launched from the Shipbuilding and Repairing Works of the Blyth Shipbuilding Co., Limited, of Blyth, a steel screw-steamer for Messrs. Speeding, Marshall & Co., of Sunderland. The dimensions of this vessel are:—Length, 282 ft.; breadth, 40 ft. 9 in.; and a depth of 20 ft. 6 in. The vessel is built to secure Lloyd's 100 A1 class, and is on the single-deck principle with deep frames. The cabin accommodation is fitted on top of bridge amidships; the officers' and engineers' berths are under the bridge, and the crew in forecastle. Triple-expansion engines of good power will be supplied and fitted by Messrs. MacColl & Pollock, of Sunderland. As the vessel left the ways, the ceremony of naming her *Somerford* was gracefully performed by Miss Marshall, daughter of one of the managing owners. After the launch the company adjourned to the builders' luncheon room, where the usual toasts were proposed and duly acknowledged.

Steam Launch.—On June 29th there was launched from the shipyard of the Lytham Shipbuilding and Engineering Co. a twin-screw steam launch, built of galvanised steel to the order of the Egyptian Delta Light Railways Co., of London, and is specially designed for towage service, &c., on the Nile Delta, by Messrs. Flannery, Tritton & Given, who have also superintended the construction of the vessel and her machinery, the special features being high speed on exceedingly light draught of water. The vessel is intended not only to carry cargo and passengers in connection with the railway system in Upper Egypt, but is also fitted for towing barges of suitable character for the conveyance of produce and native passengers. Experience has shown that the Nile lends itself specially for economical towage in combination with light draught, and very considerable developments of this trade are expected in the near future.

Bath City.—On July 6th there was launched from the North Sands Shipbuilding Yard of Messrs. Joseph L. Thompson & Sons, Limited, Sunderland, a finely modelled steel screw cattle and cargo steamer, named the *Bath City*, which has been specially built to the order of Messrs. Charles Hill & Sons, and is intended for their Bristol City Line to New York. She is of the following dimensions:—Length, between perpendiculars, 310 ft.; breadth, extreme, 40 ft. 6 in.; and depth, moulded, 26 ft. She is built on Lloyd's three-deck rule for the 100 A1 class, with a poop, bridge, and topgallant forecastle. She has two complete decks, water-ballast right fore and aft in the double-bottom and also in the after peak. The accommodation for the captain, officers, saloon passengers' berths, &c., is fitted in the poop aft. The engineers and petty officers are berthed in the fore end of the bridge, and the crew and firemen in the topgallant forecastle. The cattlemen's berths are fitted under the bridge. The deck machinery is of a powerful description, and consists of eight steam winches for the cargo hatches, each hatch being worked by double derricks. A steam windlass is fitted on the forecastle head, and steam-steering gear is fitted in a large wheel-house, and a screw-gear on the poop deck. The deck machinery is supplied with steam from a large donkey boiler. The vessel is rigged as a two-masted fore-and-aft schooner with five sails, and has awnings fitted in way of all accommodation. Four large boats are fitted on the bridge deck. The vessel is divided by the usual watertight bulkheads carried up to the weather deck. Shifting boards are fitted throughout the holds and 'tween decks. The poop and bridge, and bridge and forecastle are connected by strongly constructed gangway bridges. At each side of the vessel large gangway doors are constructed in the bulwarks, in way of the cargo hatches. A large steel chart and wheel-house is fitted on top of the bridge at the fore end, and over this is constructed the usual flying bridge. On top of the poop a large entrance house has been constructed. Patent stockless anchors are fitted, and a large fresh-water condenser. The vessel throughout is fitted as a first-class cattle and cargo steamer, with all the latest improvements for the rapid loading and discharging of cargoes. The machinery has been constructed by Messrs. Blair & Co., Limited, of Stockton-on-Tees, the sizes of the cylinders being 24 in., 40 in., 66 in. by 45 in. stroke, supplied with steam by two large multitubular boilers working at 160 lbs. pressure. The shafting is considerably in excess of Lloyd's requirements, and the engines have been built to a very complete specification. As the vessel left the ways the christening ceremony was gracefully performed by Miss Dora M. Jones, daughter of Captain Richard Jones, who will take command, and who is superintending the completion of the vessel which has been chiefly constructed under the superintendence of Mr. James Bailey, of Bristol. There was a large company present at the launch, which was effected by hydraulic power. The usual adjournment was made to the builders' luncheon room, where suitable toasts were duly honoured.

Lord Ormonde.—On July 8th Messrs. Dobson & Co. launched at Walker-on-Tyne a steel screw-steamer for the Irish Shipowners' Co., Limited, of which Messrs. Thomas Dixon & Sons, Belfast, are the managers. The dimensions of the vessel are:—Length, overall, 372 ft.; breadth, 46 ft. 3 in.; depth, moulded, 29 ft. 10½ in. She is built to Lloyd's highest class as a spar-deck vessel. The propelling machinery has been constructed by Messrs. John Dickinson & Sons, Limited, of Sunderland, and consists of a set of triple-expansion engines, having cylinders 24 in., 40 in., and 64 in., by 48 in. stroke. The vessel was christened *Lord Ormonde* by Miss Rosa Magill.

North Sea—On July 10th Messrs. Craig, Taylor & Co., launched from their shipbuilding yard at Thornaby-on-Tees, a steel screw steamer of the following dimensions, viz., 278 ft. by 40 ft. 8 in., by 20 ft. 6 in. moulded. She is built of steel to the highest class in Lloyd's under special survey, and is of the single-deck type, with poop, bridge, and forecastle; water ballast in double bottom fore and aft, and in peak; she is on the deep frame principle, and has large clear holds, and large hatches. She will carry about 3,000 tons deadweight on a light draught of water, and is fitted with patent steam windlass, patent steam-steering gear, four large steam winches, Meredith donkey boiler, screw-gear aft, telescopic mast to Manchester Canal requirements, and all the latest improvements. The propelling machinery has been constructed by Messrs. Thomas Richardson & Sons, Limited, Hartlepool, the cylinders being 21 in., 35 in., 57 in., by 39 in. stroke, two large boilers 160 lbs. pressure. This vessel has been built to the order of Messrs. Sanders, Wake & Co., London, under the superintendence of Mr. W. C. Carter, of 30, Great St. Helens, London. As she left the ways, she was gracefully christened the *North Sea* by Miss Wake, of London.

Petunia.—On July 10th Messrs. Cochrane & Cooper, Limited, launched from their yard at Selby a new steam trawler of the following dimensions, 115 ft. by 21 ft. 6 in. by 11 ft. 6 in., built to the order of the North-Eastern Steam Fishing Co., Grimsby. Engines of triple-expansion type are being supplied by Messrs. C. D. Holmes & Co., of Hull, and the vessel will be completed with all the most modern appliances for trawling. As the vessel left the ways she was christened the s.s. *Petunia* by Miss Alice A. Allen.

South Australia.—On July 10th this large and handsomely modelled steel screw-steamer—built for the Australian trade to the order of the Southern Steam Shipping Co., Limited, of London, of which Messrs. Lawther, Latta & Co. are the managers—was launched from the works of Messrs. Short Bros., Sunderland. This vessel, which is constructed of steel throughout, has been built under special survey to the highest class in Lloyd's register, and is of the following dimensions:—Length, 370 ft.; breadth, 48 ft.; and depth, moulded, 30 ft., with a large deadweight and carrying capacity, and has a continuous permanent shade-deck extending from forecastle to poop. Large and commodious deck-houses are fitted amidships on shade-deck for the accommodation of captain, officers, and engineers, with large and handsomely fitted saloons, the panelling being in polished hardwoods tastefully arranged. On the flying bridge deck a large and commodious teak wheel and chart house is fitted, the steam-steering gear is fitted in the engine-room with controlling rods to wheel house and flying bridge. The crew are berthed in the forecastle, which is divided by a passage-way, and further divided for petty officers, &c. The double-bottom is constructed on the cellular system, subdivided into trimming tanks, the peaks also being fitted for water ballast. The holds are four in number, which for rapid loading and discharging have been fitted with eight powerful steam winches, steam for which is supplied by a large multitubular donkey boiler placed in the stokehold. In addition, the vessel is fitted with all the newest appliances for despatch, and the economical handling of cargoes. A complete installation of electric light is also fitted. On leaving the ways the vessel was named *South Australia*, the ceremony being performed by Miss Dora T. Short, of Sea View, who was handed a very handsome present by one of the directors on behalf of the company. The vessel is to be fitted with triple-expansion engines by Messrs. Blair & Co., Limited, of Stockton-on-Tees, having cylinders 26 in., 42 in., and 70 in., with a stroke of 48 in., and two large steel boilers of 180 lbs. working pressure, fitted with Howden's system of forced draught.

Ortona.—On July 10th Messrs. Vickers, Sons and Maxim, Limited, launched at Barrow a large twin-screw steamer for the Australian mail and passenger service of the Pacific Steam Navigation Co. Miss Rankin, daughter of one of the directors of the Pacific Co., named the vessel *Ortona*. The steamer is 500 ft. long, 55 ft. beam. and 37 ft. moulded depth to upper deck, her gross tonnage being 7,600 tons. The hull is constructed of steel on the cellular double-bottom principle, and completed throughout to Board of Trade requirements. The vessel, as is the case with all the other steamers of the company, is not classed, but her scantlings are sconsiderably in excess of Lloyd's requirements. There are three complete closed-in decks, and accommodation is provided for 130 first, 162 second class, and 300 steerage passengers The machinery has been designed to give the vessel an average speed at sea when fully laden of 15½ knots. The propelling machinery consists of two sets of inverted, vertical, direct-acting, triple-expansion engines, each set having three cylinders working on separate cranks. The cylinders are:—High pressure, 30 in. diameter; intermediate pressure, 50 in. diameter: low pressure, 83 in. diameter; and the stroke 54in. The steam distribution valves are of the piston type for high pressure and intermediate pressure cylinders, and the flat double-ported description for low pressure cylinders. They are actuated by valve gear of the ordinary, double eccentric, link motion type, the reversing gear is of the "all round" type, with steam and hand-starting gear. The condensers are cast with back columns of main engines, and are supplied with circulating water from two centrifugal pumping engines. The auxiliaries in the engine-rooms consist of one large duplex ballast pump, one fire engine, two direct-acting main feed pumps, and one auxiliary feed pump, two evaporators, and one auxiliary condenser for taking exhaust steam from all auxiliary engines throughout the ship. The engines are supplied with steam from four double-ended boilers of the marine multitubular type, each fitted with eight furnaces, and worked under Howden's system of forced draught. The boilers are constructed for a working pressure of 190 lbs. per square in., to Board of Trade requirements. A large auxiliary boiler of the cylindrical type is also fitted for supplying steam to all auxiliary engines. The ashes are discharged overboard by means of silent hydraulic ejectors, one being fitted in each stokehole. The machinery throughout has been under the supervision of Mr. James Thomson, superintendent engineer of the Pacific Co., the resident inspector for hull and machinery being Mr. Hugh Brown.

Rollo.—On July 11th Messrs. Cochrane & Cooper, Limited, launched from their Grovehill Shipyard, Beverley, a new steam trawler of the following dimensions, 100 ft. by 21 ft. by 11 ft. depth of hold, built to the order of Mr. G. F. Sleight, Grimsby. Engines of triple-expansion type are being supplied by Messrs. C. D. Holmes & Co., of Hull, and the vessel will be completed with all the most modern appliances for trawling. Miss Gladys Sleight named the vessel the s.s. *Rollo*.

Ferndene.—On July 11th the Northumberland Shipbuilding Co., Limited, launched, at Howdon-on-Tyne, a large steel steamer built to the order of Messrs. J. T. Lunn & Co., Newcastle, for the Dene Line. The vessel will take the highest class under Lloyd's survey, and is 352 ft. long by 48 ft. beam, by 28½ ft. depth moulded. The steamer will carry a deadweight cargo of 6,300 tons. Messrs. Thomas Richardson & Sons, Limited, of Hartlepool, will supply the machinery, which consists of a set of triple-expansion engines, having cylinders of 24 in., 40 in., and 66 in. diameter, with a stroke of 45 in., supplied with steam by two large single-ended boilers, working at a pressure of 180 lbs. The steamer was named *Ferndene* by Miss Edith Lunn, daughter of the managing director of the Dene Line.

British Princess.—On July 11th the Palmer's Shipbuilding and Iron Co., Limited, launched from their Jarrow yard a finely modelled steel twin-screw-steamer of the following dimensions:—Length (between perpendiculars), 470 ft; breadth extreme, 56 ft. 6 in.; depth moulded, 35 ft., constructed for the British Shipowners' Co., Liverpool. The vessel will be rigged as a four-masted fore-and-aft schooner, and has been built under special survey to take the highest class in Lloyd's registry. She is of the three-decked type, with two steel decks laid all fore and aft, and has a closed-in shelter deck specially strengthened for the Atlantic trade, extending over the whole length, and above this a shade deck covering the machinery openings. All the available space under the shelter and shade decks is left clear for carrying horses. The vessel is designed to carry upwards of 10,000 tons deadweight on about 27 ft. mean draught. The engines, which are also being constructed by the Palmer Co. are of the triple-expansion twin screw type, with cylinders 26 in., 43 in. and 71 in. diameter by 48 in. stroke, steam being supplied by two double-ended boilers and two single-ended boilers with a working pressure of 190 lbs. On leaving the ways she was named *British Princess* by Mrs. Beazley, wife of Mr. Edwin Beazley, one of the managers of the British Shipowners' Co.

Drumbain.—On Tuesday, July 11th, Messrs. W. Gray & Co., Limited, launched a fine large steel screw-steamer, which they have built to the order of Messrs. W. Christie & Co., of London. She will take Lloyd's highest class, and is of the following dimensions, viz.:—Length over all, 336 ft.; breadth, 48 ft. 6 in.; and depth, 24 ft. The deck erections consist of poop, long bridge, and forecastle. The saloon and captain's and officers' rooms will be fitted in the poop. The hull is built with deep frames and cellular double bottom and aft peak tank for water ballast, five steam winches, steam-steering gear amidships, hand screw-gear aft, patent direct steam windlass, patent donkey boiler, grain divisions, stockless anchors; and a complete outfit will be fitted for a first-class cargo boat. Three cylinder triple-expansion engines of first-class make are being supplied by the Central Marine Engine Works of Messrs. W. Gray & Co., Limited. They will develop over 1,200 H.P. The cylinders are 24 in., 38 in., and 64 in. diameter, with a piston stroke of 42 in., and large steel boilers to work at a pressure of 160 lbs. per square inch. The ceremony of christening the steamer *Drumbain* was gracefully performed by Miss Florrie Mudd, of Hartlepool.

Hydra.—On July 19th Messrs. Wood, Skinner & Co., Limited, successfully launched from their shipbuilding yard, at Bill Quay, Newcastle-on-Tyne, a handsome new steel screw-steamer, which has been built to the order of Messrs. Bruusgaard, Kiosterud & Co., of Drammen, Norway. The vessel is a sister ship of the s.s. *Hugin*, recently built by that company for the same owners. She is of the improved single-deck type, with bridge and topgallant forecastle, and her principal dimensions are as follow, viz.: Length, 248 ft.; breadth, 35 ft.; depth, moulded, 20 ft. 6 in The vessel will be fitted with a set of engines of the improved triple-expansion type, having cylinders 18½ in., 30 in., and 49 in. diameter respectively, with a stroke of 33 in., supplied with steam from a large steel multitubular boiler working at 160 lbs. pressure per square inch. The engines and boiler have been constructed and will be fitted by the North Eastern Marine Engineering Co., Limited, at the Northumberland Engine Works, Wallsend-on-Tyne. Both the vessel and engines have been built to the highest class, viz., 1 A1* Norwegian Veritas, and have been surveyed during construction by Mr. Lauritz M. Bodin, of Sunderland, the local representative, and also superintended by Mr. Norman Burnett, of Newcastle-on-Tyne, on behalf of the owners. She will be rigged as a fore-and-aft schooner, and fitted with telescopic topmasts, as also with all the latest improvements and appliances in the way of deck machinery, for facilitating the rapid loading and discharging of cargo and general working and navigating. As the vessel left the ways she was christened *Hydra* by Mrs. Gabrielle, wife of Captain Gabrielle, of Christiania, Norway, who will command the steamer when completed and ready for sea. The *Hydra* is the fifth vessel constructed by the builders for Messrs. Bruusgaard, Kiosterud & Co.

Newton Hall.—On July 20th this finely modelled steel screw-steamer was launched by Messrs. Joseph L. Thompson & Sons, Limited, of the North Sands Shipbuilding Yard, Sunderland. She has been built to the order of Messrs. C. G. Dunn & Co., of Liverpool. The principal dimensions of the vessel are:—Length over-all, 379 ft. 6 in.; breadth, extreme, 49 ft. 6 in.; and depth, moulded, 29 ft. 6½ in. The vessel is built on the spar-deck rules to Lloyd's 100 A1 class, under their special survey, and is a fine example of the modern cargo vessel, with all the latest improvements and requirements for the owners' special trade. Water ballast is carried in a cellular double bottom, right fore and aft, and also in the after peak. The accommodation for the saloon, captain, officers, and also spare berths for the accommodation of a limited number of passengers, is placed at the fore end of the bridge, and for the engineers in sidehouses at the after end of the bridge. The crew, firemen, apprentices, and petty officers are berthed in the topgallant forecastle. The vessel is rigged as a two-masted fore-and-aft schooner, with telescopic topmasts to suit the Manchester Ship Canal. A large house is placed at the fore end of the bridge, used as an entrance hall to the saloon, steering room, and chart room. The steam-steering gear is placed at the after end of the engine casings, connected by controlling gear to the bridge steering room, and a powerful screw-gear is fitted aft. There, are four large cargo hatches, with seven powerful steam winches and a patent windlass is fitted forward for the working of the stockless anchors. The steamer is replete with every requirement for the comfortable accommodation of the crew, and for the rapid handling of cargoes. The engines and boilers have been built by the North-Eastern Marine Engineering Co., Limited, of Wallsend-on-Tyne, the sizes of the cylinders being 26 in., 44 in., 72 in., by 48 in. stroke, supplied with steam by three large boilers working at 180 lbs. pressure. The launch, which was most successful, was effected by means of hydraulic power, by Miss Dunn, of Alnwick, and was gracefully christened by Miss Handress. There was a large company present at the launch, including Miss Handress; Miss Dunn, of Alnwick; Mrs. Robert Thompson; Madame Lechère, of Antwerp; Mrs James Marr; Mr. Dunn, the managing owner; Mr. Robert Thompson, J.P., the managing director of the builders' firm; Mr. Joseph L. Thompson, J P., of Winston-on-Tees; Mr. James Marr; Messrs. Smidtz and Forceville, of the Societe John Cockerill, of Antwerp; and Mr. Thomas Bredsdorff, of the Flensburger Schiffsbau-Gesellschaft, Flensburg. After the launch the usual adjournment was made to the builders' luncheon room, where the usual toasts were duly honoured. The firm has received an order from Mr. Bredsdorff, for Mr. P. Phorson's patent hydraulic launching gear. The hull and machinery have been constructed under the superintendence of Messrs. Irwin, Atkinson & Young, of Liverpool, and under the personal supervision of Captain Kilvert. This is the second vessel built by this firm for these owners.

Riverton.—On July 24th Messrs. Ropner & Son launched from their shipbuilding yard a very fine steel screw-steamer, 325 ft. long. Her machinery will be supplied by Messrs. Blair & Co., Limited. She has been built to the order of a Newcastle firm, and, as she left the ways, received the name of *Riverton* from Miss Elizabeth Easson, daughter of the inspecting superintendent.

Sparta.—On July 24th Messrs. Richardson, Duck & Co. launched from their yard a steel screw-steamer of the following dimensions:—Length, over all, 309 ft.; breadth, extreme, 42 ft.; depth, moulded, 27 ft. 11 in.; gross tonnage, about 2,750 tons. This vessel, which has been built to the order of Messrs. A. C. de Freitas & Co., of Hamburg, will class 100 A1 at Lloyd's, and has been built under special survey. She is of the spar-deck type, with a large deck-house forward of engine casing, in which accommodation is provided for 18 first-class passengers, with smoke room, ladies' saloon, captain's room, &c., in house above. Engineers and officers are berthed in houses alongside engine-casing, and crew in topgallant forecastle. A cellular double bottom for water-ballast is fitted throughout, also after peak tank, and equipment includes large horizontal donkey boiler by Messrs. Blair & Co., four steam winches, steam windlass, stockless anchors, steam-steering gear, &c. The engines, by Messrs. Blair & Co., Limited, have cylinders 24 in., 40 in., and 65 in. by 42 in. stroke, steam being supplied by two single-ended boilers with a working pressure of 160 lbs. As the vessel left the ways she was christened *Sparta* by Mrs. H. G. Spence, of Elmwood, Hartburn, near Stockton.

LAUNCHES.—Scotch.

Kittiwake.—On June 27th there was launched from the shipbuilding yard of Messrs. T. B. Seath & Co., Rutherglen, a usual flying bridge. On top of the poop a large entrance house has been constructed. Patent stockless anchors are fitted, and a large fresh-water condenser. The vessel throughout is fitted as a first-class cattle and cargo steamer, with all the latest improvements for the rapid loading and discharging of cargoes. The machinery has been constructed by Messrs. Blair & Co., Limited, of Stockton-on-Tees, the sizes of the cylinders being 24 in., 40 in., 66 in. by 45 in. stroke, supplied with steam by two large multitubular boilers working at 160 lbs. pressure. The shafting is considerably in excess of Lloyd's requirements, and the engines have been built to a very complete specification. As the vessel left the ways the christening ceremony was gracefully performed by Miss Dora M. Jones, daughter of Captain Richard Jones, who will take command, and who is superintending the completion of the vessel which has been chiefly constructed under the superintendence of Mr. James Bailey, of Bristol. There was a large company present at the launch, which was effected by hydraulic power. The usual adjournment was made to the builders' luncheon room, where suitable toasts were duly honoured.

Lord Ormonde.—On July 8th Messrs. Dobson & Co. launched at Walker-on-Tyne a steel screw-steamer for the Irish Shipowners' Co., Limited, of which Messrs. Thomas Dixon & Sons, Belfast, are the managers. The dimensions of the vessel are:—Length, overall, 372 ft.; breadth, 46 ft. 3 in.; depth, moulded, 29 ft. 10½ in. She is built to Lloyd's highest class as a spar-deck vessel. The propelling machinery has been constructed by Messrs. John Dickinson & Sons, Limited, of Sunderland, and consists of a set of triple-expansion engines, having cylinders 24 in., 40 in., and 64 in., by 48 in. stroke. The vessel was christened *Lord Ormonde* by Miss Rosa Magill.

North Sea—On July 10th Messrs. Craig, Taylor & Co., launched from their shipbuilding yard at Thornaby-on-Tees, a steel screw steamer of the following dimensions, viz., 278 ft. by 40 ft. 8 in., by 20 ft. 6 in. moulded. She is built of steel to the highest class in Lloyd's under special survey, and is of the single-deck type, with poop, bridge, and forecastle; water ballast in double bottom fore and aft, and in peak; she is on the deep frame principle, and has large clear holds, and large hatches. She will carry about 3,000 tons deadweight on a light draught of water, and is fitted with patent steam windlass, patent steam-steering gear, four large steam winches, Meredith donkey boiler, screw-gear aft, telescopic mast to Manchester Canal requirements, and all the latest improvements. The propelling machinery has been constructed by Messrs. Thomas Richardson & Sons, Limited, Hartlepool, the cylinders being 21 in., 35 in., 57 in., by 39 in. stroke, two large boilers 160 lbs. pressure. This vessel has been built to the order of Messrs. Sanders, Wake & Co., London, under the superintendence of Mr. W. C. Carter, of 30, Great St. Helens, London. As she left the ways, she was gracefully christened the *North Sea* by Miss Wake, of London.

Petunia.—On July 10th Messrs. Cochrane & Cooper, Limited, launched from their yard at Selby a new steam trawler of the following dimensions, 115 ft. by 21 ft. 6 in. by 11 ft. 6 in., built to the order of the North-Eastern Steam Fishing Co., Grimsby. Engines of triple-expansion type are being supplied by Messrs. C. D. Holmes & Co., of Hull, and the vessel will be completed with all the most modern appliances for trawling. As the vessel left the ways she was christened the s.s. *Petunia* by Miss Alice A. Allen.

South Australia.—On July 10th this large and handsomely modelled steel screw-steamer—built for the Australian trade to the order of the Southern Steam Shipping Co., Limited, of London, of which Messrs. Lawther, Latta & Co. are the managers—was launched from the works of Messrs. Short Bros., Sunderland. This vessel, which is constructed of steel throughout, has been built under special survey to the highest class in Lloyd's register, and is of the following dimensions:—Length, 370 ft.; breadth, 48 ft.; and depth, moulded, 30 ft., with a large deadweight and carrying capacity, and has a continuous permanent shade-deck extending from forecastle to poop. Large and commodious deck-houses are fitted amidships on shade-deck for the accommodation of captain, officers, and engineers, with large and handsomely fitted saloons, the panelling being in polished hardwoods tastefully arranged. On the flying bridge deck a large and commodious teak wheel and chart house is fitted, the steam-steering gear is fitted in the engine-room with controlling rods to wheel house and flying bridge. The crew are berthed in the forecastle, which is divided by a passage-way, and further divided for petty officers, &c. The double-bottom is constructed on the cellular system, subdivided into trimming tanks, the peaks also being fitted for water ballast. The holds are four in number, which for rapid loading and discharging have been fitted with eight powerful steam winches, steam for which is supplied by a large multitubular donkey boiler placed in the stokehold. In addition, the vessel is fitted with all the newest appliances for despatch, and the economical handling of cargoes. A complete installation of electric light is also fitted. On leaving the ways the vessel was named *South Australia*, the ceremony being performed by Miss Dora T. Short, of Sea View, who was handed a very handsome present by one of the directors on behalf of the company. The vessel is to be fitted with triple-expansion engines by Messrs. Blair & Co., Limited, of Stockton-on-Tees, having cylinders 26 in., 42 in., and 70 in., with a stroke of 48 in., and two large steel boilers of 180 lbs. working pressure, fitted with Howden's system of forced draught.

Ortona.—On July 10th Messrs. Vickers, Sons and Maxim, Limited, launched at Barrow a large twin-screw steamer for the Australian mail and passenger service of the Pacific Steam Navigation Co. Miss Rankin, daughter of one of the directors of the Pacific Co., named the vessel *Ortona*. The steamer is 500 ft. long, 55 ft. beam. and 37 ft. moulded depth to upper deck, her gross tonnage being 7,600 tons. The hull is constructed of steel on the cellular double-bottom principle, and completed throughout to Board of Trade requirements. The vessel, as is the case with all the other steamers of the company, is not classed, but her scantlings are sconsiderably in excess of Lloyd's requirements. There are three complete closed-in decks, and accommodation is provided for 130 first, 162 second class, and 300 steerage passengers The machinery has been designed to give the vessel an average speed at sea when fully laden of 15½ knots. The propelling machinery consists of two sets of inverted, vertical, direct-acting, triple-expansion engines, each set having three cylinders working on separate cranks. The cylinders are:—High pressure, 30 in. diameter; intermediate pressure, 50 in. diameter: low pressure, 83 in. diameter; and the stroke 54in. The steam distribution valves are of the piston type for high pressure and intermediate pressure cylinders, and the flat double-ported description for low pressure cylinders. They are actuated by valve gear of the ordinary, double eccentric, link motion type, the reversing gear is of the "all round" type, with steam and hand-starting gear. The condensers are cast with back columns of main engines, and are supplied with circulating water from two centrifugal pumping engines. The auxiliaries in the engine-rooms consist of one large duplex ballast pump, one fire engine, two direct-acting main feed pumps, and one auxiliary feed pump, two evaporators, and one auxiliary condenser for taking exhaust steam from all auxiliary engines throughout the ship. The engines are supplied with steam from four double-ended boilers of the marine multitubular type, each fitted with eight furnaces, and worked under Howden's system of forced draught. The boilers are constructed for a working pressure of 190 lbs. per square in., to Board of Trade requirements. A large auxiliary boiler of the cylindrical type is also fitted for supplying steam to all auxiliary engines. The ashes are discharged overboard by means of silent hydraulic ejectors, one being fitted in each stokehole. The machinery throughout has been under the supervision of Mr. James Thomson, superintendent engineer of the Pacific Co., the resident inspector for hull and machinery being Mr. Hugh Brown.

Rollo.—On July 11th Messrs. Cochrane & Cooper, Limited, launched from their Grovehill Shipyard, Beverley, a new steam trawler of the following dimensions, 100 ft. by 21 ft. by 11 ft. depth of hold, built to the order of Mr. G. F. Sleight, Grimsby. Engines of triple-expansion type are being supplied by Messrs. C. D. Holmes & Co., of Hull, and the vessel will be completed with all the most modern appliances for trawling. Miss Gladys Sleight named the vessel the s.s. *Rollo*.

Ferndene.—On July 11th the Northumberland Shipbuilding Co., Limited, launched, at Howdon-on-Tyne, a large steel steamer built to the order of Messrs. J. T. Lunn & Co., Newcastle, for the Dene Line. The vessel will take the highest class under Lloyd's survey, and is 352 ft. long by 48 ft. beam, by 28½ ft. depth moulded. The steamer will carry a deadweight cargo of 6,300 tons. Messrs. Thomas Richardson & Sons, Limited, of Hartlepool, will supply the machinery, which consists of a set of triple-expansion engines, having cylinders of 24 in., 40 in., and 66 in. diameter, with a stroke of 45 in., supplied with steam by two large single-ended boilers, working at a pressure of 180 lbs. The steamer was named *Ferndene* by Miss Edith Lunn, daughter of the managing director of the Dene Line.

British Princess.—On July 11th the Palmer's Shipbuilding and Iron Co., Limited, launched from their Jarrow yard a finely modelled steel twin-screw-steamer of the following dimensions:—Length (between perpendiculars), 470 ft; breadth extreme, 56 ft. 6 in.; depth moulded, 35 ft., constructed for the British Shipowners' Co., Liverpool. The vessel will be rigged as a four-masted fore-and-aft schooner, and has been built under special survey to take the highest class in Lloyd's registry. She is of the three-decked type, with two steel decks laid all fore and aft, and has a closed-in shelter deck specially strengthened for the Atlantic trade, extending over the whole length, and above this a shade deck covering the machinery openings. All the available space under the shelter and shade decks is left clear for carrying horses. The vessel is designed to carry upwards of 10,000 tons deadweight on about 27 ft. mean draught. The engines, which are also being constructed by the Palmer Co. are of the triple-expansion twin screw type, with cylinders 26 in., 43 in. and 71 in. diameter by 48 in. stroke, steam being supplied by two double-ended boilers and two single-ended boilers with a working pressure of 190 lbs. On leaving the ways she was named *British Princess* by Mrs. Beazley, wife of Mr. Edwin Beazley, one of the managers of the British Shipowners' Co.

Drumbain.—On Tuesday, July 11th, Messrs. W. Gray & Co., Limited, launched a fine large steel screw-steamer, which they have built to the order of Messrs. W. Christie & Co., of London. She will take Lloyd's highest class, and is of the following dimensions, viz.:—Length over all, 336 ft.; breadth, 48 ft. 6 in.; and depth, 24 ft. The deck erections consist of poop, long bridge, and forecastle. The saloon and captain's and officers' rooms will be fitted in the poop. The hull is built with deep frames and cellular double bottom and aft peak tank for water ballast, five steam winches, steam-steering gear amidships, hand screw-gear aft, patent direct steam windlass, patent donkey boiler, grain divisions, stockless anchors; and a complete outfit will be fitted for a first-class cargo boat. Three cylinder triple-expansion engines of first-class make are being supplied by the Central Marine Engine Works of Messrs. W. Gray & Co., Limited. They will develop over 1,200 H.P. The cylinders are 24 in., 38 in., and 64 in. diameter, with a piston stroke of 42 in., and large steel boilers to work at a pressure of 160 lbs. per square inch. The ceremony of christening the steamer *Drumbain* was gracefully performed by Miss Florrie Mudd, of Hartlepool.

Hydra.—On July 19th Messrs. Wood, Skinner & Co., Limited, successfully launched from their shipbuilding yard, at Bill Quay, Newcastle-on-Tyne, a handsome new steel screw-steamer, which has been built to the order of Messrs. Bruusgaard, Kiosterud & Co., of Drammen, Norway. The vessel is a sister ship of the s.s. *Hugin*, recently built by that company for the same owners. She is of the improved single-deck type, with bridge and topgallant forecastle, and her principal dimensions are as follow, viz.: Length, 248 ft.; breadth, 35 ft.; depth, moulded, 20 ft. 6 in. The vessel will be fitted with a set of engines of the improved triple-expansion type, having cylinders 18½ in., 30 in., and 49 in. diameter respectively, with a stroke of 33 in., supplied with steam from a large steel multitubular boiler working at 160 lbs. pressure per square inch. The engines and boiler have been constructed and will be fitted by the North Eastern Marine Engineering Co., Limited, at the Northumberland Engine Works, Wallsend-on-Tyne. Both the vessel and engines have been built to the highest class, viz., 1 A1* Norwegian Veritas, and have been surveyed during construction by Mr. Lauritz M. Bodin, of Sunderland, the local representative, and also superintended by Mr. Norman Burnett, of Newcastle-on-Tyne, on behalf of the owners. She will be rigged as a fore-and-aft schooner, and fitted with telescopic topmasts, as also with all the latest improvements and appliances in the way of deck machinery, for facilitating the rapid loading and discharging of cargo and general working and navigating. As the vessel left the ways she was christened *Hydra* by Mrs. Gabrielle, wife of Captain Gabrielle, of Christiania, Norway, who will command the steamer when completed and ready for sea. The *Hydra* is the fifth vessel constructed by the builders for Messrs. Bruusgaard, Kiosterud & Co.

Newton Hall.—On July 20th this finely modelled steel screw-steamer was launched by Messrs. Joseph L. Thompson & Sons, Limited, of the North Sands Shipbuilding Yard, Sunderland. She has been built to the order of Messrs. C. G. Dunn & Co., of Liverpool. The principal dimensions of the vessel are:—Length over-all, 379 ft. 6 in.; breadth, extreme, 49 ft. 6 in.; and depth, moulded, 29 ft. 6½ in. The vessel is built on the spar-deck rules to Lloyd's 100 A1 class, under their special survey, and is a fine example of the modern cargo vessel, with all the latest improvements and requirements for the owners' special trade. Water ballast is carried in a cellular double bottom, right fore and aft, and also in the after peak. The accommodation for the saloon, captain, officers, and also spare berths for the accommodation of a limited number of passengers, is placed at the fore end of the bridge, and for the engineers in sidehouses at the after end of the bridge. The crew, firemen, apprentices, and petty officers are berthed in the topgallant forecastle. The vessel is rigged as a two-masted fore-and-aft schooner, with telescopic topmasts to suit the Manchester Ship Canal. A large house is placed at the fore end of the bridge, used as an entrance hall to the saloon, steering room, and chart room. The steam-steering gear is placed at the after end of the engine casings, connected by controlling gear to the bridge steering room, and a powerful screw-gear is fitted aft. There, are four large cargo hatches, with seven powerful steam winches and a patent windlass is fitted forward for the working of the stockless anchors. The steamer is replete with every requirement for the comfortable accommodation of the crew, and for the rapid handling of cargoes. The engines and boilers have been built by the North-Eastern Marine Engineering Co., Limited, of Wallsend-on-Tyne, the sizes of the cylinders being 26 in., 44 in., 72 in., by 48 in. stroke, supplied with steam by three large boilers working at 180 lbs. pressure. The launch, which was most successful, was effected by means of hydraulic power, by Miss Dunn, of Alnwick, and was gracefully christened by Miss Handress. There was a large company present at the launch, including Miss Handress; Miss Dunn, of Alnwick; Mrs. Robert Thompson; Madame Lechère, of Antwerp; Mrs James Marr; Mr. Dunn, the managing owner; Mr. Robert Thompson, J.P., the managing director of the builders' firm; Mr. Joseph L. Thompson, J P., of Winston-on-Tees; Mr. James Marr; Messrs. Smidtz and Forceville, of the Societe John Cockerill, of Antwerp; and Mr. Thomas Bredsdorff, of the Flensburger Schiffsbau-Gesellschaft, Flensburg. After the launch the usual adjournment was made to the builders' luncheon room, where the usual toasts were duly honoured. The firm has received an order from Mr. Bredsdorff, for Mr. P. Phorson's patent hydraulic launching gear. The hull and machinery have been constructed under the superintendence of Messrs. Irwin, Atkinson & Young, of Liverpool, and under the personal supervision of Captain Kilvert. This is the second vessel built by this firm for these owners.

Riverton.—On July 24th Messrs. Ropner & Son launched from their shipbuilding yard a very fine steel screw-steamer, 325 ft. long. Her machinery will be supplied by Messrs. Blair & Co., Limited. She has been built to the order of a Newcastle firm, and, as she left the ways, received the name of *Riverton* from Miss Elizabeth Easson, daughter of the inspecting superintendent.

Sparta.—On July 24th Messrs. Richardson, Duck & Co. launched from their yard a steel screw-steamer of the following dimensions:—Length, over all, 309 ft.; breadth, extreme, 42 ft.; depth, moulded, 27 ft. 11 in.; gross tonnage, about 2,750 tons. This vessel, which has been built to the order of Messrs. A. C. de Freitas & Co., of Hamburg, will class 100 A1 at Lloyd's, and has been built under special survey. She is of the spar-deck type, with a large deck-house forward of engine casing, in which accommodation is provided for 18 first-class passengers, with smoke-room, ladies' saloon, captain's room, &c., in house above. Engineers and officers are berthed in houses alongside engine-casing, and crew in topgallant forecastle. A cellular double bottom for water-ballast is fitted throughout, also after peak tank, and equipment includes large horizontal donkey boiler by Messrs. Blair & Co., four steam winches, steam windlass, stockless anchors, steam-steering gear, &c. The engines, by Messrs. Blair & Co., Limited, have cylinders 24 in., 40 in., and 65 in. by 42 in. stroke, steam being supplied by two single-ended boilers with a working pressure of 160 lbs. As the vessel left the ways she was christened *Sparta* by Mrs. H. G. Spence, of Elmwood, Hartburn, near Stockton.

LAUNCHES.—Scotch.

Kittiwake.—On June 27th there was launched from the shipbuilding yard of Messrs. T. B. Seath & Co., Rutherglen, a she made a most satisfactory run of 10½ knots on the measured mile. The vessel was constructed under the supervision of Messrs. Flannery, Baggallay & Johnson, of London and Liverpool.

Winifredian.—Lately the new steamer *Winifredian*, belonging to the Leyland Line, intended to trade between Liverpool and Boston, U.S., and built by Messrs. Harland & Wolff, of Belfast, reached Liverpool after making her trial trip. This steamer is fitted in Harland & Wolff's well-known style for 135 first-class passengers, with all the accommodation on the saloon or upper deck, and with all the appointments for the passengers of a first-class liner. Her dimensions are:—552 ft. length overall, with a beam of 159 ft., and a displacement of no less than 20,030 tons. The engine-power is 5,500 H.P., and her total deadweight capacity is about 13,000 tons. It is estimated she could steam round the world without recoaling, and besides carrying about 1,000 horses and 1,000 troops, would still have sufficient carrying capacity left to carry 3,000 or 4,000 tons of stores.

India.—On July 3rd the fine steel screw-steamer *India*, built by Messrs. Sir Raylton Dixon & Co., Limited, Cleveland Dockyards, Middlesbrough, for the Austrian Lloyd's Steam Navigation Co., of Trieste (of which we gave full particulars in our Launch columns, June issue, page 134), proceeded out to sea for her official trials, under the command of Captain Martinolich. The hull and machinery have been built under the supervision of Mr. Vico Vecchi, naval architect to the owners. Mr. Konhauser, director of the Austrian Lloyd Steam Navigation Co., Mr. Nardin, superintendent engineer, &c., &c., were present at the trial trip, which passed off most successfully.

Auchenarden.—On July 3rd the new steel screw cargo s.s. *Auchenarden*, built by Messrs. Russell & Co., Port Glasgow, and engined by Messrs. Rankin & Blackmore, Greenock (of which we gave particulars in our Launch columns, July issue, page 174), went down the Firth of Clyde on her trial trip with a representative company on board. After running the measured mile the vessel steamed out beyond Cumbrae Head, and returned at full speed to the Tail of the Bank. The engines worked satisfactorily in every way, and a mean speed of 11½ knots was attained on the trial. This fine steamer is fitted with all the latest improvements for the rapid discharge and loading of cargoes, and much satisfaction was expressed with the steadiness of the vessel and the smoothness with which the engines ran.

Cassandra.—On July 4th the new steam yacht *Cassandra*, 228 tons, designed and built by Messrs. Day, Summers & Co., of Northam Iron Works, Southampton, for Mr. F. M. Huth, of Eaglehurst, went out for a trial trip run, and the results obtained were exceedingly satisfactory, the guaranteed speed being considerably exceeded. The dimensions of the yacht are:—Length, 130 ft.; beam, 19 ft.; depth, 12 ft. 6 in. The engines are of the triple-expansion type, the cylinders being 11 in., 17½ in., and 28 in. diameter, and the stroke 21 in. The boiler is 10 ft. diameter and 9 ft. long, working pressure 160 lbs. The speed obtained at the measured mile in Stokes Bay was 11¾ knots, everything working most smoothly with an entire absence of vibration. A series of progressive runs were also made at the mile, by which it was ascertained that a sea-going speed of 10½ knots could be maintained with very economical results.

Brier.—On July 5th the s.s. *Brier*—Laird Liner—which has received new boilers and undergone a thorough overhaul, so as to fit her for the general Irish trade, had a cruise in the Firth of Clyde. A special train conveyed to Gourock the partners—Messrs. G. S. MacLellan, Lewis MacLellan, Wm. MacConnell, J. F. MacLellan, R. G. Turnbull, and J. Imrie—their personal friends, representatives of railway and steamboat companies, and the company's employees, whose annual trip was conjoined with the opening cruise of the vessel. Delightful weather prevailed, and the outing was most enjoyable. The steamer, which was under the command of Captain M'Larty, ran down to Pirnmill, turned, and then hugged the Arran shore round to Brodrick Bay. As a result of the new boilers the speed of the vessel had been increased by a half knot per hour. The *Brier* will take up the Glasgow and Londonderry trade after the Fair holidays, with occasional relief work on the Sligo and Dublin route.

Sirdar.—On July 7th the steel screw-steamer *Sirdar*, built by the Grangemouth Dockyard Co., to the order of Messrs. Orders & Handford, of Newport, for the Orders & Handford Steamship Co. (Limited), (of which we gave particulars in our Launch columns, July issue, page 174), went down the Firth of Forth on her official trip. Both the owner, Mr. Handford, and Mr. Boddy, consulting and superintending engineer, of Newport, who superintended the construction of the vessel and machinery, expressed themselves as entirely satisfied.

Waverley.—On July 8th the latest addition to the Clyde fleet of the North British Steam Packet Co.—the *Waverley*, launched on May 29th, from the yard of Messrs. A. & J. Inglis, Pointhouse—completed her official trials. The vessel is of much larger dimensions than any of the other boats of the company's fleet. She will take the place of the *Redgauntlet* on the daily excursion from Craigendoran round the island of Bute, besides taking part in the general service of the system. The vessel is licensed to carry about 1,500 passengers, a fact which indicates that she ranks among the largest of the pleasure steamers on the Clyde. Not only so, but she has been designed and engined to secure great swiftness, and the results of the trials more than met the stipulated requirements, the vessel having made on the measured mile a speed equal to 19·73 knots an hour. This is said to surpass the speed of any similar boat on the river.

Inchkeith.—On July 8th was witnessed the official trial of the above-named steamer, which is noteworthy as being that of the second steamer in which has been fitted a set of Mudd's patent five-crank quadruple-expansion machinery by the Central Marine Engine Works of Messsrs. W. Gray & Co., Limited, for Messrs. Hamilton, Fraser & Co., of Liverpool. This new departure in marine engine building was taken by the late Mr. Mudd, the first set, as will be remembered, being fitted in the s.s. *Inchmona*. The object in the design of these engines and boilers is the attainment of further economy in coal consumption; and the results obtained in the *Inchmona* have fully justified the anticipations of the builders. But advances of so important a nature could not be made without the confidence and co-operation of those whom they are mainly intended to benefit, and in Messrs. Hamilton, Fraser & Co. the builders found a firm far-seeing and enterprising enough to cordially co-operate with them in their endeavours. As a result of this enterprise they may justly claim, as the owners of the *Inchmona*, to be the possessors of the most economical steamer afloat, the consumption of coal per I.H.P. per hour in that steamer not having averaged more than 1·15 lbs. over the whole period during which she has been at sea, viz., since May, 1896. This reduced coal consumption gives larger available capacity for cargo carrying, which means both increase of earnings and decrease of outgoings. The *Inchkeith* is a handsome steel screw-steamer taking Lloyd's highest class, and is 348 ft. in length, 47 ft. in breadth, and 28 ft. 1½ in. in depth; her deadweight capacity being 5,600 tons on 22 ft. 5 in. draught, which is somewhat more than that of the *Inchmona*. She is of the improved spar-deck type, with large measurement capacity, having poop, long bridge, and topgallant forecastle, with all the cabin, officers', and engineers' accommodation on the bridge. She is fitted with double bottom forward and a deep cargo tank aft, and has a total water ballast capacity of 1,287 tons. The engines are of the same size as those fitted in the *Inchmona*, viz., 17 in., 24 in., 34 in., and two of 42 in. diameter, with a piston stroke of 42 in. The boilers are of the ordinary cylindrical multitubular type, built for a working pressure of 260 lbs, per square inch, and adapted to work with Ellis & Eaves' type of induced draught. In addition to the main feed pumps on the engines, a pair of Weir's pumps are fitted. Feed water filters on Mr. Edmiston's patent are fitted, a Mudd's evaporator, and other specialities. The trial was in every way satisfactory, a speed of over 11½ knots being averaged. After disembarking her visitors, the *Inchkeith* proceeded on her voyage to Barry, where she loads for Naples. It may be interesting to note that Messrs Hamilton, Fraser & Co. are so satisfied with the results obtained from this system that they have now placed an order for another boat, to be fitted with five-crank engines, with Messrs. W. Gray & Co.

Enidwen.—On July 13th the new screw-steamer *Enidwen*, built and engined by Messrs. John Readhead & Sons, West Docks, South Shields, to the order of Messrs. Jones, Cardiff (of which we gave particulars in our launch columns, July issue, page 171) was taken to sea on her official trial trip. A mean speed of 11½ knots was obtained, the trial proving in every way satisfactory. After the trial the vessel returned to Tyne Dock to take in bunkers. She will be commanded by Captain Richards.

Granit.—On July 13th the s.s. *Granit* proceeded on her trial trip in the Firth of Clyde. The *Granit* is a fine single screw-steamer of the well-deck type, having long poop and forecastle. She has been built for cargo carrying purposes by the well-known firm of Messrs. S. McKnight & Co., Limited, Ayr, for Norwegian owners. The dimensions of the vessel are 180 ft. by 30 ft. by 12 ft. 6 in., and she is capable of carrying about 730 tons deadweight on her register tonnage of 240, while at the same time she has a cubic capacity of about 36,000 cubic feet. The *Granit* has been constructed to the highest class of Norwegian Veritas under special survey, having cellular double bottom specially strongly constructed for loading aground and provision for sailing among ice. She has steam-steering gear amidships, steam windlass, powerful steam warping capstan aft and modern powerful steam winches for the quick handling of cargo. After the preliminary run the vessel was put on the measured mile at Skelmorlie. Six runs were taken, and a speed of 10·72 knots was attained, the vessel at the time being fully loaded and in sea-going trim. The machinery has been supplied by Messrs McKie & Baxter, engineers, of Govan, and has also been constructed under Norwegian Veritas rules for the highest class. It consists of a set of triple-expansion engines, 15 in., 25 in., and 40 in. by 27 in. stroke, and a large horizontal return tube boiler working at 160 lbs., also a large donkey boiler for working auxiliary machinery. Special donkey pumps are fitted, as also a large pulsometer for dealing with water ballast. The machinery department is fully up to modern requirements, and is provided with a Harrison's evaporator and feed heater, also a Harris' patent filter, and is in many respects a duplicate of machinery previously supplied for another steamer. During the trials the machinery worked satisfactorily, and the results attained were all that could be desired, being in fact considerably in excess of the guarantees. After completion of the trials the vessel proceeded on her maiden voyage to Plymouth, en route for Norway.

Undine.—On July 14th the steam trawler *Undine*, built by Messrs. M'Kie and Thomson, Govan, for the South African Fisheries Co., Cape Town, had her official trial trip, when a mean speed of 10 knots was made on the measured mile. The triple-expansion engines by Messrs. Lidgerwood, Coatbridge, worked very satisfactorily at 120 revolutions, and indicating 448 H.P. The plant and insulation has been built throughout to the satisfaction of Lloyd's and owners' consulting engineer. The machinery is designed to run long periods with little attention, and is capable of reducing the holds, which have 2,106 cubic ft. of space, to 26 deg. Fahr. in about 12 hours. The captain has a special cold chamber fitted in his mess room aft for preserving the meat in the warm climate. The vessel has been equipped with the latest modern otter trawl gear, and is the best equipped vessel of her kind which has left the Clyde.

Forth.—On July 15th the trial trip of the steam trawler *Forth* took place, and proved satisfactory, a speed of about 10 knots being attained. The vessel was recently launched for Hull owners by the Irvine Shipbuilding and Engineering Co. (Limited), Irvine, and is equipped with all the latest appliances for the North Sea fishing. Her dimensions are: —105 ft. by 21 ft. by 11 ft. moulded, and the engines, which were supplied by Messrs. Muir & Houston, Limited, Glasgow, are triple-expansion, having cylinders 10 in., 16 in. and 27 in., by 20 in. stroke.

Golden Eagle.—On July 15th the steam yacht *Golden Eagle*, 445 tons, the property of Sir Samuel Scott, Bart., designed by Messrs. G. L. Watson & Co., and built by Messrs. Ramage & Ferguson, Limited, Leith, went on her trials in the Firth of Forth, when a mean speed of 13½ knots was obtained on a run from Inchkeith to the May Island. The engines worked throughout with great smoothness, and with an entire absence of vibration. She will leave Leith early in August for the West Highlands.

Elba.—On July 17th the s.s. *Elba*, 1,080 tons, recently launched by Messrs. Ramage & Ferguson, Limited, Leith, for Messrs. James Currie & Co., also of Leith, went on her trial trip on the Firth of Forth. The engines worked perfectly, and a speed of 10 knots was obtained on the measured mile. The trial was in every way satisfactory.

Luciline.—On July 20th Messrs. Sir W. G. Armstrong Whitworth & Co. took this vessel on her trial trip. The vessel is the second tank steamer being constructed by that firm to the order of Messrs. Lane & Macandrew, of London (of which we gave full particulars in our Launch columns, July issue, page 170). She has been constructed under the immediate supervision of Messrs. Flannery, Baggallay & Johnson, of London and Liverpool. The vessel was taken for four runs, and attained the successful speed of 11 knots.

Miscellaneous.

Institution of Naval Architects.—At the summer dinner of this Institution, held at Newcastle on Tuesday evening, July 18th, M. Emile Bertin conveyed an invitation to the Institution to take part in an International Congress on Naval Architecture, to be held next year in Paris. He said: "My lords and gentlemen, if the pleasure which we experience in coming to hospitable England to take part in your professional and social gatherings can be accompanied with a regret, it is that of being able too seldom to invite you, on our side, to these congresses which are of such great advantage to the science of all countries. We eagerly seize then on this occasion the opportunity which the holding of the International Exhibition of 1900 presents. The Committee of the International Congresses to be held during the exhibition is of the opinion that there is nothing of such an essentially international character as naval architecture, whose business is to establish communication between all shores. We propose, consequently, to hold such a Congress, commencing on July 19th, next year. It would not be accurate to say that we merely invite you to this Congress. Much more, we ask for your assistance—the assistance of the first Institution which founded in this country a centre of scientific investigation and study for naval construction. I am charged by the French Minister of Marine to convey to you the expression of his wishes. I need hardly say that I add to these the hopes of your French colleagues, who are happy to be able to give you a rendezvous next year at Paris. We will unite our hopes that the 20th century may be a brilliant one for naval architecture in general, and for the British Institution of Naval Architects in particular."

Steam and Hydraulic Packing.—It is surprising the amount of enterprise shown by manufacturers in these days in reference to the various details connected with engineering, and in no class of goods is this more prominent than that of packing for glands and similar devices. Messrs. R. & J. Rankin, Union Foundry, 22, Manchester Street, Liverpool, have been conducting a long series of experiments, with the view of producing a packing for general use which should be, as far as possible, free from the objections to many of the packings now being used, especially in view of the increasing steam pressures now so common. It is a fault with many packings that if the outer covering gives way, the whole is rendered useless; whilst in other packings, if one strand has worn through, the other strands with which it is plaited are released, and the packing becomes uneven, and thus constitutes a hindrance instead of an aid to the running of the machinery. The makers for obvious reasons do not care to say much as to the composition of this packing, but we understand it is a mixture of asbestos with other important ingredients, including a lasting lubricant and another substance, upon which its success largely depends. We have seen testimonials from important steamship companies who have adopted it after satisfactory trials.

Robert Stephenson & Co., Limited.—The business of this firm has been sold to a new company, whose directors will be:—Sir Joseph Whitwell Pease, Bart., M.P. (chairman, Pease & Partners, Limited), Chairman; Sir Raylton Dixon (chairman, Sir Raylton Dixon & Co., Limited); Sir Christopher Furness (chairman, Furness, Withy & Co., Limited); Joseph Albert Pease, Esq., M.P. (director, Pease & Partners, Limited); Lieut.-Col. Philip Watts (director, Sir W. G. Armstrong, Whitworth & Co., Limited). Henry Withy, Esq. (managing director, Furness, Withy & Co., Limited). The business will be carried on as usual until the new company takes possession.

A Smart Piece of Engineering Work in Middlesbrough.—It will be remembered that an accident occurred recently at the Stockton Malleable Iron Works when a large flywheel gave way, resulting in the stoppage of an important part of the works. It was necessary that a new wheel be made as quickly as possible, and this work has been carried out very expediously by Messrs. Sir Christopher Furness, Westgarth & Co., Limited, of Middlesbrough. The wheel which is 17 ft. 4 in. diameter and weighs 313 tons was completed in 11 working days from receipt of order, and considering that the wheel is a built one with a large amount of work in it, this appears to be an exceptionally smart piece of engineering work.

Messrs. Wood & Newland (late assistants to Messrs. Wheatley, Price & Goulty), have opened offices at 42, Spring Gardens, Manchester, and are prepared to undertake valuations, whether intended for flotation, transfer, adjustment of capital account, debenture or loan securities, probate, or other purposes; to make periodical examination of works and report thereon; also to negotiate partnerships, and sale of works either by private treaty or by public auction.

The Institution of Junior Engineers.—The Institution of Junior Engineers, of which the president is Sir W. H. White, K.C.B., Director of Naval Construction and Assistant Controller of the Navy, holds its summer meeting this year at Portsmouth and Southampton, commencing August 12th. The Government establishments, engineering works, &c., in the neighbourhood are to be visited, and whilst at Southampton, in addition to the L. and S. W. Railway Co.'s docks, an inspection will be made of the North-German Liner *Kaiser Wilhelm der Grosse*, and the American Liner *St. Louis*. The mayors of both towns are offering entertainment to the institution.

The Marine Engineer.

LONDON, SEPTEMBER 1, 1899.

THE Americans are pushing along their increase of Navy and carrying out the work in their own yards with all the latest improvements in labour-saving tools. We have no doubt they could give our shipyards wrinkles in labour-saving devices, as American workmen have no prejudices about producing any amount of work per man, provided appliances are given them which will enable them to do such maximum work with ease to themselves. We wish our workmen would look at the matter in the same light, but, unfortunately, it is well within the experience of every employer of engineering labour that when special tools and jigs have been provided to enable men to double or treble their output with an advantage to themselves on piecework of even 50 per cent. an increase of wages, they are prevented by their fellow-workmen from availing themselves of the opportunity so beneficial to themselves and their employers, owing to the fear of taking work out of the hands of others. Three battleships are now being built at Newport News, two of which are in the water and nearly completed. Many of the weighty parts, such as the gun turrets, were built and received their armour on shore, and were placed in position by a 150-ton crane. This crane, which is, we believe, the largest in the world, is worked by electricity and is as easy to handle as a motor car. The Newport News Yard has a frontage of half a mile on the James River, and is fitted throughout with hydraulic mains, which may be measured in miles. The hydraulic power is used not only on the ships, both in the slips and in the dry docks, for riveting, hauling, and other usual purposes, but also largely for hand tools—such as for chipping, drilling, &c. Pneumatic hand tools are also used for caulking, and whenever motive power can be substituted for manual labour in any of the usual engineering operations, it is done, and is kindly adopted by the workmen. It is only by the means of such special tools and labour-saving appliances that the high-waged American artisan can produce, as he does, such excellent work at a price not much above the cost of other nations with labour at half the price, and in many cases can even compete with them.

THE Hon. A. C. Parsons is proposing to revolutionise the Navy, as regards at any rate the speed of transit. He considers that 48 knots an hour is within the reach of practical politics where the turbine engine is employed. There can be no doubt that with a practicable rotary engine, such as the Parsons turbine engine, there is practically no limit to the H.P. that such engines can be made to develop in comparatively small space and with little weight of material, compared with reciprocating engines, provided a sufficiency of boiler power can be crammed into the hull. The water-tube boiler has now made this practicable within certain limits of space and weight for boilers and contained water, far beyond what was possible with the old system of boilers. When therefore Mr. Parsons speaks of a light cruiser of 3,000 tons displacement containing 120,000 maximum effective H.P. in the form of water-tube boilers and turbine engines, he speaks of what is at least possible and probably sufficiently practicable for immediate experiment. The coal supply, however, for such power to any radius of action must be immense, as the coal consumption increases as the cube of the speed, and consequently the coal supply per radius of movement will be much increased as compared with present normal or maximum speeds. No doubt the reply to this would be that the greater portion of any required cruise could be traversed with few boilers in use and at a normal or comparatively economical speed, and that the reserve power of such an enormous speed as 48 knots would only be used for a short time for emergencies of defence or offence. Certainly no locomotive torpedo could catch a ship with such a speed, nor could any heavily armed cruisers or battleships approach her unless she were taken unawares. From a commercial point of view, we are of opinion that economical highest rates of speed have already been reached, unless it were for special light mail steamers with small accommodation for passengers who would not mind paying a double or treble rate of passage for highest speed of transit.

THE summer meeting of the Institution of Mechanical Engineers at Devonport was signalised by a paper read by Mr. R. H. Champness, the chief constructor of H.M. Dockyard, Devonport, upon the launch of a battleship. The launch of the *Ocean* was the first case of the launch of a modern battleship from the Devonport slips, it having previously been thought that battleships could not be built at Devonport, the nearest approach to this having been a steel cruiser whose launching displacement was only 2,830 tons, in 1890. The launching weight of the *Ocean* was 7,110 tons, which was a great excess of weight for the old slips, but they have stood the excess pressure so well that during the last twelve months three such ships have been upon the blocks, of which two are now afloat, the third is well advanced for launching, and a fourth is soon to be laid down. Devonport Dockyard has thus fairly established a permanent reputation of being able to build and launch first-class battleships. The weight of the *Ocean* is not a record weight for ships launched from Imperial Dockyards and has been far eclipsed by the Belfast *Oceanic*, whose launching weight was 11,000 tons. Mr. Champness took the opportunity afforded by the record of this launch to bring together into his paper a detailed account of the principles and the work involved in the launch of a large battleship, with calculations of moments, pressures, and buoyancy curves as the vessel is gradually water-borne, which will be valuable as a reference to any reader, and of great benefit to the students in training at the Royal Naval Engineering College at Devonport, for whose benefit indirectly the paper was prepared. The author deals first with building slips, and the declivity of building, and then proceeds to indicate means forcal culation of launching weight, and the movement of the centre of gravity over the slip. Then all details of the groundways cradle are fully detailed and maximum stresses pointed out. The necessity for internal shoring between deck is shown, together with their approved disposition in this vessel. The lubrication of the sliding ways is fully dealt with, including the mode of and material for the lubrication of the various parts. Then come the final preparations of setting the ship, the estimation of the elasticity of the hull in bogging or sogging, and finally the freeing of the dog shores, and the actual launching, with precautions as to leakage when first afloat, and the checking of the velocity of the launched vessel. We have rarely, if ever, seen so interesting a detailed account of the various arrangements and precautions in handling and launching successfully so weighty a mass.

We are sorry to hear that the local Harbour Commissioners of Belfast are standing in the way of their country's good, and the industrial advancement of Belfast by placing obstacles in the way of the legitimate expansion of the magnificent shipbuilding yard of Messrs. Harland & Wolff. We understand that an application by this firm for 40 acres of reclaimed land adjoining their shipbuilding yards, for extension purposes, has been refused. As a result it is said, that the number of employees which would have been engaged by the firm will be reduced by 2,000. Surely when so much is said and done by England to encourage local industry in Ireland, where there is the faintest hope of commercial success, it is a *reductio ad absurdum* that such an opportunity of extension of a well-established and successful business should be checked by the local authorities themselves. *Perhaps* under such repressive treatment Messrs. Harland & Wolff will find it advantageous to cross to the other side of St. George's Channel, where they would be welcomed.

PROBABLY the greatest grievance which the men engaged in shipbuilding in the North of England and Scotland have had to endure, has been lack of employment at various times for long intervals, owing to the depressed condition of their trade. A great proportion of these persons would not have felt this grievance very sorely if they had been anything like sufficiently provident during the busy periods of their industry. Now, for many months during the prosperous period of the shipbuilding industry, the owners of the shipbuilding-yards on the Clyde and the Tyne have been, and are, so busy that they cannot complete their orders within the agreed time in many cases, whilst in other instances they have had great difficulty in doing so, in consequence of the majority of their workmen refusing to labour continuously for six days each week. Notwithstanding the higher wages paid to them, the result has been that very many orders for shipbuilding materials for ships and repairing them have been given to foreigners which would otherwise have been placed with our own countrymen. It has been well stated by a contemporary that the employees are short-sightedly acting against their own larger interests, and are giving to the alien half the loaf when, with energy, they might keep the whole to themselves. British and Irish engineering and other companies who derive much of their income from shipbuilding and ship-repairing are now very reluctant to lay down fresh plant and new machinery to accelerate the completion of the recent rush of orders they have received, as this rush is owing more to the accumulation of arrears in consequence of the recent prolonged engineers' strike than otherwise; and, therefore, after the present busy period has passed, such extra plant and machinery would not be used, or only to a small extent compared with what it now is. This being so, it is well to bear in mind that when foreigners have won a success in a manufacturing business in competition with those engaged in a similar industry at home by the more rapid production by the former of plant and machinery of equal or better quality, and at the same or lower prices, than those of their rivals in the United Kingdom, the foreigners have, as a rule, generally increased their orders at a great ratio annually from the people of this country to the injury of their home competitors and other persons whose pecuniary interests are more or less affected by them. Owing to this result, when slack times arrive in the British and Irish shipbuilding industry, not only will those workmen engaged therein probably have less wage-earning work to do than they previously had as a class during temporary depressions in shipbuilding, in consequence of extra keenness of competition between British and foreign shipbuilders and ship-supplies manufacturers, but this grievance will probably be much, and almost intolerably, aggravated by the new and increasing practice adopted by many large engineering and other manufacturing companies of ceasing to employ even competent workmen who are 50 years of age and upwards. The reason of this new step being taken is to minimise, as far as possible, the risk to which employers are exposed to pay compensation to their workmen for injuries suffered by them in the ordinary course of their employment under the Workmen's Compensation Act of 1897. For these reasons, and the fact that want of employment in and incident to shipbuilding in the North of England and Scotland has resulted in awful distress amongst those workmen and their families who have been seriously subjected to this evil, we feel bound to emphatically state that the recent improvident, reckless practice of shipbuilding employees in these parts of Great Britain of wasting their time and money by not working full time weekly is much to be condemned, and systematic and well-directed efforts should, without delay, be adopted to materially diminish, if not to get rid of, this grievance.

THE MACHINERY OF H.M.SS. "PROSERPINE" AND "PSYCHE."

AS ILLUSTRATIVE OF THE WORK DONE AT KEYHAM, PARTICULARLY WITH REFERENCE TO THE PRACTICAL TRAINING OF ENGINEER STUDENTS.*

By Mr. ROBERT MAYSTON, R.N.,
Chief Engineer, H.M. Dockyard, Devonport..

For some years, in addition to the general work of repairs to the machinery of ships, there has been continnously new machinery in course of manufacture. The ships for which the machinery has been manufactured at this dockyard comprise the following:—

Pheasant	each of 1,200 I.H.P.
Partridge	
Lapwing	
Ringdove	
Phœbe	7,500 I.H.P.
Astræa	9,000 ,,
Talbot	9,600 ,,
Phœnix	each 1,400 I.H.P.
Algerine	
Proserpine	each 7,000 I.H.P.
Psyche	

and at the present time the engines and boilers for H.M.'s sloops *Rosario* and *Vestal*, each of 1,400 I.H.P., are in progress.

The designs are worked out in the chief engineer's drawing office, receive Admiralty criticism and final approval before the work of manufacture is put in hand, and, with the exception principally of the steel castings and larger steel forgings, such as shafts, the various parts of the machinery are made and fitted at the yard. It is thus seen that each entry of engineer students of recent years has, during its course of training, had the opportunity of witnessing the construction of, and taking part in, the manufacture, erection in the shop and on board the ship of at least one set of machinery for a warship, involving the most up-to-date practice of the time.

Of the two latest completed ships above tabulated, the *Proserpine* and *Psyche*, the engines and boilers of both were manufactured at Keyham, but in the case of the first named were fitted on board at Sheerness, whereas in the *Psyche* the whole of the work, both manufacture and fitting on board, was carried out at Keyham. Both are third-class cruisers of a type of which there are several in Her Majesty's navy, either completed or under construction. The machinery comprises in each case two independent sets of triple-expansion engines, each with three vertical cylinders of diameters 20½, 33, and 54 in., the length of stroke being 2 ft. 3 ins, and were designed to obtain with each set 3,500 I.H.P., or 7,000 I.H.P. with both sets, the boilers being worked under air pressure, and the steam pressure available at the engines being 250 lbs. per square inch.

Arrangement of Engines.—The general arrangement of the engines is shown on the illustrations which accompany this paper. Figs. 1 and 2 give views of the engines taken from forward, and Fig. 3 gives a view taken from aft. Figs. 4 and 5 give elevation and plan of the engines, showing sections through the cylinders and disposition of the columns, bearings, &c., and Fig. 6 shows the elevation and plan of the arrangement of the machinery throughout the ship, giving positions of auxiliary engines, &c.

The cylinders are independent castings, the high-pressure and intermediate-pressure unjacketed, and the low-pressure jacketed; the working barrels of the latter are made separately, and the pressure of steam arranged for in the jackets 45 lbs. per square inch.

The slide valves of the high-pressure and intermediate-pressure cylinders are of the piston type; those of the low-pressure cylinders are flat. This arrangement is very generally adopted, one reason being that with the flat valves there is less liability of leakage past them into the condensers. The side gear comprises the ordinary double eccentrics and links, with steam-starting as well as hand-starting gear. There is a cast-metal surface-condenser O to each set of engines, the circulating water passing through the tubes; the circulating pumps are of the centrifugal type, and designed to be each capable of discharging 600 tons of water from the bilge per hour with steam of 200 lbs. pressure per square in., and exhausting into the atmosphere. Balance weights are fitted to the high-pressure and low-pressure cranks, and on the trials of the ships there was found to be practically no vibration, there being complete steadiness of engines at all speeds. The propellers are three-bladed, of the modified Griffiths type, and the blades are of manganese bronze. Diameter of propellers 10 ft. 7 in., pitch at which set when tried 11 ft. 3 in.

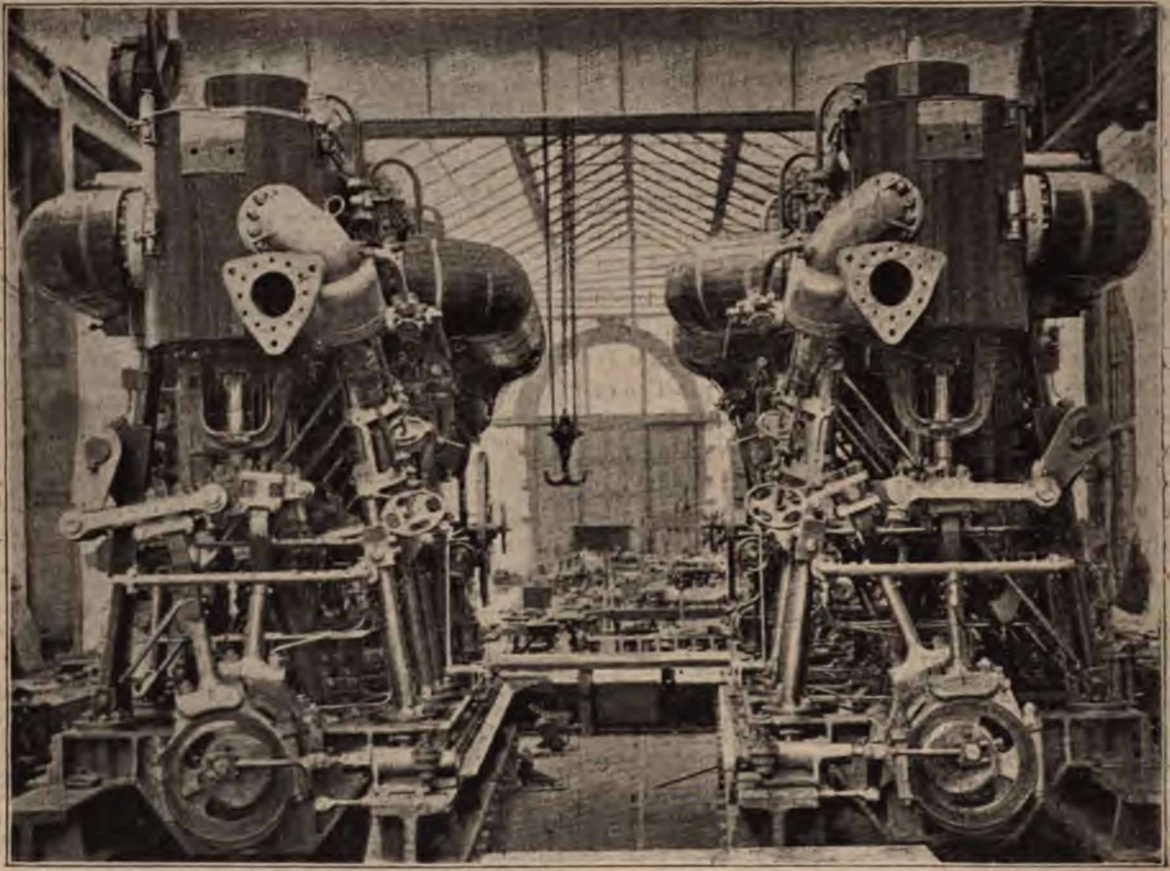
Boilers.—The general disposition of the boilers B is shown on Fig. 6 of the general arrangement of the machinery throughout the ship. There are two boiler rooms, containing eight water-tube boilers of the Thornycroft type, capable of being worked at a pressure of 300 lbs. per square in. The total area of fire-grate is 350·4 square ft., and the total surface of generating tubes is 19,515·5 square ft. The whole number of generating tubes in these boilers is 8,752, varying in diameter from 1⅛ to 1¼ in., the thickness of each tube being 0·116 in. All tubes are zinc-coated by electro-deposition on the outside, and are solid drawn by the cold process. The tubes are secured to the collector plates by the ordinary method of expanding. Water-pressure tests of 450 lbs. per square in. were applied to the boilers after manufacture in shop, again when placed in ship, and again after trials. Fig. 7 gives a view of one of the boilers as built up in the boiler shop. Four independent feed-pumps are fitted, two main and two auxiliary, all of the Weir type. The main and the auxiliary feed-pumps have independent systems of delivery pipes and feed valves, and the arrangements are such that each of the pumps is capable of feeding any of the boilers. An automatic feeding apparatus is fitted to each boiler, which, with the slow-moving feed-pumps, provides a very efficient arrangement for maintaining a strictly uniform water-level. Steel is the material used in the main leads of steam pipes, and the pipes are coated externally by electro-deposition of zinc.

---

*Read at the Plymouth meeting of the Institution of Mechanical Engineers. Sir William H. White, K.C.B., LL.D., in the chair.

Forced Draught.—There are eight fan engines F for forced draught purposes, which on the forced draught trials were capable of maintaining an air pressure of 3·7 in., with mean revolutions per minute 663.

Additional Machinery.—The machinery, apart from the main engines and boilers, comprises the following:—Two electric-light engines E, (Fig. 7,) one steering engine S, one capstan engine, two reversing engines, eight forced-draught fan engines F, four ash hoists J, one air compressor A, two main circulating engines C, two main feed engines M, two auxiliary feed engines X, two fire and bilge engines G, two hot-well engines H, two distillers D.



MACHINERY OF H.M.S. "PSYCHE," FIG. 1. VIEW FROM FORWARD.

Prior to the boilers being placed in the ship, one of the type was tested to ascertain if its evaporative power would meet the specified requirements, steam pressure being maintained at 300 lbs., and steam exhausting into the atmosphere at that pressure. Particulars of results were as follow:—

Area of fire grate	43.87 sq. ft.
Total heating surface	2,563·5 ,,
Steam pressure	300 lbs.
Mean air-pressure	3·2 in. of water.
Fan in use	1 in No.
Diameter of fan	5 ft. 6 in.
Revolutions of fan per minute	544.
Consumption of coal per hour	2,920 lbs.
,, ,, per sq. ft. of fire grate	66·56 lbs.
Thickness of fire	6 in.
Total water evaporated per hour ..	19,210 lbs.
Water per pound of coal from temperature of feed water	6·58 lbs.
Equivalent evaporation from and at 212°	8·10 lbs,
Temperature of funnel	841°.

As is usual with H.M.'s ships, on completion the machinery was subjected to a series of trials which were required to be carried out to the satisfaction of the Admiralty Inspecting Officers. These trials comprised the following:—(1) A basin trial; (2) a preliminary trial at sea; (3) a trial of 30 hours' duration at 3,500 I.H.P.; (4) trial of eight hours' duration at 5,000 I.H.P.; (5) a four hours' trial at maximum power, during which the power obtained was required to be not less than that specified nor more than 5 per cent. above it.

A summary of the results obtained on the trials of the two ships is as follows:—

THIRTY HOURS' TRIAL AT 3,500 I.H.P.

	Proserpine.	*Psyche.*
Pressure of steam at Engines ...	210	215
Vacuum in condensers, Starboard	25·7	26·3
,, ,, ,, Port ..	26·7	25·3
Revolutions per minute, Starboard	169·2	171·2
,, ,, ,, Port ..	168·3	170
I.H.P., Starboard	1,755	1,835
,, Port	1,889	1,811
Total H.P.	3,644	3,646

EIGHT HOURS' TRIAL AT 5,000 I.H.P.

	Proserpine.	*Psyche.*

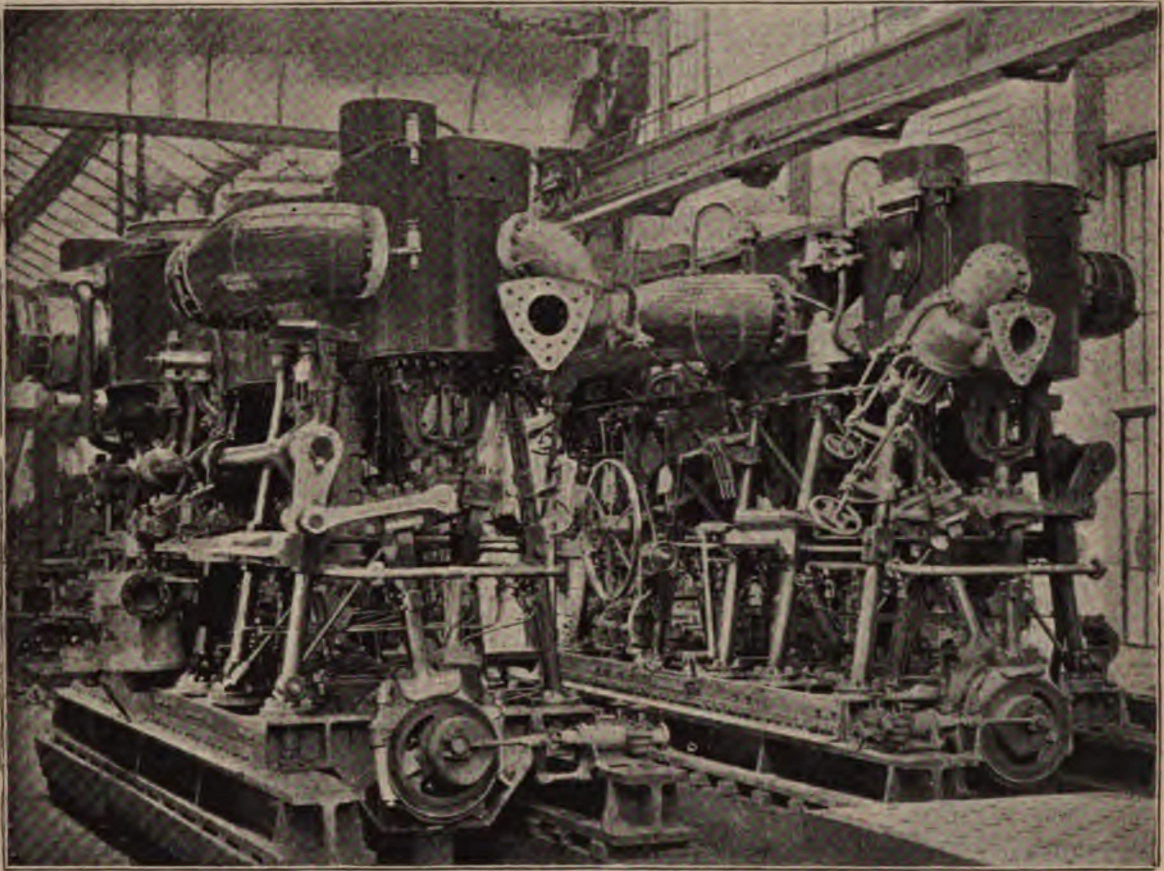
Total H.P.	7,145	7,031



MACHINERY OF H.M.S. "PSYCHE," FIG. 2. VIEW FROM FORWARD.

The usual stopping and starting trials to test handiness of machinery were satisfactorily carried out, and all auxiliary machinery tested to ascertain its full compliance with requirements. An important condition attending these trials is that the water in the boilers must remain fresh throughout. It was required that, should there be any admixture of sea-water, the cause must be ascertained and the trial repeated after the necessary adjustments have been made. The freshness of the boiler-water and feed-water is determined by the nitrate of silver test, and by the use of a special sensitive hydrometer. Also on the thirty hours' trials at 3,500 I.H.P., it was required that all losses of fresh water caused by steam and water-leakage should be made good by the evaporating plant.

On conclusion of the trials above enumerated, the machinery was opened up in the usual manner for examination and for the satisfaction of the inspecting officers. Also a water-pressure test of 450 lbs. per square in. was applied to the main and auxiliary steam pipes, and all joints were found to be perfectly tight. The low-pressure cylinder-jackets were also tested to 150 lbs. pressure with similarly satisfactory results.

The opening up was satisfactory, and everything appeared to indicate durability and efficiency.

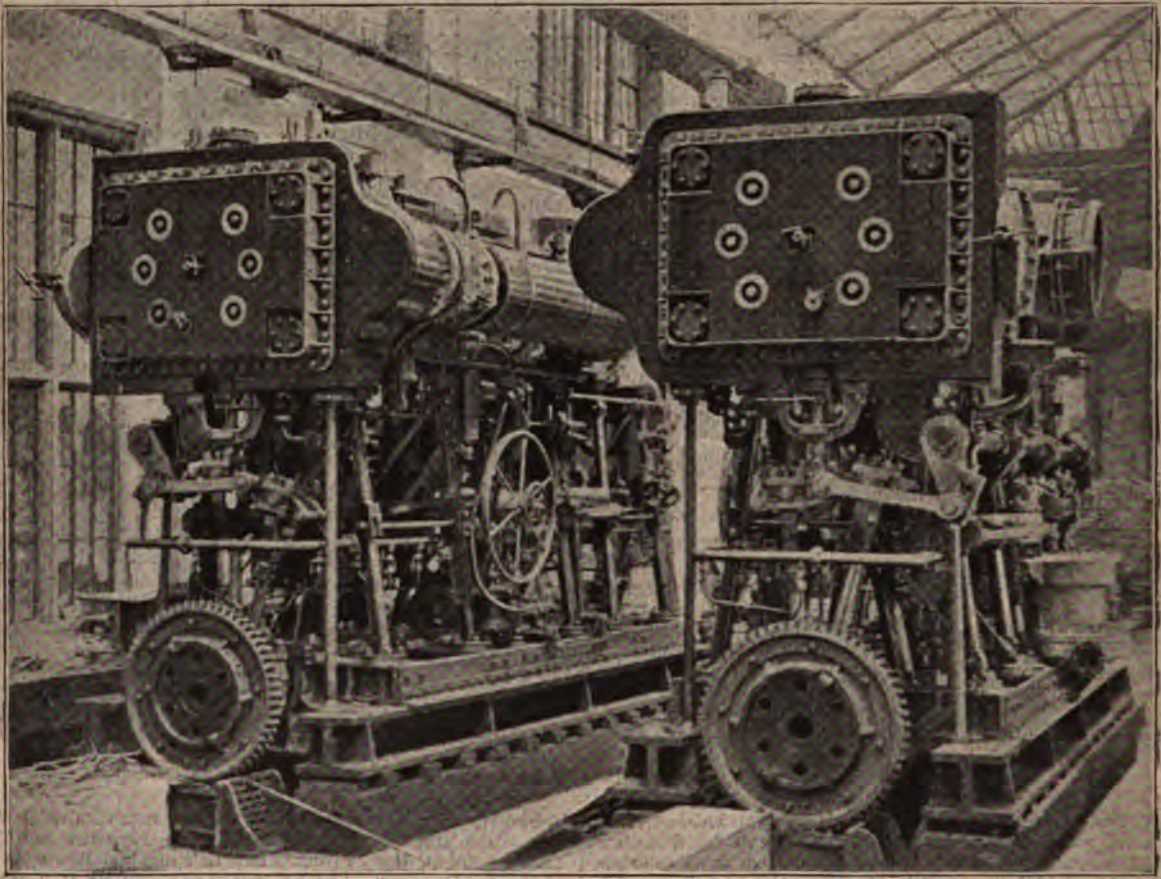
Further Trials.—Subsequently to the opening up and after the ships were commissioned, a further trial of three hours' duration took place; the power authorised was 5,000, and the following were the results obtained :—

	Proserpine.	*Psyche*
Pressure of steam at Engines ..	239	235
Vacuum in condensers, Starboard	25	27·8
" " " Port ..	23·8	25·2
Revolutions per minute, Starboard	186·5	195·8
" " " Port ..	186·5	194·2
I.H.P., Starboard	2,501	2,609
" Port	2,600	2,538
Total H.P.	5,101	5,147

Shortly after the completion of the commissioning trials the ships left England for the North America and West Indies Station, the *Proserpine* last year and the *Psyche* in May of the present year. The procedure as regards these two ships was practically similar to that carried out in all new ships, and illustrates the tests to which machinery is subjected before being finally accepted by the Admiralty, whether the machinery has been manufactured by a private firm or at a dockyard, and before the ships are permitted to depart on home or foreign service.

Training of Engineer Students.—The *Psyche's* machinery, as well as that for other ships previously constructed or now under construction at Keyham, has afforded excellent opportunities for the efficient training of the engineer students, who are being instructed both theoretically and practically to enable them to become engineer officers in the Royal Navy. For the last 11 years Keyham has been the only Admiralty training ground for these officers. The number of students at the present time is 192. An entry is made once each year, during the first or second week in July, following a competitive examination held by the Civil Service Commissioners in the previous April. The period of training is five years. Throughout this time they undergo an educational course at the Royal Naval Engineering College under Professor Worthington, whilst their practical training is obtained in the dockyard at Keyham, and the work they perform is as far as possible real. They take a considerable part in the repair and manufacture of machinery, and in the cases of the two ships which have formed the basis of this paper they have had a very large interest, more so in the *Psyche*, for the reason that they have been able to follow the manufacture of her engines and boilers right through to the time of the ship going to sea, whereas in the *Proserpine*, as previously mentioned, the engines and boilers were sent to Sheerness to be fitted in that ship, and the experience to be gained by seeing them fitted on board was not obtainable.

As illustrating the part taken in the manufacture of new machinery, reference need only be made to that of the *Psyche*, and the following work was entirely carried out in the engineer students' fitting shop:—The two surface-condensers were tubedand tested; the two fire and bilge engines, eight fan-engines, two hot-well engines and pumps, two circulating engines and pumps with auxiliary air-pump, and the two reversing-engines in connection with the slide-valve gear, were completely fitted up from the rough forgings and castings, including all machine and fitting work. In addition, a large number of minor fittings, such as cocks, valves, &c., passed through the hands of the students. It should be noted that the work just enumerated is an indication of what is performed by the students in the early part of their training, that is, during the first half of it, and its class is such as to offer every possible attraction for a student commencing a marine engineering career; at least this is the object aimed at, and, judging by results, there is every reason to assume it has been successfully attained.



Machinery of H.M.S. "Psyche," Fig. 3. View from Aft.

Fig. 8 is a plan of the workshops at Keyham, showing the position of the fitting shop appropriated for the training of the engineer students relatively to the principal fitting shops of the *chief engineer's department*. It will be seen that they are so close that the students are enabled to watch any erection of new machinery; in fact, it is part of their instruction to be shown the nature of the work as it progresses, and they are afforded every facility.

It may be of interest to give the exact training an engineer student undergoes at Keyham during the five years he is under instruction preparatory to his appointment as an assistant engineer, Royal Navy.

First year's Training.—On entry he is engaged on practice work with the hammer and chisel, and after a short time commences engine fitting (useful work).

Second year's Training.—For nine months he is employed at the lathe, and the remaining three months at other machines. During the second year a half-day per week for the greater part of the year is spent in sketching details of machines and parts of machinery.

Third year's Training.—Eight months are spent n engine fitting in the students' shop, one month he is sketching details and learning the principles of construction of machinery used in connection with the discharge of torpedoes, such as air-compressing machinery, torpedo tubes both submerged and above water (the latter as made and placed on board the *Psyche*), and the remaining three months he is employed on repairs to engines, &c., of ships afloat, or as the opportunity presents itself, such as in the case of the *Psyche*, in fitting new machinery in ships.

It may here be observed that the testing machine for materials is placed in the students' fitting shop, and arrangements are made for the students in turn to become acquainted with the tests and the methods of carrying them out and of recording them, all very important matters in connection with an engineer's training. All the materials used in the manufacture of the *Psyche's* engines were so tested in order to ascertain if they complied with requirements as laid down in specification; for

instance, in the case of the gun-metal used the tensile strength must not be less than 14 tons with an extension in 2 in. of length of 7½ per cent., and in the case of high-tension cast bronze such as used for the *Psyche's* propeller-blades the tensile was not to be less than 28 tons with 15 per cent. extension.

Fourth year's Training.—The first six months are a continuation of the last three in the previous year, followed by one month in the coppersmiths' shop, where the short time renders it necessary their work should be more or less of a practical character, such as fitting patches, branches, and flanges, soldering and brazing, becoming acquainted with the method of running white metal into bearings and making sketches of the principal apparatus and processes generally appertaining to coppersmiths' work. This is followed by one month at smithing, in which the work is also of a practical character, such as welding and light forging. Then follows one month in each of the pattern shop and brass foundry, and two months in the boiler shop, in the last of which he obtains knowledge of riveting, tube rolling, &c.

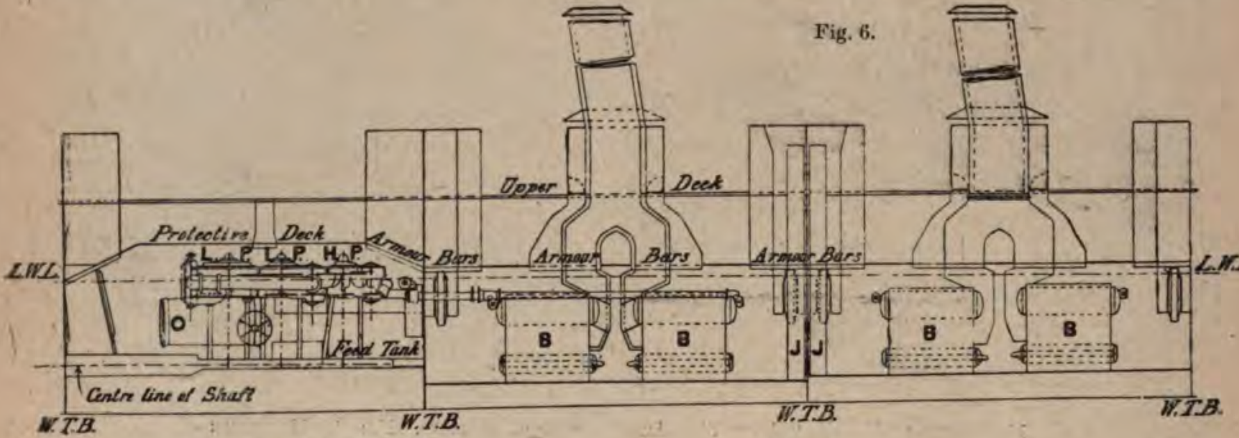

Fig. 6.

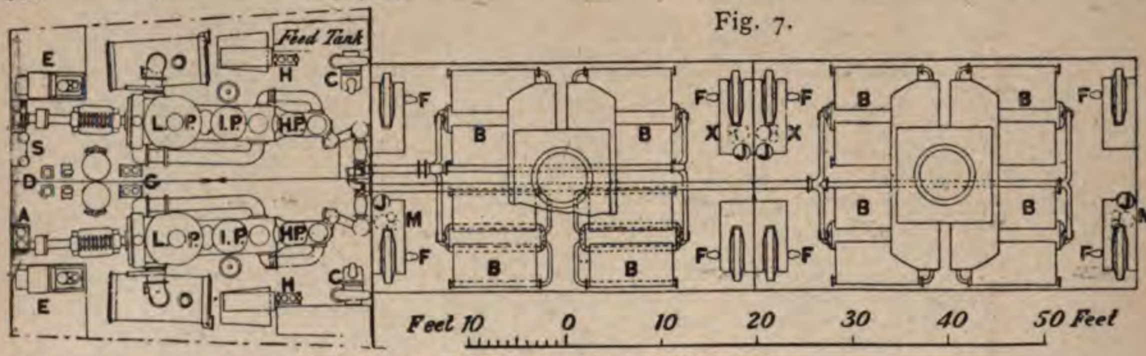
Fig. 7.



MACHINERY OF H.M.S. "PSYCHE." GENERAL ARRANGEMENT.

With reference to the boiler shop there are invariably new boilers under construction, and all descriptions come under repair or observation. At the present time Belleville boilers are being manufactured for the *Vestal*, and tubes are being prepared for boilers of the small-tube type already in existence, including the following descriptions: Thornycroft, Yarrow, Reed, Mumford, Blechynden, Du Temple. Also the Babcock and Wilcox boiler is under observation. During the third and fourth years one evening a week for two hours is appropriated for instruction in drawing under the direction and supervision of experienced draughtsmen.

Fifth year's Training.—One month in the pattern shop and one month in the foundry similarly to fourth year, doing useful work. Three months' fitting on ships afloat. Two months are appropriated for obtaining some acquaintance with the elementary principles of ship construction and the fittings of ships. The remaining five months are spent in the drawing-office learning engine drawing and design, the latter part of the time being occupied in the preparation of a drawing from his own sketches, which drawing is required to be done to enable him to pass into the Navy.

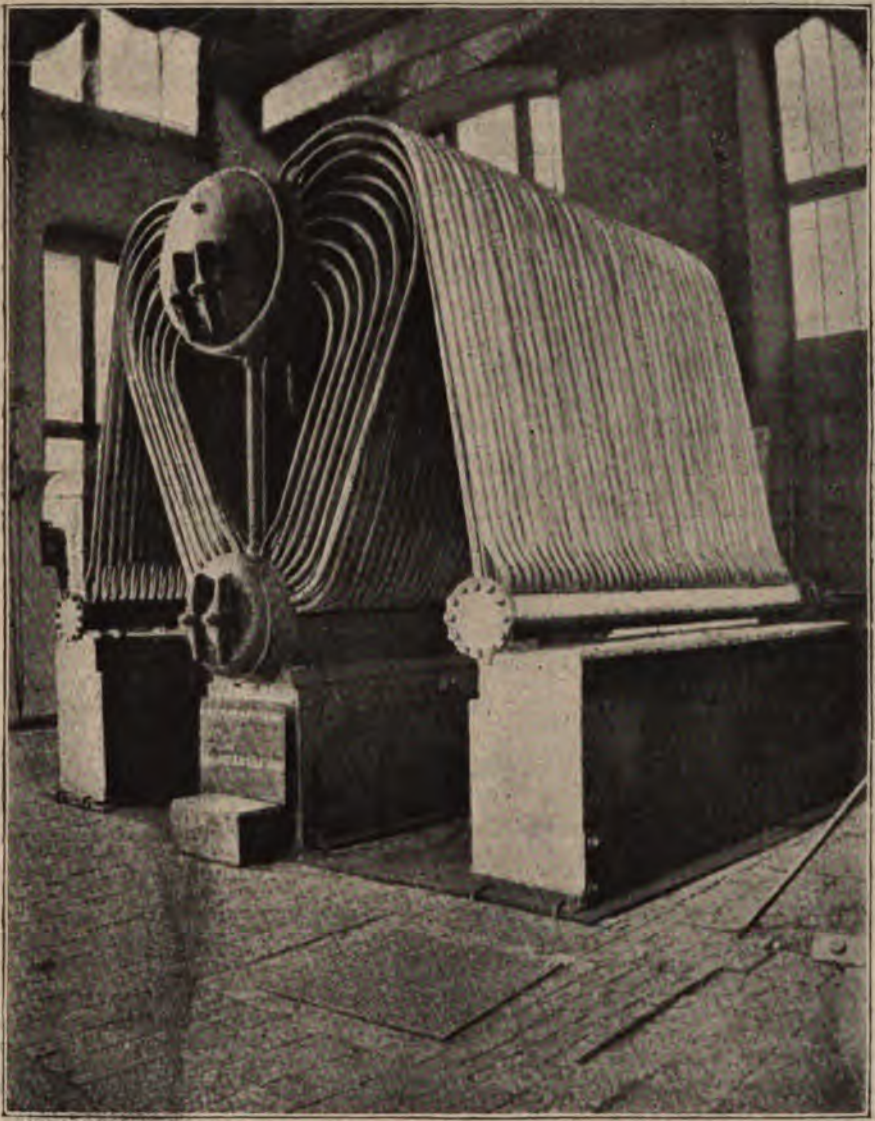
In order that the students may become acquainted with the working of machinery and the duties connected with the engine room when under way, the Admiralty have set apart H.M.S. *Sharpshooter* for the purpose, and classes are taken from March till October. During March the ship steamed in the basin, and each third-year student is afforded the opportunities of actually performing the operations of laying and lighting fires, getting up steam, opening and regulating the various valves, attending to the working of the engines and boilers, and learning the various duties of the engine room. The third-year students are divided into four classes, the course for each class lasting one week, four days under steam, the remaining two days for repairs, examination, &c. From April 1st to September 30th (except during examination and vacation times) the *Sharpshooter* is steamed under way by fourth and fifth-year students on two afternoons and one whole day a week, when all duties connected with the working of the engines and boilers and examination and repairs after steaming, are carried out by them. Each student by the end of his fifth year has passed through, in addition to the preliminary stage in the third year, four courses of steaming under way, each course of two weeks' duration.

At the end of the season the ship is laid up for repairs, which are largely effected by the students themselves during the winter months.

It should be noted that the *Sharpshooter* has triple-expansion engines and was the first ship in H.M. Navy to be fitted with Belleville boilers, so that the steaming instruction afforded the engineer students by this ship is of very modern character.

Lectures on marine engineering are given to the various years by officers of the chief engineer's department at Keyham, 18 per annum to the fifth year and 12 to each of the other years. The time devoted to the *Sharpshooter* and to lectures is taken out of the students' working hours in the dockyard, which comprise four forenoons and five afternoons; the two remaining forenoons are devoted to educational subjects distinct from the dockyard and under the direction of the headmaster.

Sir William H. White, in his presidential address, delivered to this institution in April last, gave the various descriptions of machinery with which the modern warship is now supplied, and it goes without saying that with the growth of this machinery the necessity has increased for giving the officers who will be mainly responsible for its efficiency every opportunity for becoming familiar with it, and of becoming up-to-date naval engineers.



Machinery of H.M.S. "Psyche," Fig 8. One of Boilers.

The facilities afforded at Keyham for the acquirement of a thoroughly practical training place the Royal Naval Engineering College in the foremost rank as an institution for obtaining a sound knowledge of mechanical engineering. The fact that as soon as possible after entry the student is employed on useful work, the various courses of instruction which are arranged to render the knowledge of marine engineering obtained as complete and as comprehensive as possible, the facilities afforded for acquaintance with running machinery, the constant contact throughout the training with experienced workmen, the frequent opportunities afforded for obtaining information from the officers who have charge of the training, all go to indicate that nothing is spared to make the training of the engineer student as complete as possible.

It has been thought that the subject could be best placed before the members of the Institution of Mechanical Engineers by associating the manufacture of the machinery of H.M.SS. *Proserpine* and *Psyche*, in which the students themselves have had considerable interest, with a description of the training undergone. It only remains to say that a better idea can be obtained by a personal inspection of the workshops at Keyham and the Royal Naval Engineering College itself, and that it will be considered a privilege to give the members of this institution any further information desired.

Hartmann's Rahtjen's Improved Composition.—The latest additions in the way of first-class battleships for her Majesty's Navy, namely the *Venerable*, *London*, and *Vengeance*, are coated with Hartmann's Rahtjen's Improved Composition (The Red Hand Brand).

Messrs. Denny & Brothers have been commissioned by the Russian Volunteer Fleet to build and engine a twin-screw steamer for passenger and cargo service, and of high speed. The new vessel, which is to be named the *Poltara*, is to have water tube boilers of the Belleville type, four cylinder engines, and is to have a speed of close on 20 knots. The cost of the vessel, which is to be ready for delivery in the spring of 1901, is estimated at 3,000,000 roubles or about £450,000.

THE FLEETS OF THE MAIL LINES.

(From our own Correspondent.)

The Paris

is indeed an unlucky ship. After spending about two months in provisional repairs at Falmouth, it was decided that she should go to Milford Haven for the purpose of being dry-docked and so having the real extent of her injuries ascertained. This seems to be the last straw in the ship's misfortunes, for Milford luck is by this time almost proverbial. Anything that goes to that port seems to leave its good fortune behind it. We have just seen an example of this in the case of the Canadian Steamship Company and their unlucky *Gaspesia*. Perhaps it may be in the case of the *Paris* that it will be a change for the better. At all events it is said that the vessel is less damaged—as far as can be seen—than the most sanguine dared to hope. She started on her voyage from Falmouth on the morning of the 14th August in tow of three salvage boats. On getting clear of the harbour she was able to use her own engines in aid of the tugs. The flotilla passed the Lizard shortly after noon on that day, and reached Milford shortly before mid-day on the 15th. On Friday, the 17th, she was safely bestowed in a wet dock.

Attention may well be directed to a case recently tried before the judge of the Falmouth County Court. It arose out of the stranding of the *Paris*, and was a salvage suit brought by certain local pilots for services rendered to that liner on the night when she took the rocks. The claimants alleged that they saw the *Paris* coming full speed for the Manacles rocks. They signalled to her as well as they could, and she thereupon altered her course so that, instead of striking as did the ill-fated *Mohegan*, she ran on to Lowland Point, where, as the event has proved, salvage was possible. The claim was defeated; for the officers asserted that they took no heed of the signals, believing themselves miles away from any danger, and it was decided that the coincidence of the waving of the pilot boat's light and of the steamer's alteration of course was quite fortuitous. The navigating officers of the *Paris* said they took the signals for the customary pilot signals, which in the ordinary course are constantly displayed to such vessels, and as constantly disregarded by those who do not need the services proffered. The rights and wrongs of the case itself do not seem to be very important, save to those immediately concerned; but it certainly would appear that from this and other cases within one's recollection there is a need for some simple and unmistakable signal which shall convey at once to a fast moving steamer the fact that she is running into danger. In more than one recent case the existence of such a method of communicating a warning would have averted enormous loss of life and property.

The Gorsedd,

of Cardiff, a fine large steel cargo boat, which was stranded at Ile de Seine at the end of July—though only built on the Clyde in 1894—had previously encountered serious trouble. She sailed from Kutchinobzu in November, a year after her launch, on a voyage to Port Townsend, and encountered very heavy weather. She was so seriously delayed that as much as sixty guineas premium was paid for reinsurances in respect of her ere she was reported. Meanwhile, in a gale which she encountered a week after her sailing, no less than 57 of the tubes in her boilers had burst.' When Mr. William Allen and those who are with him speak of the failure of the water-tube boiler, they should remember, or, if they never knew of the fact, should be told of, such experiences as these with the present Scotch type to which he is so superstitiously devoted.

MACHINERY OF H.M.S. "PSYCHE." PLAN OF KEYHAM FACTORY.

The White Star Line

has disposed of its steamship *Belgic*—second of the name—and she has passed into the hands of the Atlantic Transport Company. Her new name is *Mohawk*, and she is appointed to take the outward sailing from London to New York for her new owners on the 7th September. The vessel in question when new made a voyage or two on the Atlantic, but she has been employed almost the whole of her time in the San Francisco, Yokohama, and Hong-Kong service, where she acquired some considerable popularity. She was built at Queen's Island in January, 1885, and is—as were other vessels of her date—a single screw with engines of the compound type. Her gross tonnage is but 4,212 tons, so that she is somewhat smaller than the general run of Atlantic Transport Liners.

The *Oceanic* arrived at Liverpool on the 26th August, and will make her first departure from the Mersey on the 6th September. Very little has transpired as to her internal arrangements down to the time of writing. The decoration of the public rooms is said to be exceptionally fine, and the builders have again followed the arrangement adopted in the *Majestic* and *Teutonic*, whereby the library is placed above the saloon, with a large ground-glass tableland in its centre covering the usual central dome. The saloon is a very large room, being capable of seating no less than 400 persons at once. There has been a great deal of attention paid to the geography of the ship, as indeed is most necessary when dimensions are so large, so that the minimum of running about may be given to the stewards. There has also been made exceptional provision for the accommodation of the wealthier class of travellers. For American millionaires there are luxurious suites of cabins, and even, in this department, a subsidiary corridor of maids' rooms, so that their private attendants may always be within call of the lady travellers.

The *Medic*, which inaugurated the service from Liverpool to Australia for the White Star Line on the 3rd August, took out a very satisfactory amount of cargo and a good number of passengers. She is to be followed on the 7th September by the sister ship *Afric*, which vessel has already made a trip to New York and back early in the present year.

Southampton

is contemplating the further expenditure of money at the docks, though, as far as can be seen, local capitalists do not directly engage in the development of the port. The latest scheme is the building—by a company subsidiary to the South-Western Railway—of a warehouse with cold storage to the extent of 21,730,000 cubic feet. The idea is that the port should obtain a large proportion of the dead meat, fruit, and cattle trades. As regards cattle and dressed meat the promoters state that they have obtained promises from importers and shipping companies that they will make Southampton their headquarters when the company is ready to commence its operations. They believe as regards fruit that they have two strings to their bow. One is the preserving in cold storage, till favourable opportunities, of the fruit which already comes to our markets and of which there is a glut during a few weeks in the year. The other is the dealing with that which is to come from the West Indies in place of the sugar which can be no longer be grown there at a profit. As reported,

The West India Mail Contract

comes to an end at the end of June next. Already tenders for the execution of a new service are being sought by the Post Office, and it may very well be—in view of the arrangements which are being made for fruit lines from these colonies—that a very radical alteration may be made in the conveyance of these mails and in the Royal Mail Company's relation to the Post Office.

Under the title of

A Big Deal,

we last month mentioned the sale by the New Zealand Shipping Company of four of its vessels to the British India Steam Navigation Company. This is not the only large operation in which the companies with which Sir Edwyn Dawes is concerned have recently been engaged. His New Zealand Shipping Company has by tender bought from the liquidator of the Canadian-Australian Royal Mail Steamship Company, Limited, as a going concern, the fleet, good-will, and other property of the business in liquidation. The three steamers comprised in the fleet are the *Miowera* and the *Warrimoo*, both specially built for the service in 1892 at Newcastle by Messrs. C. S. Swan & Hunter, and the *Aorangi*, a vessel built nine years previously by Messrs. John Elder & Company, of Fairfield, for the New Zealand Shipping Company itself. The whole has changed hands at the price of £145,000. We find on looking into the statement of accounts of the Canadian-Australian Line that the cost of the *Warrimoo* and of the *Miowera* was £75,000 each, and that the *Aorangi* when new cost £127,000. She cost the defunct company, however, but £35,000. On obtaining her they had her re-engined and reboilered, and practically rebuilt in her passenger accommodation. What the exact cost of these improvements and of sending her out to her station may have been, it is difficult to say; for the official receiver put it at £67,000, whilst Mr. Huddart corrected the figures and wrote that the loss on her at the time the company went into liquidation was but £6,000 or £7,000. At all events, the *Aorangi* seems to have been a very costly purchase to the Canadian-Australian Line. It is reported that the New Zealand Shipping Company is ordering four 10,000-ton steamers to replace the four it has sold to the British India Company.

The Dominion Line

seems to have entirely captured the best class of passenger traffic between Liverpool and Boston, for they have made three sailings out of every four during the present season with the magnificent twin screw-steamships *New England*, *Canada*, and *Derbyshire*. These are far finer and faster than anything else that frequents the Massachusetts port. They have long ago secured the speed record which the Cunard Line had obtained when it ran the *Servia* and *Aurania*—now running as extra New York boats on the route. The *New England* at the end of July beat her own westward record, lowering the time of passage to six days, seven hours, and forty minutes, and on one day doing 440 nautical miles as her run. This is equal to a speed of upwards of 17·8 knots. Against her were running for the premier Atlantic line the *Ultonia*, which, starting two days before her, got in one day after her, and the *Pavonia*. The latter sailed five days later, and was nine and a-half days over the crossing. It would seem that the old *Samaria*, which is still employed in their Mediterranean service, is not the only vessel that is waiting to be disposed of out of the Cunard fleet.

The Allan Line

has now its *Parisian* at work again. Her appearance has been altered by the substitution of a single large funnel for the two with which she was formerly fitted, and her speed has been materially increased by the improvements in her engine and boiler rooms. The line has further been reinforced by the addition of the *Bavarian*—a fine twin screw-steamship of over 10,000 tons gross register, built and engined by Messrs. Denny & Company, of Dumbarton. This vessel arrived at Liverpool from her builders on the 17th August, and started on her maiden trip to the St. Lawrence on the 24th August. This vessel is remarkable from the fact that she is the first instance of the adoption of the twin-screw principle by the Allan Line. It is true that these owners have in their fleet three vessels, the earliest Atlantic steamships so constructed. But they were not built to their requirements, and their possession did not in any way bind the line to the approval of the principle. The *Bavarian*, on the other hand, must be in every way held to embody the ideas of what a mail and passenger ship for the St. Lawrence trade should be in the eyes of those who have by far the longest experience of the trade and who have shown themselves most conservative in their ideas.

The Elder, Dempster Company,

which has now the Canadian mail contract, is running the *Arawa*, once the crack vessel in the New Zealand trade, in its mail service from Bristol *via* Queenstown to Montreal, whilst Messrs. Allan have her sister ship, the *Tainui*, in their mail line.

Dock Extensions

seem to be the general rule in all directions. There is talk of further extensions at Liverpool, and of the removal of the timber trade headquarters from the Canada Dock—displaced thence by dock enlargements—to Wallasey. At Barrow a gigantic graving dock is to be built. Its length will be nearly a thousand feet, and its entrance a hundred feet wide, with a depth on the sill of 30 ft. The entrance to the Ramsden Dock is to be deepened from 24 to 30 ft.; but, as this latter work is to be completed before the graving dock is to be undertaken, it will be some time before the dry dock will be ready to be occupied.

Changes in Shipping and Shipbuilding Concerns.

Not only are vessels themselves being shifted about from one ownership to another, and back again, with a frequency which makes it very difficult to keep in touch with their movements, but the companies themselves are also constantly changing. Quite recently the Sun Shipping Company—whose managers are Messrs. Robert Alexander & Company, of Liverpool—has been absorbed by the Hall Line, which is under the same management. Now the Gulf Line, Limited, has been formed to acquire the businesses of the Greenock Steamship Company, Limited, and of the Gulf Line Association, Limited.

The "Gaspesia."

The prospects of the crew of this unfortunate vessel look a little brighter since last we wrote. The Supreme Court of Newfoundland has reduced the amount payable as salvage to the owners of the steamship *Kite* to 2,500 dols., whilst the vessel herself has been sold by the court for the sum of 27,000 dols. We may fairly hope that out of the proceeds there will be something left for the claims of the men who worked and suffered in her for so many months, and whose claims were so powerfully set forward in the letter of her chief engineer.

The Engineers of the Steamship "Kennett"

have distinguished themselves by a remarkable repairing job. The vessel in question is of about 1,700 tons gross register, and is fitted with triple-expansion engines of 188 N.H P. Having broken her propeller shaft in the Atlantic, an attempt was unsuccessfully made to fit a spare screw which was stowed on board. The failure to carry out this effort only spurred them to fresh exertions. A new propeller was manufactured from plates and doors in the ship, and eventually fitted to the remainder of the shaft. Sixteen days were consumed in the work; but so well was it done that the ship was enabled to traverse a distance of 1,200 miles under her own steam, and thus to make the island of Barbadoes without taking assistance.

The Norddeutscher Lloyd

still goes on increasing its fleet. The *Koln*, one of three sisters for the Baltimore service, has just been launched at Bremerhaven. Now another 10,000-ton twin-screw-steamship is ordered for the New York Line from the firm of J. C. Tecklenborg & Company, of Geestemunde. A paper published some few weeks ago by the company gave the following list of vessels under construction:—

For the New York Line:—Grosser Kurfurst, gross tonnage, 12,500; *Rhein*, 10,000; *Main*, 10,000.

For the Australian Service:—Konig Albrecht, gross tonnage, 10,000; *Prinzess Irene*, 10,000.

For the Baltimore Service:—Koln, gross tonnage, 7,500; *Frankfurt*, 7,500; *Hannover*, 7,500.

For the East Asian Line:—Strassburg, gross tonnage, 5,000; *Wurtzburg*, 5,000.

For the North Sea:—Nixe, gross tonnage, 800.

Eleven vessels in all, comprising 85,800 tons, an average of 7,800 tons per bottom. The aim for the New York express service, of course, is to run it with the four vessels, *Kaiser Wilhelm der Grosse*, *Kaiser Friedrich* (when her builders get her right), *Kaiserin Maria Theresa*, and this *Grosser Kurfurst*.

The *Fulda* may be struck off the list of the fleets. She has been found irreparable after her accident in the Birkenhead Dock. At Bremerhaven she was dismantled and deprived of her engines, and the sheer hulk has now been towed to a German outport for dismemberment. Her sister, the *Werra*, seems no more likely than she ever was to see the port of Paspebiac, for which the Canadian Steamship Company, Limited, had destined them. The purchase was never completed and the *Werra* has been again offered for sale at Liverpool, which she left on the 25th August; but no satisfactory bids were forthcoming.

Canadian Steamship Lines.

The present season has seen the discontinuance, for a time at least, of two Canadian lines. One of these, of course, is the Canadian Steamship Company spoken of above. The other is the Beaver Line Associated Steamers, of which Messrs. D. & C. MacIver were the managers. As mentioned in a recent issue, they lost some time ago the "Lake" boats, which were sold with the name of Beaver Line and the goodwill of the old Canada Shipping Company to Messrs. Elder, Dempster & Company. They, however, were not to be beaten by that. They went on with the *Gallia* and the *Tongariro* under the title which we have quoted. Then the *Gallia* left them, and was replaced by the *Ruapehu*. But she was not long employed. The sailing for the 10th of June was not made, and no further dates have been advertised.

The Kaiser Friedrich."

Since the above was in type it has transpired that she will not run again for the Norddeutscher Lloyd, but will be taken over by the Hamburg-American Line.

CRAWFORD'S PATENT WATERTIGHT BULKHEAD DOOR FOR SHIPS' HOLDS.

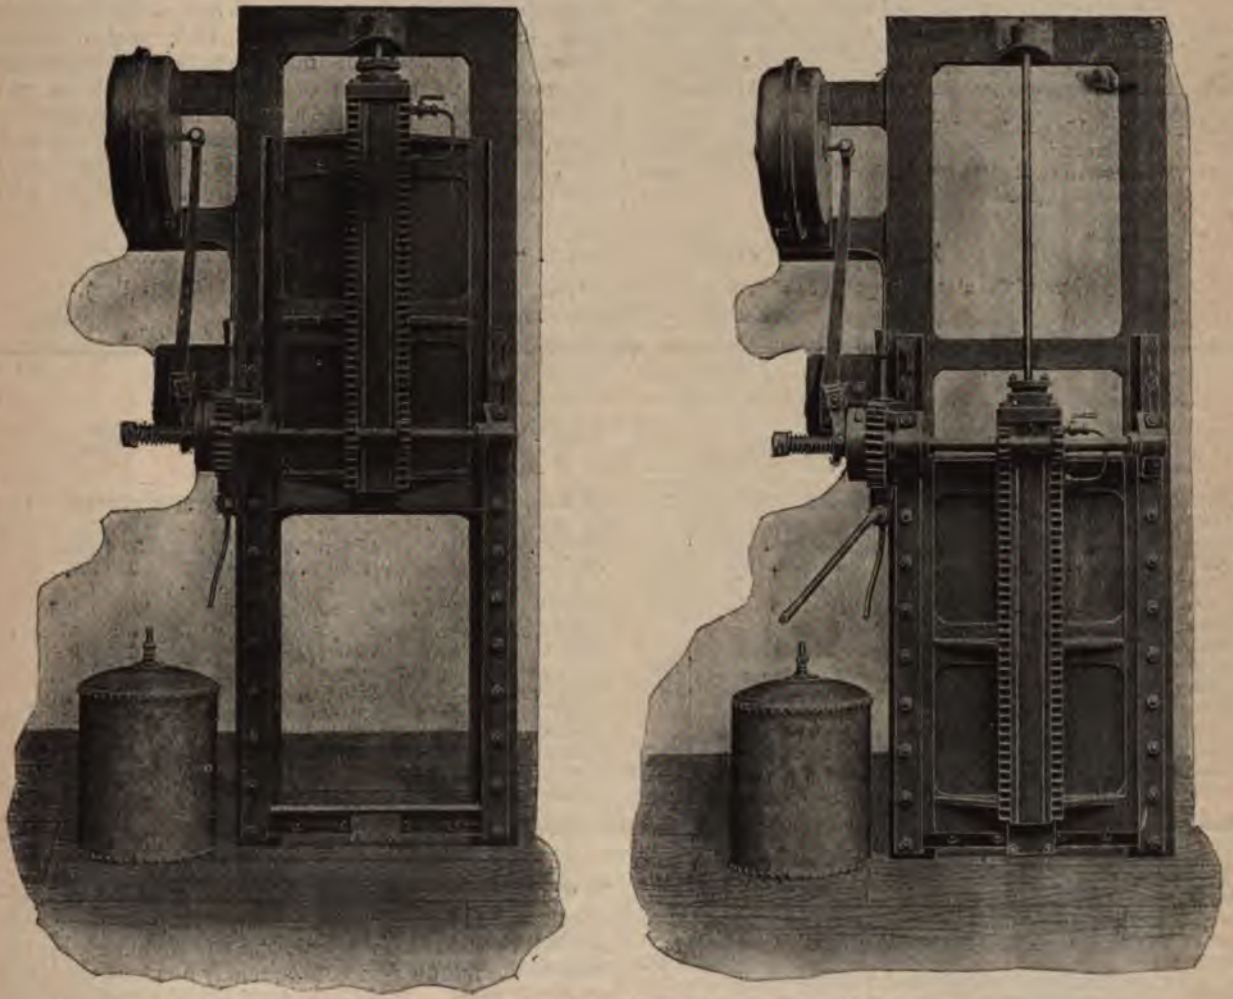
THE accompanying illustrations show the "Crawford" patent automatic watertight bulkhead door for the holds of ships—one of the latest, and probably one of the most promising, of the many inventions of this kind put before the shipbuilding and shipowning worlds within recent years. It is claimed for it that it is automatic in a truer sense than in any door yet invented, in that it requires neither the action of man, electrical or other appliances, to make it effective at the critical moment, the automatic action in its case depending upon the pneumatic force produced, in the special device provided, through the inrush of the sea to a vessel's bilges in the event of an accident to the shell.

The illustrations given show the door in the open and the closed position respectively, and with their aid only a few sentences of description are necessary to convey a clear understanding of its working. Whilst the special feature is its automatic character, the door can, of course, be operated by hand from the deck, or otherwise if desired. First, as to the action of the door, and the gear in connection, when automatically operated on. Assuming the vessel's shell to have been pierced, either through striking on rocks or from other cause, the inrush of water into the bilges of the vessel enters the galvanised iron air-vessel, or chamber, there situate (shown to the left of our illustrations). The compression of air in this chamber caused by the rising water is carried up a small copper pipe leading to one side of an elastic metallic diaphragm, shown alongside the upper framework of the door. From the centre of this diaphragm, on its opposite side, projects a pin, attached to a vertical lever, which, at its lower end, actuates a clutch, throwing in or out of gear the shaft and gear by which the door is raised. The air-compression, acting on the diaphragm-pin and lever, withdraws the clutch, and the door is free to fall by its own weight.

The diaphragm is only about 15 in. outside diameter, and is extremely sensitive, as may be judged from the fact that it operates, and the door falls, when from 6 in. to 10 in. of water enters the air-chamber. The air-chamber itself is only about 12 in. in diameter, and, of course, can be made in any shape or form to suit each individual requirement.

In order, however, to minimise the risk of life and limb being endangered, as they so often are by the sudden sharp fall of a heavy door, and also with a view to giving the crew in the holed compartment of the vessel a better opportunity of effecting their escape, a retarded motion is imparted to the door for the greater part of the period of its fall. This is effected as follows:—To the door is attached a cylinder filled with oil, fitted with stationary piston-rod and piston, secured at its upper end to the bulkhead, the piston having a hole bored through the same, the size of the hole regulating the speed at which the door falls. A by-pass pipe, which may be seen fitted at the top of the cylinder (or an enlargement of the diameter of cylinder), permits of the easier passage of the oil to the other side of the piston, thus allowing the door to fall *sharply* into its closed position when about six inches from the bottom.

Whilst the door is being raised by means of a portable handle (or wheel), the powerful long spiral spring, seen to the left of the clutch, immediately presses the latter into position, thereby putting into action the horizontal shaft, thus raising the door by means of the rachets (seen on each side of the cylinder, but which have in later-made doors been put on each side-frame of the door as being a better arrangement). The usual deck connections, as has been stated, are fitted. The automatic arrangement here described can be adapted to existing doors.



Crawford's Patent Watertight Bulkhead Door for Ships' Holds.

We understand that several large liners at present under construction are having "Crawford's" patent doors fitted, and that they are likely to be freely specified in future by some of our largest steamship companies.

A full-sized door has been shown in the Glasgow Royal Exchange and elsewhere, and one can be seen working on application to Messrs. William Christie & Co., 70, Wellington Street, Glasgow, who are the sole agents for the sale of the Crawford patent door.

Messrs. W. Thacker & Co. will issue in the early autumn "The Imperial Russian Navy," which is the title of a forthcoming book of reference by the well-known naval author and artist, Fred T. Jane, and will be issued simultaneously in England and America. Mr. Jane, who has recently returned from St. Petersburg, where he was the guest of the Grand Duke Alexander Michaelovitch, a captain in the Russian Navy, was given exceptional facilities for visiting the Imperial dockyards and Arsenals. The book, which will deal with the past history of the Russian Navy, its present position and its future, will be copiously illustrated by the author. The book will contain: Chronological history of the Russian Navy from the days of Rurik's attack on Constantinople, A.D. 865 to the present day, with photographs of all modern ships, and full descriptions; the Russian dockyards and shipbuilding programme; the personnel, armament, equipment, and drill of the fleet; and a variety of other interesting naval matters.

We have received for our inspection a series of pictorial post-cards of typical British war ships from original pictures executed specially for this series by Mr. Fred. T. Jane the celebrated naval artist. These cards are reproductions in no fewer than 12 colours; they are considered the finest examples of chromo lithography in this class of work yet produced, and being retailed at the extremely low price of 1s. per series of 12 cards ought to command a large sale amongst both naval and marine engineers, and others who are engaged in maritime pursuits. They are published by Mr. A. Ritchie Leask, 95, Minories, London, E.

WESTERN AUSTRALIAN COAL PROSPECTS.

AN important report has been received from Rear-Admiral Pearson, through the Governor of Western Australia, Sir Gerard Smith, K.C.M.G., by the Agent-General, the Hon. E. H. Wilkinson, to the effect that he has tried 100 tons of Collie coal on board H.M.S. *Royal Arthur*, at the request of the Government of the colony, and compared it with the coals of Westport (N.Z.), Metropolitan (N.S.W.), and Lithgow (N.S.W.). He says, "the Collie coal is a rapid-burning, wood-like coal requiring a good air supply for its combustion. If the air supply is checked, it deadens very rapidly and takes some time to rekindle. For this reason, it is unsuitable when the speed has to be frequently altered; but for steady speed steam can be more easily maintained. Its special advantages are a practically entire absence of smoke and a very small percentage of ash, the former being a great contrast to all the Australian and New Zealand coals that have been used, which give off very large quantities of dense smoke."

A very favourable opinion of this coal was given last year by the late Sir Frederick C. McCoy, of the University of Melbourne, who described it as "a true coal and of great commercial value."

RESULTS OF TRIALS ON H.M.S. "ROYAL ARTHUR."

Comparison of the steaming qualities of Westport (N.Z.), Metropolitan, Lithgow, and Collie coals (Australian).

Duration of trials:—21 hours.

	WESTPORT, N.Z.	AUSTRALIAN.		
		Metropolitan, N.S.W.	Lithgow, N.S.W.	Collie, W.A.
Dates of trials	11th June, 1898.	3rd & 4th May, 1898.	13th & 14th July, 1898.	24th & 25th June, 1899.
Average coal used in making the distance logged per hour ..	33·5 cwt.	43·3 cwt.	45·5 cwt.	58·4 cwt.
Steam pressure	125 lbs.	125 lbs.	125 lbs.	120 lbs.
Revolutions per minute	52	55	55	58
Force of wind	Bow 4·5	Bow 3	Bow and ahead 2	Astern 2·5
State of sea	Slight	Slight	Smooth	Slight to moderate
Average I.H.P.	1819 9	1874·3	2042·87	1948·3
Average coal used per I.H.P. per hour	2·07 lbs.	2·43 lbs.	2·49 lbs.	3·35 lbs.
Percentage of ash and clinker ..	5·85	21·3	24·72	6·7
Rate of combustion	Moderately quick.	Quick	Rapid	Very rapid
Emission of smoke	Much dense black	Much dense grey	Considerable dense black	Nil
Grate surface in use	356·4 square feet	456·8 square feet.	456·8 square feet	456·8 square feet.
State of ship's bottom	Foul	Foul	Very foul	Clean

Professor Wyndham Dunstan, F.R.S., Director of the Scientific and Technical Department of the Imperial Institute, has just made a very complete charcoal and technical examination of this coal, conducted in the Scientific Department of the Imperial Institute. Professor Dunstan reports that this coal, the principal sample of which was procured from the West Australian Wallsend Colliery (formerly the Government mine), the Collie, "is likely to be of very considerable value. It burns somewhat quickly, giving out much heat and leaving a small percentage of ash." He further says that "although Collie coal cannot be put into the first class, there can be no doubt that it will prove to be a very valuable fuel for the colony of Western Australia, where coal is scarce and where wood is largely depended on for fuel. As a steam-raiser it is greatly to be preferred to wood, and also to many other coals of better composition which produce much smoke when burnt. It will no doubt be employed extensively as a domestic fuel, since it quickly makes a hot and non-smoking fire." Professor Dunstan also suggests that the coal may be employed "in certain metallurgical operations, in which coke is not necessary," and recommends that trials should be made in the colony to determine its value as a gas-producer.

A large sample of Collie coal is now on exhibition in the Ducal Hall, Earl's Court.

COWPER-COLES MAGNETIC SCALE COLLECTOR.

THE removal of mill scale from forgings and plates has always been a matter of considerable difficulty, the scale in many cases being 1-32 inch in thickness. The usual practice is to place the iron in a solution containing one part of hydrochloric or sulphuric acid to 10 parts of water for from half-an-hour to 24 hours. The Admiralty specify that all steel steam pipes, boiler and collector tubes, and all plates for boilers are to be pickled in a solution consisting of 19 parts of water and one of hydrochloric acid until the black oxide and scale formed during the process of manufacture is completely removed. The amount of acid consumed in the pickling of close annealed sheets, such as are used for roofing purposes, varies from three cwt. to seven cwt. of muriatic acid per ton of sheets; if sulphuric acid is used, considerably less is required. Muriatic acid is used in preference to sulphuric acid by a large number of manufacturers, because it is cheaper bulk for bulk, and also because it acts less quickly on the skin of the metal, and consequently has less tendency to eat it away. In Worcestershire alone about one thousand carboys of acid, corresponding to some 27,000 gallons of waste pickle, have to be got rid of weekly. During the process of pickling, large quantities of magnetic oxide and scale become detached from the plates, which, if allowed to remain in the pickle to be further acted on by the acid, form a serious source of loss. The present invention has for its object the prevention or diminution of this loss, which is accomplished by means of the apparatus shown in Fig. 1, which gives a sectional elevation of a lead-lined pickling tank, with a scale collector placed in position. The scale collector is placed in any convenient position in the tank, and connected by means of terminals A A to a depositing or

Fig. 1.

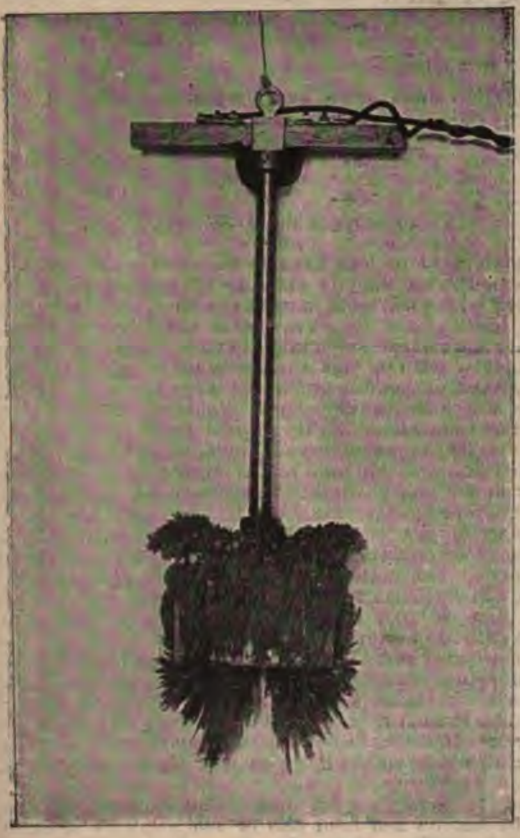

Fig. 2.

electric lighting dynamo, the current required to work it being about ten amperes when an E.M.F. of six volts is employed. In the case of large baths two or more collectors can be employed, or only one may be used, this being moved about to different parts of the bath, at suitable intervals. From time to time the scale collector is taken out, and the adhering scale removed, either by breaking the circuit, or by means of a suitable brush or scraper. Fig. 2 is taken from a photograph of the apparatus after it has been dipped in iron filings; it will be noticed that the electro-magnet has consequent poles—this method of connecting up has been adopted with the object of distributing the field as much as possible.

The apparatus can be attached without difficulty to any ordinary lead-lined pickling tank, and it collects the magnetic oxide or scale almost as soon as it leaves the plate, instead of allowing it to remain in the solution, thus a considerable saving of acid is effected.

THE BLACKMAN VENTILATING COMPANY.

AIR is moved by artificial means for various purposes. It is required for ventilation, for bringing a new atmosphere in place of the old and continually changing it; it is required for combustion at a greater or less rate; it is required for cupola furnaces and for working machinery by the compressed air system. Sometimes the air is made to move by a fan, and sometimes by an engine or blower. Should a high pressure be required a blower or engine must be used, should the pressure be less a fan may be used. When great volumes of air have to be set in motion, a high pressure is not so necessary, and a fan which can take through it great volumes of air at low pressure is wanted. When the draught is high, when it is required to produce a very rapid motion of the air, another kind of fan requires to be used. When the air has to be used at high pressure for engines and other purposes, blowers or direct-acting pumps must be used. One of the most successful fans for setting in motion large quantities of air, that is, for changing the atmosphere is the Blackman fan. When foul air is to be cleared out or the vitiated air of a room to be removed and fresh air brought in, or hot air is to be sent through a room for warming it, then the Blackman fan is got to do the work. It is used in all sorts of places, but we are simply interested in it as a means of ventilating the ship. In looking down the table giving the quantities of air set in motion by any particular-sized fan one is astonished at the enormous quantities. A small fan of 14 in. diameter and 1 square ft. area, making 1,000 to 1,500 revolutions per minute and using $\frac{1}{8}$ to $\frac{1}{4}$ H.P., will cause to go through it 1,000 to 1,500 cubic ft. of air per minute; one 60 in. diameter and 19·6 square ft. area, and using from 1½ to 3½ H.P., will cause to move through it from 21,000 to 45,000 cubic ft. of air; and the largest size in the list of fans, 120 in. diameter and of 78·4 square ft. area, and making 120 to 220 revolutions per minute, will cause to move through it 82,000 to 180,000 cubic ft. per minute. But a curious thing was seen whilst we were being conducted over the works of the Blackman Ventilating Co. in the Holloway Road. One of the shops on the upper floor was ventilated by means of these fans. There were two fans, one at each window of one end of the building, and another fan at a window in the side. Pressure was not necessary, or the spaces between the fans and the sides of the window would have been filled up. These spaces were left as they were. At the ends of the building, however, the fans were set on the floor, the bay of the window being above them. The result was that a draught was induced through the window by the air in movement through the fan. The action of the fan set in the window in the side of the building was just the same. The fan was simply placed in the window, and the effect of the sides not being filled up was not to reduce the effect of the fan, but to increase it. It is said that shoemaker's children are worst shod. This is not the principle held at the works of the Blackman Ventilating Co. These are well ventilated.

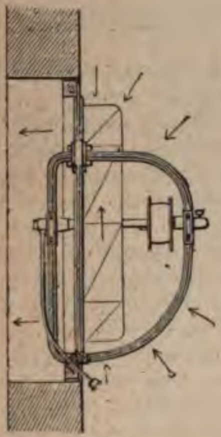

FIG. 1.

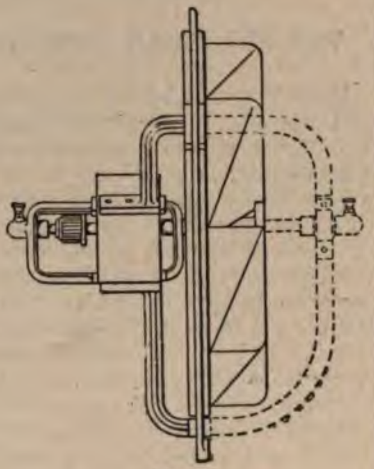

FIG. 2.

The motive power for the fans may be almost any power, but the electric motor, whenever it can be used, appears to be popular. It must necessarily be very economical, since there is no friction consumed at the bearings by the pull of the belt. The first shop we entered, and the first floor above, were devoted to the making and fitting of electric fans. One had been fitted, and was standing on the floor on its edge. It was connected with a switch and resistance-board, and was extemporised by the workmen for producing good ventilation of the shop during the hot season. The fan was run at a fast rate to show what it could do. It could produce a draught equal to $\frac{3}{4}$ in. of water when running at 600 revolutions per minute.

The shops had just been extended. All they had, a short time ago, was the present machine-tool shop; but the extensions are quite equal in area to the old works. In the new shops there have just been laid down a 35-H.P. gas-engine and four dynamos. One dynamo is alternating, and direct for testing purposes. In the centre of the shop space are the stores, with doors at each end, so that stores can be conveniently taken away. At one end of the machine-shop the workmen are making wheels. Everything is made to gauge. Castings are bored to gauge on a boring machine with four heads. The holes are not centred, but the drill works in a template, and no error can be made by the workman. At another place were the field-magnets of motors, made of steel, to work at 500 volts. Every fan has its pulley, and there are thus as many key-ways as there are pulleys and motors. A machine cuts the key-way out in one stroke. The cutting tool is a long bar with a number of cutters on its under edge, each getting deeper by the depth of a cut until the last one is reached, which has the proper depth of the key-way. It can cut from 60 to 100 key-ways in an hour, all of them with the proper taper to be given to the cottar. The works' main shafting is driven by a 16-H.P. gas-engine at the end of the shop. The vanes of the fans are sometimes made of brass, sometimes of manganese steel, and they are stamped out to shape and cut out with a press worked by hydraulic power. There is a stove for drying the armatures. The electric stores are well arranged. Shelves of the sections for different-sized commutators have been fixed up, and the soft iron core sheets when fixed on the spindle only require the milling machine tool through them for the spaces, and the turning of a thin cut off the periphery to reduce them to the proper size.

After this description it will not be surprising to learn that there are now over 40,000 Blackman fans at work, and the average size is so considerable that they are capable of moving 1,000,000 tons of air every hour.

The illustration (Fig. 1) shows the Blackman fan as usually supplied. The position of pulley is varied to suit circumstances. Fig. 2 shows a fan combined with electric motor, shown on its discharge side. The motor is placed on the feed side whenever required. The dotted lines show arms which are used in larger sizes of fans.

MR. BENJAMIN MARTELL.

IT is our duty in this issue to chronicle an event in connection with Lloyd's Register of British and Foreign Shipping which we feel sure will be received with interest by a large number of our readers in view of the wide and extensive celebrity and eminence attained by the gentleman, Mr. Benjamin Martell, who for the past twenty-six years has occupied the responsible and onerous position of chief surveyor to this important and extensive institution. We refer to the fact that on August 3rd the committee of Lloyd's Register accepted with infinite regret the resignation of their chief surveyor. We feel sure that this announcement will produce a genuine feeling of sorrow on the one hand that this gentleman has thought it desirable to sever his connection with an institution which he has so largely contributed to foster, maintain, uphold, and advance by the scientific construction of shipping; whilst on the other hand it is a matter of gladness and good feeling to think that Mr. Martell has retired with a prospect of many years before him to enjoy the leisure which his active and well directed life has so amply entitled him to.

It is no empty statement when we say that Mr. Martell has been for many years a very conspicuous figure in the shipping world, and the nature and general scope of the work carried out by him in such a masterful and thorough manner has been the means of creating for him a large number of friends and admirers in the shipbuilding, as well as the shipping and scientific, world.

When one bears in mind that during the twenty-six years that Mr. Martell has been one of the principal advisers of Lloyd's Committee, some of the most radical and far-reaching changes have been made in the matter of shipbuilding, an industry which is perhaps one of the, if not the, greatest in our empire, one cannot help being struck by the diversity of conditions and the wide area of thought that must have been passed through by Mr. Martell during this extensive term of service, involving great responsibilities. It must be remembered that in carrying out the duties of his office, very serious problems have had to be settled upon a safe and reliable basis, at the same time not neglecting to take advantage of any improvement in the arts and sciences which might fairly be expected to improve the efficiency, utility, and safety of a ship. We may remind our readers that since 1873, when Mr. Martell first took up the chief surveyorship, we have passed through the most marvellous period of advancement in shipbuilding yet known viz., the change from wood to iron, then iron to steel, the transition from sail to steam, from small ships to gigantic leviathans, from the compound to the triple and quadruple expansion engine, and from 7-knot vessels to magnificent liners of over 20 knots speed. It must not be forgotten also that in many cases every step forward made was one made substantially in the dark, there being practically no results from past practice to prove or bear out the correctness or otherwise of the conditions which were brought into play under the new circumstances.

Besides the excellent work which Mr. Martell did in reference to the use of mild steel for shipbuilding purposes, he took a prominent and influential part in the discussion of the important question of the load line, and the results of his first investigations were submitted to the Institute of Naval Architects in a paper read by him in 1874, and it is a fact worthy of note that the data given in that paper substantially constitute the basis of the freeboard tables since legalised by Parliament, and now applied to British mercantile shipping. In this connection no doubt his work was materially assisted by his friendship with the late Sir Thomas Gray of the Board of Trade.

Like many of his colleagues Mr. Martell received his early training in the Royal Dockyards, and first became a Lloyd's surveyor in 1856, when he was appointed to the post of Sunderland, where he remained three years. He proceeded successively to Greenock, Southampton, and again to Sunderland, and in 1869 he was promoted to the chief position of the Newcastle office, whence in 1873 he was promoted to the post of chief surveyor to the society. It will thus be seen that before attaining the high position which he is now vacating, Mr. Martell had a very varied and valuable experience, which, no doubt, has served him exceedingly well during his many years of responsible work.

In entering upon his duties of chief surveyor, Mr. Martell had to follow, in the person of the late Mr. Waymouth his predecessor, a gentleman of eminent standing, great experience, and marked ability, which without doubt must have tended to increase the responsibilities and difficulties in taking up the reins of office. Quite apart from his technical ability, Mr. Martell owes his success mainly to the sound judgment and great ability displayed by him in dealing with the conflicting interests which so often arise in the building of a ship as between the owners and shipbuilders, and that he has been successful is evidenced by the great respect and admiration so generally felt for him by those who have been able to appreciate his ability.

It is not only in his official capacity at Lloyd's, or on the various committees upon which he has served, that Mr. Martell has expended his energy; but as a member of council and vice-president of the Institution of Naval Architects he has been most assiduous in promoting the welfare of this society, and his presence at most of the meetings was the rule rather than the exception.

It has been our pleasure and privilege to know Mr. Martell intimately for many years, and we take this opportunity of saying that we sincerely hope that he may have many years of health and happiness to enjoy his well-earned retirement and rest, a consummation which his earnest and useful work so richly entitles him to.

Japanese Institution of Naval Architects.—The second annual meeting of the Japanese Institute of Naval Architects took place at Tokyo on July 15th, when the following papers were read:—"About Dry Docks in Japan," by Mr. Tsunekawa; "On S. Tsutsumy's Patent Composition to Prevent Leakage of Marine Boilers," by Mr. Iwata; "About Shipbuilding in Shanghai," by Prof. Miyoshi; "American Navy, Past and Present" (illustrated by about 200 magic-lantern pictures), by Captain-Constructor Sakurai.

RADIATING, DRILLING, BORING, TAPPING AND MILLING MACHINE.

THE lessons that the Americans have been giving our tool-makers for some years past are being rapidly taken to heart, and there are plenty of examples of machines now put upon the market as evidence of this fact. The old idea of having a machine which can only do one particular class of work is quickly vanishing, and we have the pleasure to describe and illustrate a very ingenious tool made by Messrs. Neville Bros., of 14, Water Street, Liverpool, which is capable of drilling, boring, tapping, and milling, with a large variety of movement and adjustment of the operating tool.

The four illustrations which are adjoined are produced from photographs of the machine in various positions, and are so clear as to render a lengthy description unnecessary, as they show at a glance the mechanism and utility of the machine. The special feature of the machine is the radial arm, which can be revolved in a complete circle by means of the junction box containing the gear wheels, through which the motion is conveyed to the tool, and enabling it to be placed vertically, horizontally, or at any angle to the work on the table, as shown in Figs. 1, 2, and 3 respectively; or when the table is swung out of the way, to work on the base plate of the machine, as shown in Fig. 4. Thus one of these machines will do the work of a vertical, a radial, and horizontal drilling, boring, tapping, and milling machine.

The frame is of box pattern, with planed slides for the saddle carrying the table. The table is rotary, and has a slide with ⊥ slots, so that any part of the work can be quickly brought under or opposite to the tool. The table is raised and lowered automatically by means of bevel wheels on the counter shaft; these parts, however, are not shown very clearly by the illustrations. The table is hinged, and can be swung completely out of the way of work placed on the base plate, as before described in reference to Fig. 4.

The driving motion is double-geared, and all the wheels have dust-proof casings. The drill-spindle is of steel, and has self-acting and hand-variable feed motion. The tool is made in two sizes, the latter of which has a drill-spindle of $2\frac{3}{16}$ in. diameter, having a depth of feed of $11\frac{3}{4}$ in. It will admit of work 3 ft. 11 in. in diameter. The length of the table is 26 in., and its width 20 in.

NAVAL MATTERS—PAST AND PROSPECTIVE.

(From our own Correspondents at Home and Abroad.)

The Manœuvres and After.

THE majority of the vessels which took part in the Naval Manœuvres held in the early part of last month have now gone out of commission, and are once more in the Fleet Reserve. As was expected, a few have been commissioned for service on foreign stations. It is to be regretted that the fog prevented the "A" fleet from discovering the convoy, and that Admiral Domvile had such an easy victory, as otherwise some very valuable lessons would have been learnt; whereas now one can only guess what might have happened, and reason on that. Admiral Domvile's aim was, of course, to get in touch with the convoy as quickly as possible, and he made his dispositions with this end in view. Soon after he left Milford he found that if he

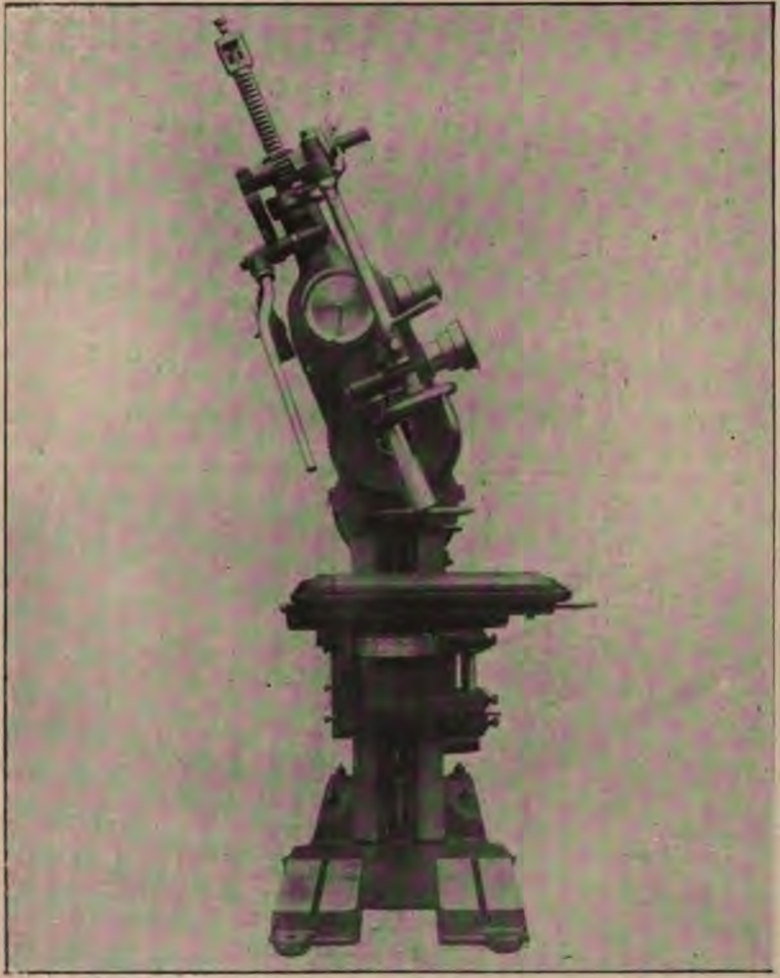

FIG. 3.

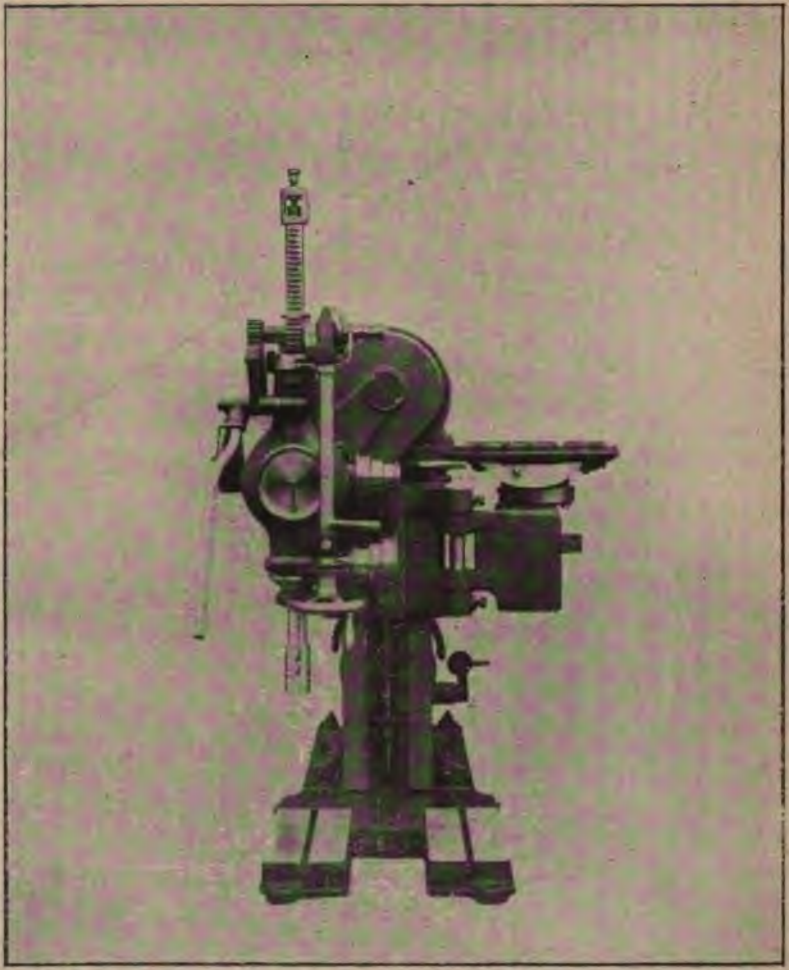

FIG. 4.

RADIATING, DRILLING, BORING, TAPPING AND MILLING MACHINE.

kept the *Thunderer* company his fleet could only steam at 10 knots, and she was therefore dropped. He then proceeded at 12 knots, and a little later the cruisers he had sent out to locate the convoy sent back word by the means of the Marconi wireless telegraphy that the convoy was in their charge, and that they were steaming back to the squadron. He reached Milford with his battle squadron without any further incident. The cruisers sent out by Admiral Domvile managed to capture a couple of the enemy's cruisers, the *Pactolus* and *Furious*.

Results of the Operations.

From the first it could be seen that Admiral Rawson did not have a very good chance of finding the convoy, even if there had been no fog, and he had been supplied with the Marconi system of wireless telegraphy. The latter certainly did not help "B" fleet to score over its rival, but the employment of this means of communication would have given Admiral Rawson a better chance, and the thick weather would not have hindered him so much as it did. Both admirals played the game as they ought to have done, but did not have an equal chance of victory. Admiral Rawson's start of 19 hours was not sufficient, yet if he had risked a little more and had sent cruisers straight to the spot indicated by the correspondents of the *Times* and other papers, he would have been successful in finding his enemy, for, as it turned out, the correspondents were only a few miles out in their calculations. Very little fresh light as to the value of cruisers as scouts has been shed by the operations. The only genuine success, as a matter of fact, is that achieved by the Marconi system of wireless telegraphy. It was demonstrated that messages could be sent over a space of 30 miles. The only difficulty was to decide whether a vessel fitted with a receiver, and within a radius of 20 or 30 miles of the *Europa* or *Juno* could have taken in messages which passed between these two latter. If Admiral Rawson had had some of his cruisers fitted with Marconi's system of wireless telegraphy, this would have been settled, although there is little doubt that it would have been in the affirmative provided the vessel had been fitted with a sympathetic receiver. However, it is reported that Signor Marconi has now solved this question. Altogether it cannot be said that the Naval Manœuvres of 1899 have fulfilled their great expectations.

Coaling at Sea.

The special correspondents and naval experts of various daily papers have often held forth in the columns of the journals to which they are attached in favour of having special colliers built to accompany a fleet to sea in order that that fleet need not be under the necessity of having at any time to put into port to obtain coal. On the face of it, the scheme seems to be a good one, although there are points in it which need consideration. The colliers accompanying a fleet must first and foremost be able to steam at the same speed as the fastest battleship in it, and nearly all the colliers should be built on a uniform plan. At the present time there are very few colliers alike in build, and this causes grumbling and delay, the openings through which the coal is delivered being seldom found in corresponding places. In a letter to one of the daily papers, Commander W. L. Down suggests that all colliers employed by the Admiralty should be built to a certain plan to satisfy the requirements of the Navy. He thinks that the construction of two classes of colliers, differing merely in size, would meet our present wants. Each class should be constructed on uniform lines, so that the length of the ship and the position of holds and transporters would be known when once it was ascertained to which class a coming collier belonged. If this were the case, all preparations for coaling a ship at sea could be made before a collier came alongside. Commander Down is sanguine that if a design for such vessels were prepared at Whitehall it would be adopted by the large coaling firms.

Portsmouth Dockyard.

The Naval Manœuvres over, the majority of vessels sent out from this yard are once more out of commission, and demobilisation has been the order of the day. Many of the cruisers fitted with water-tube boilers that have returned to this port report that they suffered from loss of water, probably due to the leaky joints or defects in the evaporators. The only ship which has sustained any damage during the operations was the *Chamois*, which should by this time be out of dockyard hands. The usual examination of ships and buildings took place, but the work of the new battleship *London* probably attracted the most attention. It is said that the Lady Mayoress of London will perform the christening ceremony, and that the Lord Mayor and many other civic officials will attend at the launch. The news that the new president of the dockyard was to be Rear-Admiral Pelham Aldrich was received with a good deal of satisfaction. Admiral Pelham Aldrich's last command at this yard was as captain of the surveying ship *Research*. The *Andromeda* is to be commissioned on the 5th of this month for the Mediterranean Station. The *Sheldrake* has just gone out of commission after having completed her experimental trials with the Babcock & Wilcox boilers, and the gunboat *Seagull* was to have been commissioned two days ago for a series of trials with the Niclausse boiler. A brilliant example of heroism has been published in connection with the disaster on the *Bullfinch*. The story goes that a man named Dennis, employed at the port engine, rushed to the starboard engine, and stopped the machinery immediately after the accident, when pieces of machinery were flying about in a cauldron of deadly steam. Although he succeeded in stopping the engine, he perished in the attempt, whereas had he thrown himself down on his hands and knees on the port side he would probably have been living to-day. The annual inspection by the Lords of the Admiralty took place three weeks ago.

The French Navy.

Amid the din caused by our own Naval Manœuvres, very little notice has been taken of the manœuvres carried out in the Mediterranean by our friends across the Channel. The men of the Naval Reserve mobilised were given a month's training before they were disbanded, and the instruction given during this period has been of the best, judging from the programme of work. One of the most important operations was that carried out by Rear-Admiral Escande, which lasted over five days. With his division of guardships he anchored at night with all lights out in a suitable spot on the coast between La Ciotat on the west, and St. Tropez on the east of Toulon, and there awaited an expected attack by torpedo boats. Elaborate preparations were made to resist this attack, but it was one of the rules that searchlights were not to be used unless an attack was pressed home. One flotilla of torpedo boats proceeded from Corsica and the other from Toulon, meeting at Tamavis Bay, and leaving there in the evening to search the coast. Creeping along the shore near Lavandon Bay to the east of Cape Benat, the flotilla from Corsica discovered Admiral Escande's squadron lying in the bay, and at once attacked. The result, however, appears to have been that no warships were struck by torpedo boats, but that some of the boats were supposed to have been sunk by quick-firing guns. The main objection raised against the new regulations setting forth the authority and responsibility of the chief of the French Naval General Staff is that they are based upon the duties of our own First Sea Lord. Rear-Admiral Caillard, chief of the General Staff, will in future be immediately responsible for the arming and mobilising of the French Navy, and the Naval General Staff, and Central Naval Administration are to be directly under his command. He will select officers for the various ships and stations, and submit their names for approval to the Minister of Marine, and will also deal with matters appertaining to the promotion of officers and the appoinments for shore service. He will also generally act as adviser to the Minister of Marine. Following on the launch of the *Suffren* at Brest, 190 days from the time of laying her keel, comes the launch of the battleship *Henri IV*.

Warships in Collision.

Two rather serious collisions have occurred within the last few weeks, for which the fog, which did so much towards spoiling the interest at first taken in the Naval Manœuvres, appears to have been responsible. One of these collisions only was attended with loss of life. The *Sanspareil*, flying the flag of Rear-Admiral Aldrich, came into collision off the Lizard with the three-masted iron schooner *East Lothian*, vessel of about 1,500 tons net register, bound from Nantes to Cardiff with ballast. The *Sanspareil* struck the *East Lothian* near the break of her poop, causing her to founder in a few minutes. All on board the merchantman, with the exception of three men, clambered on board the battleship. These three men fell into the water, and, although the man-of-war's boat picked up two in time, the third one was drowned. The other accident was the collision which occurred between the despatch vessel *Surprise* and the collier *Netley Abbey*, off St Alban's Head. The collier is an iron vessel of over 1,000 tons register, and was loaded with coals for the Russian Navy, and bound for Cronstadt. Owing to the thickness of the fog the two vessels only became visible to each other when close together, and were, at the time of the collision, proceeding in opposite directions. The collier was practically drifting, when the *Surprise*, steaming at eight knots, ran into her. Some two or three feet of the bows of the despatch vessel were for some time wedged in the beams of the *Netley Abbey*, and the shock was so great that the whole of the framework of the hull of the *Surprise* under water is said to have been affected. Directly it was seen that the collier would have to be abandoned, the crew climbed on board the *Surprise*, which then went at full speed astern and tore herself free, the collier sinking 20 minutes later. Pumps and collision-mats had to be brought into use to bring the *Surprise* into harbour. The result of the court-martial held subsequently was that the officers of the *Surprise* were practically exonerated from blame.

Devonport Dockyard.

The chief event at this yard last month was the two days' visit paid by My Lords of the Admiralty. Mr. Goschen allowed very little to escape his observation, and although his manner does not give one the idea that he is very energetic, yet he stood the fatigue of inspecting each establishment well. Their Lordships expressed satisfaction with the progress made in the various ships under construction. The *Bulwark* has now had nearly 5,000 tons built into her, which is a slightly better average than that attained by either the *Ocean* or *Implacable*. She will be launched on the 20th of October next. The chief trouble in connection with the completion of the *Implicable* and the building of the *Ocean* is the non-delivery of plating, but it is hoped that this difficulty will be overcome before long. Of the ships refitting here the *Edgar*, when completed, is to be used in taking out reliefs to the Australian station, a duty which she performed previously to the satisfaction of all concerned. During the whole of the time that she served recently as a transport cruiser no serious difficulty of any kind was developed in her machinery. The court of inquiry into the disappearance of the 11,000 gallons of olive oil from the storekeeper's department of this yard has been adjourned until returns can be made of the correct amount of oil contained in each vat, as it is stated that in some cases the vats contain more oil than their indicators record, and considering that there 13 vats, each capable of containing 25,000 gallons of oil, there is a probability that in this way the disappearance will be accounted for. Berthing accommodation for 470 officers and men is to be provided on the new second-class cruiser *Hermes*, the largest crew ever carried by a second-class cruiser.

The German Naval Manœuvres.

Nowadays every country possessing a navy, or part of one, goes in for manœuvres, and therefore Germany was obliged to allow her squadrons to face each other in mimic warfare. The manœuvres proper have not yet commenced, but from the 5th inst. to the 15th, a series of offensive and defensive operations will be carried out in the North Sea. The two squadrons commenced tactical exercises in the Baltic on the 21st ult., and finished on the 25th. The first consists of the *Kurfurst Friedrich Wilhelm*, *Brandenburg*, *Weissenburg* and *Worth*, and the *Baden*, *Baiern*, and *Sachsen*, and the second squadron of the armour-clads *Hildebrand*, *Frithjof*, *Beowulf*, *Siegfried*, *Aegir*, and *Odin*. A reserve division has also been formed of certain armoured gunboats, two light divisions of small cruisers and despatch vessels, and two torpedo flotillas. A pamphlet, which has aroused a good deal of interest in German naval circles is that published by Vice-Admiral Valois. He holds, as do the naval experts of many other countries, that the proper way to attack England is to build a large number of cruisers and prey upon her commerce, and states that the naval preparations of his country must be directed against Great Britain. The pamphlet has been adversely criticised, however, by some of the leading German newspapers, who pertinently ask what would happen to the coast of Germany, her commerce, her trade, and her industry during the course of a long contest for the destruction of England. As the *Times* correspondent at Berlin points out, the object of the present naval propaganda may be the creation of a fleet able to dispute with England the command of the sea, but it is extremely doubtful if this object will ever be realised

The Shooting of Jules Lothe.

The unfortunate death of a French fisherman caught in the act of poaching in English waters has caused a good deal of ill-feeling between the fishermen of the north of France and those of this country. No blame can possibly attach to the commander of the *Leda* for the accident, despite the official report of the captain of the lugger. The latter declares that he was fired upon both by the *Leda's* whale-boat and from the gunboat herself, and that the fatal discharge was fired as the vessels were side by side. He further says that the gunboat could have arrested him without firing upon his boat. Every means of stopping the *Etoile de la Mer* was tried before it was found necessary to fire upon her, and if anyone is responsible it is Captain Delattre. It is ridiculous to suggest that the big guns of the *Leda* might have been used to disable the fishing-boat, especially at night, and considerable loss of life might also have resulted from ramming, so that the course adopted by Commander Maud was the only one left open. Several of the French papers have expressed their regret that the *Leda* did not exhaust every means of capture before firing, although it is admitted that the commander was within his rights in doing so. The expression of regret is wasted, for it was amply proved at the Folkestone inquiry that every chance was given to the Frenchmen of surrendering before extreme measures were taken, and the fact that the chase occupied an hour and a quarter verifies this.

Chatham Dockyard.

All the cruisers specially commissioned at this port for the Naval Manœuvres have now been paid off and put out of commission, so that the yard has once more resumed its normal appearance. There were several defects requiring attention, in the ships of the destroyer instructional flotilla, in readiness for the cruise which commences on the 5th of this month. It is probable that the *Venerable*, which was commenced on January the 2nd last, will be launched early in November, although the launch was originally fixed to take place about the middle of this month. The delay has been caused by the outgoing of Admiral Andoe and the incoming of Admiral Holland. Preparations are being made here for a new battleship to be commenced on the slip vacated by the *Venerable*. The vessel will be of the same type as the *Duncan* and the *Russell*, recently commenced at the Thames Shipbuilding Co.'s yard. £10,000 is to be spent upon the refit of the *Hawk*, which struck her pennant early last month, after having served on the China Station for six years. The *Irresistible* should by this time have her submarine tubes and underwater fittings completed. She will probably be ready for sea by the middle of next month. Instructions have been received that the *Goliath* is to be completed as quickly as possible, in order that her gunnery trials may at once take place. The *Dreadnought*, which, it will be remembered, grounded on the shingle bank off Shoeburyness just as her gun-mounting trials were to take place, will have to be docked in order that the damage done to her keel can be attended to. The Admiralty propose to spend the sum of £20,000 on a new building slip for this yard during the current financial year. Very little, however, has been done up to the present time. The refit of the *Immortalite* is to be completed by the end of December, and although the spending of £30,000 on repairs to her hull and machinery has not yet been approved of by the Admiralty, the work is to be taken in hand at once.

Speedy Cruisers.

It has been stated by many well-known engineers that the turbine-driven steamship will in all probability make its appearance before the twentieth century is far advanced, and that it will mark a new era in the history of steam. The Hon. C. A. Parsons, the owner and designer of the *Turbinia*, is presumably of this opinion, for in *Cassier's Magazine* he has a most readable article on the development of the turbine and its application to naval purposes. He is in favour of the building of an armoured cruiser fitted with his invention, and hints that the construction of such a vessel will be attempted before long. The ship would be of 3,000 tons displacement, 450 ft. length, 42 ft. beam, and 14 ft. maximum draught of water, carrying turbine engines and boilers of 120,000 maximum H.P., the boilers being of the water-tube type arranged in two tiers. This vessel, he continues, could steam economically at 16 knots speed, but would in an emergency be capable of increasing her speed to 48 knots, and maintaining this speed for three hours, or she could maintain a speed of 45 knots for eight hours. She would be difficult to hit with shot, and her speed being 18 knots greater than that of any locomotive torpedo, she would well take her chance in this respect. Mr. Parsons thinks—and it is just possible he is right—that a few vessels of this kind would be valuable additions to the British Navy.

They would be valuable additions to any navy, provided they could be built and made to answer expectations. Perhaps the company in which Mr. Parsons is interested intend constructing an experimental vessel.

General Willis and the "Naval Annual."

The attack made upon the *Naval Annual* by General Sir G. Willis has done little more than make that officer appear foolish in the eyes of those interested. He suggested that the book contained confidential information such as would be valuable to foreign Powers, but this was entirely disproved. It was admitted that the Admiralty had occasionally given assistance to the editor of the *Annual*, the Hon. T. A. Brassey, but nothing which would have been refused to other publications if asked for. General Willis has only just discovered that in one of the volumes published many years ago, the most secret details pertaining to the Spithead and other forts for the defence of our shores, which never could be known to an enemy if they had not been printed and depicted in that book, had been given. Now, the article in question distinctly stated that the information was a series of extracts from a lecture read by Colonel Inglis R.E., at the Royal Artillery Institute, Woolwich, in 1880, and if anybody knew this, Sir George Willis ought to have done so It should be mentioned that the *Naval Annual* was produced at a loss for several years after it was first started, and it is now admitted to be the best and most authentic publication of its kind The real cause of the attack on the *Naval Annual* apparently lies in the fact that the Hon T. A Brassey, the editor of the *Annual*, is a candidate for Parliament for the Christchurch Division of Bournemouth, and that General Willis is presumably opposed to his election. In view of the answer he received in the House of Commons he ought to tender an apology to Mr. Brassey.

Sheerness Dockyard.

A large amount of overtime has been worked at this yard recently, but it is probable that some cessation will now take place, as the Admiralty have directed that overtime is to be reduced as far as possible. The machinery and boilers of the new sloop *Condor* have now been delivered, and it is expected that she will be completed some time before the *Rosario*. She is the first sloop to be fitted with Belleville boilers, with which the *Rosario* is also to be supplied. Both ships have been masted, and, we are told, are to be rigged upon similar lines to the *Torch* and *Alert*. A good deal of work will have to be put into the gunboat *Niger* before she is able to resume her coastguard duties in Scotland. There was a great deal to do to her when she came here in July to have her defects attended to, and when she was despatched for the manœuvres part of this work was still unfinished. The annual overhaul and repair of the *Alarm*, a vessel of the same class as the *Niger*, has now been completed, the vessel having been in hand two months, and she is now quite ready once more to resume her work in the North Sea. The gunboat *Goldfinch*, which is returning home after serving three consecutive commissions on the Australian Station, is to be immediately taken in hand for a further period of foreign service. The *Perseus* is to be completed in readiness to commission on the 25th of this month for service on the Mediterranean Station, where she will relieve the *Salamander*.

The "Ocean" and "Canopus" on Trial.

According to all accounts, the preliminary trials of the new first-class battleship *Canopus* were not as successful as could be wished for, but too much importance should not be attached to the results of the one-fifth power trial. The *Canopus* lost a good deal of water owing to leaky joints in her tubes, and this probably accounts in some degree for the unexpectedly high coal consumption. On the other hand the preliminary trials of the *Ocean*, a sister ship, are said to have been very successful. The conditions of the second 30 hours' coal consumption trial were that a mean I.H.P. of 10,000 should be developed continuously whilst it was in progress. The *Ocean* successfully carried out these requirements, the machinery working without a hitch. The mean results were :—Steam in boilers 258 lbs.; at engines, 221 lbs.; vacuum—starboard, 27 in.; port, 26 in.; revolutions—starboard 101·9, port 103·1; I.H.P. —starboard 5,084, port 5,230. Total, 10,314; air pressure, *nil*; speed, 16·2 knots; coal consumed per I.H.P. per hour, 1·6 lb. The coal consumption of her full power trial was not taken, but the speed obtained is given as 19 knots. Three of the class of ships to which the *Oceana* and *Canopus* belong will, early next year, be ready for the pennant, there being the *Goliath* building at Chatham, in addition to these two. It may be mentioned here that the *Goliath*, at Chatham, has now received all her armament, and that she is to commence her gunnery trials almost at once.

The "Powerful" and "Terrible."

It has more than once been suggested in these columns that if the *Terrible* had been sent away to a foreign station in the same way as the *Powerful*, she would have been by this time as great a success as this ship has proved herself. The news to hand, that at last this course is to be adopted, suggests that the Admiralty are also of this opinion. The *Terrible*, in fact, is to be sent to relieve the *Powerful*. According to an account recently received from the China Station, the *Powerful* has made another successful trial. Leaving Hong Kong on June 14th for Wei-Hai-Wei, she steamed at easy speed for three days, but when within 600 miles of Wei-Hai-Wei she started on her full-power quarterly trial. According to one report, the coal was small and the boilers dirty from previous use; but despite these drawbacks, the *Powerful* managed to keep up a speed of 20·8 knots for four hours, with H.P. of between 24,000 and 25,000. For the next 12 hours the vessel went forward at a speed of 20 knots, and would probably have kept this up for a longer time had not a dense fog come on and caused her to slow down. We are informed that during the run everything worked well, and that no defects of any kind revealed themselves. This demonstrates in the clearest manner that the water-tube boiler is not nearly the failure which Mr. W. Allen, M.P., would make us believe. There is little doubt, however, that the fleet engineer of the *Powerful* has had a great deal to do with the successful working of the *Powerful's* machinery, as Mr. Edwards, in addition to being a thoroughly practical administrator, is a man of science, and must have worked up those under him to a high state of efficiency to obtain such favourable results. The *Powerful* will probably make a record passage home.

Pembroke Dockyard.

It has been found that it will not be necessary to remove the non-inflammable wood which has been used in the fittings of the new Royal yacht. This wood has been chemically treated, and can now be painted in a proper manner. It was originally thought that, as a result of the chemical treatment to which the wood had been subjected, it would be too wet to paint, but it has now been dried somewhat with the aid of charcoal fires. A similar course, it should be mentioned, has to be adopted where the wood is used in vessels of the Navy of the United States. The new yacht is to be sent to Portsmouth for completion next month. She will probably be ready for commission next summer. It is rumoured that the command of the present Royal yacht is to be given up by Admiral Fullerton on account of ill-health, and that she will be taken over by Captain Curzon Howe, whose period of service in the traning ship *Britannia* terminates in April next. The cruiser *Spartiate*, which is completing at this yard, has had all her funnels placed in position, and altogether good progress is being made on her. She was laid down in May, 1897, and launched at the end of October of last year.

The Water-Tube Boilers during the Manœuvres.

Immediately on top of the denunciation of the water-tube boiler in the House of Commons by Mr. W. Allen, M.P., the reports came to hand of many successes achieved during the recent manœuvres with this type of boiler. The thick clouds of smoke that poured from the funnels of the new cruisers is, it is admitted, a defect, but one which can be overcome. Great strains were frequently put upon the machinery and boilers of the vessels fitted with the Belleville boiler, but their efficiency was proved by the ease with which they answered every call made upon them. At times the speed of some of the cruisers was increased from 8 to 18 knots in less than three minutes, a feat which would have been quite impossible with the Scotch boiler. The well-known naval writer, Mr. H. W. Wilson, who was afloat as the special correspondent of the *Daily Mail*, considers that "with careful stoking the water-tube boilers make no more smoke than the Scotch type." Of its steam-raising capacity, says he, "no one can have any doubt, and the vessels fitted with it can do their 18 knots at sea with ease for any time with moderately good stokers. It is, of course, where economisers are not fitted, exceedingly extravagant. Where these are carried, the expenditure of coal is nothing startling. For instance, one 11,000 ton cruiser with Belleville boilers (economisers fitted) made the voyage from Portland to Belfast, round the west coast of Ireland, on 343 tons of coal. She did three hours at 18 knots, three hours at 14 knots, 40 hours at speeds of 10 to 12 knots (with steam always in hand for 12 or 13 knots), and some hours lying-to or going at low rates. This consumption included everything. If you want slow ships, put in the Scotch boiler and see enemies steam gaily out of sight."

UNION DOCKS, LIMEHOUSE.

In our last issue we gave a short notice of the opening of a new dry-dock on the premises of Messrs. Fletcher, Son, & Fearnall, Limited. We have now the pleasure to supplement our description, and to illustrate the work by the adjoining diagrams.

Fig. 1 is a cross section of the dock, the pump, well, and engine room. It shows the general design of the body of the dock; there are altars in the side ways of 18 in. and 24 in. in width respectively, placed at levels of 5 ft. and 12½ ft. below the coping, and the side walls have a batter of one in six, with a bold curved base and gutter at the dock bottom. The work is of Portland cement concrete throughout, with a watertight skin of cement compo rendering under the bottom and up the backs of the side walls to the level of Ordnance Datum, which is above the permanent level at which the land springs stand.

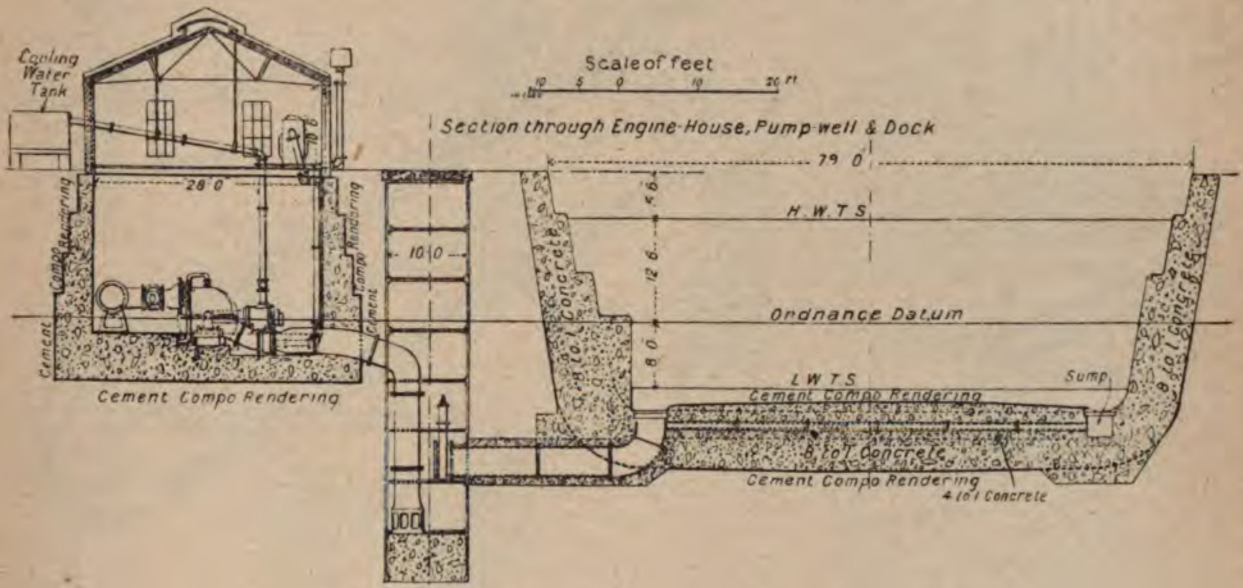

Fig. 1.

For filling the dock with water, sluices have been provided through the gates of sufficient area of opening to fill the dock in 15 to 20 minutes, and for emptying the dock an installation of pumping plant has been erected which will empty the dock without a vessel in it in two hours. This plant, which has been supplied by Messrs. Gwynne & Co., Brook Street Works, Holborn, London, E.C., consists of two centrifugal pumps with suction pipes of 26 in. diameter, each driven by a gas engine of 140 indicated and one pump with a suction pipe of 10 in. diameter, driven by a gas engine of 60 I.H.P. This smaller pump is for drainage purposes. The engines and pumps are placed in the engine room, which is 50 ft. long and 28 ft. wide; the floor is at the level of about 20 ft. below the coping level of the dock.

The pump well is a cast iron cylinder of 10 ft. internal diameter and is sunk to 50 ft. below the coping level. The culvert from the dock to the well and the discharge culvert from the engine house to the river are cast iron pipes 3 ft. 6 in. diameter, surrounded by concrete 12 in. thick. In the well an opening has been provided at a suitable level for a cast iron culvert to connect with the middle and upper docks.

Fig. 2 is a plan of the new Dock, and Fig. 3 is a plan on a smaller scale, showing the relative positions of the upper, middle, and new docks. The engines were made by Messrs. Crossley Bros., Limited, of Manchester, and are of their high speed type, specially designed for driving centrifugal pumps and dynamos. They are supplied with coal gas from the public mains and on full load run 190 revolutions per minute. The engine crank shafts, which are steel forgings, are fitted with heavy cast iron counterbalance weights to ensure steady running. Each engine is fitted with two flywheels 7 ft. 3 in. diameter, and 10¼ in. wide on the face of the rim, and has a high speed centrifugal governor, by means of which the speed of the engine can be regulated while at work. This enables the engine to run slowly when the dock is full, and the attendant can gradually increase the speed as the duty increases. This ability to vary the speed is very important, it is claimed, in order to obtain the most economical working results. Each engine is coupled direct by a centrifugal pump, in one case by a flanged coupling and in the other by a jaw coupling. The latter engine is to be used occasionally for driving a dynamo, hence the necessity for being able to disconnect the pumps.

The 60 H.P. engine which drives the 10 in. centrifugal pump which is for keeping down the leakage in the dock, also drives a vacuum pump for exhausting the air from the suction pipes and cases of the main centrifugal pumps at starting. Each of the pumps is fitted with a sluice valve on the suction pipe and with a sluice and reflux valves on the delivery sides. The general arrangement of the engines is clearly shown in Fig. 4. As seen in Fig. 1, which shows the arrangement of the engine-house below ground, it will be obvious that this arrangement has a twofold advantage. Firstly, valuable space is saved near the dock; and secondly, the length of the suction pipes to the pumps are reduced to a minimum.

It will generally be admitted that undoubtedly gas engines have many advantages over steam engines for work of this class, as the preliminary expenses of raising steam are avoided, and the motive power being always at hand the engines can be started immediately they are required at short notice; and moreover the consumption of fuel ceases as soon as the dock is emptied.

We have had the opportunity of examining the work and can add our testimony that it is of the most up-to date description, the dock being provided with every possible arrangement of labour and time-saving appliances. The new addition to docking accommodation on the Thames should prove of great benefit both to ship owners and the firm who have had the enterprise to bring it into being.

Messrs. Kinipple and Jaffey, of Westminster, were the engineers for the works, and Messrs. Kirk & Randall, of Woolwich, the contractors.

MARINE ENGINEERS' NOTES.

(From our own Correspondent.)

THE scheme for the National Physical Laboratory has been advanced a step. It will be remembered that the Treasury appointed a committee, of which Lord Rayleigh is chairman, to make an enquiry into the necessity for such an institution, and, after an exhaustive enquiry, this committee has brought in their report. The evidence showed that there was a necessity for a place where instruments could have authoritative standardisation and where also researches could be conducted having special reference to the industrial requirements of the country. There are supposed to be facilities for testing and certifying electrical instruments at the Board of Trade, but these are of the most meagre description, and in future such work will be done at the National Physical Laboratory.
